JOHNSON, LONDON, AND MR. R. HOGG, LL.D., LONDON.

VOLUME XXIII, NEW SERIES.
VOL. FOUR, OLD SERIES.

LONDON:
PUBLISHED FOR THE PROPRIETORS, 171, FLEET STREET.

TO OUR READERS.

THE year now closed has been to us in every sense of the adjective a Rosey year, for the dictionary defines that word as applicable to what is blooming, healthy, and cheery, and also to whatever is connected with the Rose. Now we say, without any reservation, that our pages during the past year have been enriched by our contributors with more aids to those who were in difficulties in the culture and exhibition of the Rose than were ever published before by any horticultural journal. Moreover, continuing still to refer to the term Rosey, we gratefully add that our progress merits the term.

To afford information needed by a numerous class of our subscribers we shall add a department "The Home Farm," which we know will be enriched by the meritorious writings of our contributors; and to them, with the Spanish wish, "May their shadows never grow less," once more thanks are given sincerely by

THE EDITORS.

INDEX.

- ABNEY HALL, 272**
Abutilons, 218
Acacia lophantha wintering, 338
Accrington Poultry Show, 23
Adiantum, farleyense, 849, 890; *Lud-*
demannianum, 475

From observations taken near London during forty-three years, the average day temperature of the week is 73.6°; and its night temperature 50.1°.

SPECIAL SHOWS.

IUST as well-managed local horticultural societies stimulate and encourage cultivators in the districts of such shows, so in like manner do special shows promote the more extended and perfect cultivation of that which they were intended to assist. A national horticultural society, however strong it may be, will never of itself be able to satisfy the wants of the scattered thousands who are identified with horticultural pursuits; but a strong central society, with many branches in alliance, is capable of affording valuable aid on various subjects connected with horticulture. A central society may do much good without the aid of district branches, and local societies may also exert a beneficial influence without being in connection with a central head; but both may do more by alliance—the “national” gaining strength by the ramification of its branches, the “locals” gaining influence from their association with the central head.

We should like to regard horticulture as an invading army already established in our land, and seeking to conciliate and render loyal every portion of the community. To that end there must not only be an authoritative central body, but many outlying battalions, each of them strong enough to act alone, yet having a consciousness of greater strength by the support which is in reserve in the other branches of the confederacy. To render the work effective there must necessarily be special efforts made for a special purpose, each important and an integral part of a general design. The more perfect are the several parts and the working of them the more perfect must be the aggregate. It is only by giving special attention to details that a great object can be successfully carried out, whether that object be one of war or peace. The object of the present invasion is emphatically an object of peace. It is the extension of an important industry, the good influences of which are far-reaching. It is the dissemination of that which conveys healthy enjoyment, wholesome gratification, domestic comfort and benefit not only into every city, town, and village, but almost into every home. It is to perfect the fruits of the earth, to bring forth the beauties of Nature in all their fulness, and enable them to be enjoyed by the greatest number. That is the object of the campaign—an object both great and good, so great as to demand all the efforts both of a general and a detailed nature which can be utilised on its behalf—so good that the pursuit is worthy of the countenance of the most enlightened and refined.

The various special societies (with special shows resulting) which are now established are from their prominent position proper objects for criticism, and it is not to be expected that all who are interested in floriculture will place the same estimate on their merits. It is not possible that this can be so, for nearly all of them can be viewed from two distinct standpoints. These special societies can be regarded as “splits” from, and antago-

nistic to, a general central national society; indeed they have been so described in a manner that caused some surprise, and the more so when their tendency was stated “to degrade horticulture.” To that conclusion we certainly cannot give our assent. We do not regard special societies as splits from, but units in the great system of horticulture. By perfecting the several details of a work the whole is being done, and done in a manner that could not be effected so well by any other means. If the members of any of the special societies now established—the Rose, Pelargonium, Carnation and Picotee, Auricula and Polyanthus, Tulip, even the Potato societies—concentrate their efforts on the perfecting of that with which they are identified are they engaged in an ignoble cause? and yet they must be if the tendency of such societies is to degrade horticulture. It is easy to find fault—easy to say that the Rose needs not a society to support it, as it is strong enough and popular enough without special aid; and equally easy to say that the Auricula is not of sufficient importance to have special patronage bestowed on it because so few are identified with its culture. It is easy to criticise, too, for the purpose of filling-up space, which is, perhaps, generally the object when fault is found and errors are not defined. But such criticism carries no weight and goes for nothing with those who understand it and the feelings by which it is prompted.

But the Rose, notwithstanding its great popularity, has during recent years proved itself to be amenable to so great improvement that it not only merits but demands special attention in order that it may unfold new and greater beauty than before, and find still more numerous patrons. So with the Pelargonium: also equally if not more so with the Carnation and Picotee, and the Auricula and Polyanthus. Than these flowers none are more beautiful, none better deserve encouragement, and none will give greater reward for any special efforts which may be made in their behalf—efforts which are specially needed. All who are engaged in improving and extending the culture of those and other florists’ flowers are engaged worthily, for they are prosecuting in detail important branches of floriculture which must improve the aggregate of horticultural work.

Yet while granting the usefulness and importance of special societies as the working units inseparable from a great system, the object of which is higher culture and a widening of public interest in floricultural pursuits, the medal has an obverse, and this we shall not shrink from examining. In societies having a defined object—the cultivating and perfecting of a particular flower—special rules become necessary for judging that flower. A standard is determined on—a charmed circle drawn, the flower is adjudicated on in obedience to that rule, and it must not by any erratic freak trespass beyond the circle—its little world which its friends have created for it. We find no fault with that arrangement. It is right in itself. A standard must be fixed, and it must be a high one. But we will ask this question, What of the flowers beyond—just outside the circle, just below the florist’s standard? Take the Rose, for instance, which

LIBRARY

BOTANICAL
GARDEN.

was in royal session yesterday at the splendid and successful Show of the rejuvenated National Rose Society. What has been the cost of that Show and what its results? Eleven months of care, of watching—pleasurable care no doubt—and almost a chance fixture, has brought the identical Roses to the front which all rosarians knew would receive high honour. With that result, from a rosarian point of view, we are satisfied. We as rosarians prepare for eleven months of labour, and do not expect more than one month of perfect beauty—of shows. The Roses which win our prizes, those noble blooms, have their fame spread throughout the land; and the million of Rose admirers—not rosarians, mind—preserve the names of the prize-winners and order the varieties to make their gardens beautiful and sweet. They dig-up their old trees—those trees which have yielded them blooms for years, and it may be many months in the year—to make room for the new. The nursery-men do the same—they are obliged to do so; and hence the old Roses, the grand old garden Roses which produce hundreds of blooms—small they may be, but they are Roses—lovely, hardy, continuous, and sweet: ought they to become extinct? We think not; and we know, for we have had the best proof of it, that there are many who think with us. Where there is one cultivator of Roses whose chief object is to grow them for exhibition, there are ten who grow them for garden decoration. Many exhibition Roses we are well aware are eminently suitable for garden decoration, but not by any means all of them are. Some of the leading varieties are capricious—"grand when caught." But there are many old Roses which are wholly unsuited for the exhibition stand, yet which never fail to charm in the garden. It is these garden Roses which are becoming scarce. We fear the Rose societies cannot encourage them: they are beyond their pale, but not beyond their influence. We can only appeal, therefore, to Rose admirers who are not exhibitors to cherish the delightful garden Roses, and we advise them not to destroy the old before they have proved the new.

We would refer to other florists' flowers, but space forbids—to the beautiful, but sometimes "miffy," Carnations; to the ostracised Auriculas, especially the Alpines which are so beautiful in the garden, and—perhaps because of it—so vigorous; to the Polyanthus, amongst which those which adorn the garden the most effectually cannot have honour at the shows. All the more reason therefore to honour them in the garden, to improve, and cherish, and preserve them there. Let exhibitors grow and show their flowers with all their ardency and all their skill, they are engaged in a right good work; but forget not the flowers of home—the free, gay, and sweet garden flowers.

There yet remains another feature in connection with special shows that we would notice. It is an important one—even the specialists themselves. Their special knowledge—their advantages—their power are great. Let them wield their strength wisely, considerately. They "mean well," but their earnestness is not always understood by outsiders. A sentence from a letter which we received the other day is illustrative of our meaning. The writer refrained from saying what he wished because, as he said, while Mr. — was no doubt a "good sort," he was "terribly touchous."

SEASONABLE NOTES ON GRAPE-GROWING.

No plant requires less attention than the Vine when it is leafless and at rest, and there are few with greater demands when it is in full growth. We are now in the midst of the Vine-growing season. It is an interesting time in the viney when the bunches are forming, and it is surprising how very rapidly the small bunches increase as the berries begin swelling. This year no person who saw our Hamburgs before they came in flower would have cared to stake their life that one bunch would have weighed over 3 lbs., and now I venture to say that some of them would turn the scales at 5 lbs., if not 6 lbs.; but I rather suspect there is a good reason for this increase of weight, and it is easily explained. Every time the Vines have been watered they have received abundance of strong liquid manure—made not with chance refuse, but the real pure pig and cow dung. I have ceased using guano for Vines, and nearly for everything else. The manure above mentioned is far cooler and much more nourishing.

Nothing more distressing can be seen about a garden than Vines starving for want of food, and it is a melancholy fact that thousands of Vines are actually starved into unfruitfulness. Let barren Vines of last and former years have an unlimited supply of liquid manure for the next two months, and if they

do not improve in leaf and wood and become more fruitful next year they will be different to any I have ever had to deal with. This is all I intend saying about the roots at present; and I now come to what may be considered by Grape-growers generally, but more especially amateurs, to be the leading question at this period of the year.

Ever since I can remember reading the Journal the numbers in June and July have always contained many answers to correspondents on Grapes scalding, and information seems as much sought for this year as formerly; and I must say I am not surprised at this, as it is a matter quite capable of creating great concern. Still, scalding is not always a sign of bad Grape-growing, as the worst case of it I ever saw was with one of your "crack" market growers near London, but I am inclined to think it is the result in a great measure of casual neglect. My own opinion is that the evil does not come from the roots, but rests in the state of the atmosphere. It is not always the berries unshaded from the sun that become first affected; on the contrary, those under the thickest shade often suffer severely. Where ten berries would scald in a close moist warm atmosphere not one would do so in a cool or comparatively cool dry place. The worst cases of scalding I have ever witnessed always occurred in houses where there was much fire heat and sun heat combined. Any person could scald the half of the berries in their house simply by having the pipes hot in the morning and not admitting much air until the temperature rises to about 90°. This will produce a dew on the Grapes, and then they are prepared for scalding.

Some people appear to have an idea that Grapes cannot be grown without fire heat, and, no matter how hot the day may be, the pipes must be hot also; and as for allowing them to pass one night without fire, it is entirely out of the question. That is an expensive waste of coal, and it does no good whatever to the Vines or Grapes. We have a large Hamburg house in which the Vines were in bloom by the end of April. The Grapes are now nearly half swelled and looking extraordinarily well, and all the coal that has been used to supply them with artificial heat does not exceed two barrowloads. Fire heat is never used unless in a wet day, and it will not be used until it is necessary to prevent the ripe fruit from damping. Still the temperature is never very low at night, as we always close the ventilators early in the afternoon, and the sun heat does not all escape until the lights are opened the following morning.

Nearly all Grapes have been thinned, but wherever it is seen that the berries will be crowded when ripe go over them at once and clip them out, so as to leave the bunches looser. We did this to a house of ours a week ago, and the bunches are now filled up as if they had never been touched; but no more will be cut out of them, as they will soon be ripe and cease swelling.

As yet there is not a single red spider on one of the Vines, and this I attribute to giving plenty of water at the roots and keeping the atmosphere sweet, moist, and healthy, combined with little or no fire heat.

Vines are not making young wood so fast now as a month ago, but they are still forming leaves; but they must never be allowed to become large, or they may shade a bunch or a few berries while they are tender, and then by removing the leaves the sun strikes strong on the previously shaded parts and often does damage.

I never shade a Vine from the sun with any covering on the outside of the glass. A Vine, provided it is well watered at the roots, will withstand as much heat or sunshine on its leaves as an Oak will; and wood ripened, or rather browned, in the shade will bear no comparison with that ripened under full sunshine.—A KITCHEN GARDENER.

ROSE SHOWS.

I did not go to the Crystal Palace on the 23rd. Amongst other unacceptable economies they had left out of their schedule the twelve for amateurs, which suited many to whom the twelve triples is too formidable.

"Vessels large may venture more,
But little boats must keep near shore."

One thing they may be congratulated on, and that is having gone back to the one-day show. The Press deserves great credit for the prompt manner in which the two-day enormity of last year has been protested out of existence.

I did go to Maidstone, and a very pleasant and creditable little Show it was. They did not do things, indeed, quite in the

grand style of last year, so attracting all-England prizetakers that Maidstone was voted the best Show of the season—a grand style of scheduling that I fear must have proved rather costly to the Committee. This year the Show was confined to members only. The competition for the challenge cup was spirited, and some good Roses were shown, as also especially in the class of twelve triplets of any kind. Owing to a liberal gift from Mr. George Paul of Cheshunt, four prizes were offered both for twelve and six Teas, and the show of them was very fine. Maidstone in its happy valley must be a paradise of Tea Roses, judging from those exhibited, and is likely, I think, to make these famous before long beyond its own borders.

Reynolds Hole was, perhaps, the best H.P. in the room. The Cheshunt Hybrid was also shown in great perfection. The Briar stock is the favourite in their strong soil. But I do not think the state of Rose-growing altogether satisfactory.

That is a very grave subject which has been started respecting breeding in-and-in by budding, and I incline to think threatens a serious deterioration. It might be discussed with great advantage.—A. C.

EARLY SUMMER FLOWERS.—No. 2.

COLLECTORS of every species and variety of hardy Rhododendrons tell us that there is hardly a month in the whole year when some species or other is not in bloom. Admitting this highly important fact, it must still be granted that it is in early summer that most varieties appear in the full splendour of their regal beauty, giving us such rich masses of colour as we obtain from no other shrub. With all this richness there is nothing glaring, nothing oppressive, when a little pains is given in the first instance to arrange the various colours in graceful combinations—softening the brilliancy of the scarlet-tinged Alarm with the rich purple of Sir Thomas Sebright; relieving this in turn with the delicate white of Mrs. John Clutton, and thence onward through an infinite gradation of shades of white, pink, scarlet, crimson and purple—never in any case affording an unbroken mass of colour, for we find in such mixed beds that every sort does not yield blossom in equal abundance, some answering best in one season and some in another, some plants of a foot or two in height being laden with flowers, while others do not blossom freely till they become large plants. Nor is this want of uniformity to be regretted, the dark green patches of foliage interspersed among the flowers imparting relief and repose in the most agreeable manner. Nature's own foil is always the best.

Some valuable lessons have been had this season in making a study of the effects of the different colours; and I may usefully note here that the most distinct and striking shades are most telling when well placed in the margin and centre of a group, either singly, as is best in small groups, or clumps of three or four in large bold ones. Lists of such sorts are more useful in the autumn than now; but I cannot refrain from pointing out the great value of the dark crimson John Waterer, the rosy crimson Blandyanum, the rich purple Barclayanum, a somewhat shy-flowering variety when the shrubs are young, but growing more and more lovely as they increase in size, many of them this season being one mass of flowers; and such kinds of lighter hue as the old Queen of the West, Minnie, Purity, and Delicatissimum. Much caution should be exercised in discarding any old sorts, many of them possessing some property of earliness, lateness, or continuity of flowering not always found in newer kinds.

The hardy Azaleas are again very beautiful. I only wish the flowers were a little more durable. Many of them were originally planted as a fringe to some clumps of Rhododendrons. This proved a mistake, and last winter they were arranged in separate beds alternating with others of *Kalmia latifolia*, some beds consisting solely of the various shades of Azalea pontica, and others having a mixture of more choice named varieties. These beds have been very telling, the effect being much enhanced by the proximity of large masses of Rhododendrons. Considerable difference is found among these hardy Azaleas not only in colour but in habit of growth. The dwarf compact growth of the brilliant orange-coloured *Majestica* renders it very valuable for many a nook and corner as well as for the margin of shrubby borders. The rich yellow of Nancy Waterer is never more effective than when placed near masses of crimson and purple Rhododendrons; while such lovely sorts as the pink-flowered *Monterii*, *Amœna* of a lighter shade; *Straminea*, delicate straw colour; *Mirabilis*, another pink kind; *Viscocephala*, white; with the lovely old sulphury

white *Pontica alba*, the deep crimson *Géant des Batailles*, *Gloria Mundi*, and *Ne Plus Ultra* with deep rich orange flowers, all tell well in whatever position may be assigned them.

So many shrubs are in flower just now, and all are so beautiful that one hardly knows which to select, or rather which to leave unmentioned. Of the *Kalmias*, *glauca*, in full beauty a month or more ago, is a distinct and valuable early sort; *angustifolia rosea*, *rubra*, and *nana* are all now in full beauty; while the flowers of the queenly *latifolia* are only just beginning to expand. Nothing can be more lovely than a plant of *Kalmia latifolia* just bursting into flower: the thousands of clustering pink-tipped buds springing out of the dark green glossy foliage impart to the plant a sprightly air most pleasant to behold, while not less enjoyable is the sight of the cloud of bloom into which they soon expand.

The pendant golden flowers of the *Laburnum* just fading away have imparted their peculiar charm of grace and brightness to the shrubs among which they grow. *Lilacs*, pink *Thorns*, *Guelder Rose*, *Magnolias*, *Snowy Mespilus*, *Berberis*, *Daphne*, *Ribes*, *Philadelphus*, and some of the *Spiræas* have all lent their charms, not singly but in many varieties, all being good; but especial attention should be given to *Philadelphus grandiflorus* with very large white flowers, an immense improvement upon the old small-flowered sort. The very dark scarlet *Ribes atro-sanguineum* proves a most valuable and effective variety, as does also the double-flowered variety, coming into bloom so late as to form a succession to the single-flowering shrubs.—EDWARD LUCKHURST.

PORTER'S EXCELSIOR POTATO.

ALTHOUGH not an extensive grower of novelties I yet like to try, in a small way, some of the new Potatoes as they come out; and amongst others last spring I procured 1 lb. of Porter's Excelsior for trial. One tuber was decayed and worthless; the others were cut into nine sets to suit the length of drill, as they were simply for comparative trial and not for special increase. This row is between Fenn's Early Market and Lye's Favourite, and is very distinct from these varieties; but unfortunately the plants are distinct from each other, although a casual observer might not detect the difference. As I never before saw the sort growing I must apply to head quarters for information. One variety of four sets has a smooth and shining leaf; the lower and first-formed leaves being rounded like an Ashleaf Kidney, but of much lighter colour; whereas the other variety of five sets has longer, darker, and more corrugated leaves, which are shaded off from a light centre at the shoot, while none of the lower leaves are so round as an Ashleaf. Which is the true Excelsior? It may be stated that these Potatoes were supplied by a firm of high standing.—N.

EXHIBITION ROSES.

MR. GEORGE PAUL's catalogue is divided into three parts: the first part contains a list of Roses suitable for exhibition, the second of Roses suited for garden decoration, and the third part consists of new Roses, Teas, and Noisettes.

Now this is a very useful division, as is evident when we remember how many cultivators of the queen of flowers regard it as principally an exhibition flower, while a still larger number care not the least for exhibitions, but wish to have their gardens full of free-blooming and good growing sorts of fair form and colour, while they pay great attention to the fragrance of the various varieties. Of course this division is a help to young beginners who wish to go in for exhibiting, but at the same time it is not strictly and solely to be relied on, and must not be too closely followed. There are an immense number of Roses in the first division which, while not unworthy altogether of their position, would in my opinion be best relegated to the second division, and every year I notice that some old favourites are thus reduced in position, notably *Comtesse Cécile de Chabrillant*. This old variety has perfect form, but so rarely has sufficient size for a prize stand that Mr. Paul, while no doubt fully recognising its value as a Rose for all other purposes, hardly deems it worthy of a place in his select list. But I would humbly offer my opinion to him and others that the list as it at present stands is far too large and requires much revision. There are so many which I may call duplicates that had far better not be in it. Take, for example, these three Roses, all good in their way, but all so much alike that you might often cut three blooms from the

same tree and show them in the same stand under the names of Exposition de Brie, Ferdinand de Lesseps, Maurice Bernardin. Of these I suppose it will be granted that the one first named is the best, but a tyro reading the catalogue would see there those Roses spoken highly of, and would think it necessary (if he desired to be an exhibitor) to buy them all; and as he will find it necessary to have at the very least twenty of each sort, he will be spending three pounds where one would be sufficient.

Then take another instance. Mdlle. Eugénie Verdier has long held the foremost rank among light Roses, when of late years another Rose almost identical in form, entirely so in colour and wood, is sent out and retains her position as an exhibition flower. This Rose (Mdlle. Marie Finger) only differs from the former by not being quite so globular in form—that is, taking Eugénie Verdier at her very best, but an average Rose of this variety cannot be distinguished from Marie Finger. It is, of course, greatly to the advantage of the nurseryman that these Roses should continue to hold their position in the lists, because in a stand of seventy-two they are most valuable. In one row Eugénie Verdier makes a most delightful contrast in the midst of crimson and dark Roses, while Mdlle. Marie Finger fills the same good office in another part. But amateurs should be warned by someone against purchasing duplicates, unless they wish the Roses to perform the same good office for themselves.

Now as to exhibition Roses, if I were to give a list in this paper I should merely have to copy out the list I sent in at the Rose election, and it would be a little wearisome to read over a long list of names, which any one can easily do by purchasing the number of the Rose Journal that contains the lists. All that I can do in this letter is to give the names of some superexcellent Roses which must be cultivated by exhibitors.

First, then, let me say something about Roses recently introduced by our great English nurserymen. I believe never was the Rose world so rich with English-raised Roses as now. Take first Mr. George Paul's Marchioness of Exeter, Dr. Hooker, Empress of India, Sultan of Zanzibar, Wilson Saunders, and Duke of Connaught. All these are splendid Roses. Then next look at Mr. Turner's list:—Royal Standard, a grand Rose, having perfect form and good colour; Miss Hassard, Oxonian, Rev. John B. M. Camm, and others which I have not proved. Mr. Cant has not done much with seedlings yet, but he has lately brought out one good one called Prince Arthur. This is rather like the Duke of Edinburgh in colour, and resembles in form Général Jacqueminot, and I think it will prove to be a valuable Rose. I saw a splendid bloom of it in Mr. Cant's nursery. Mr. Cranston has sent out one good Rose—Sir Garnet Wolseley, but I do not know of any more except some climbing Roses; but all these English-raised Roses are worth growing, and no exhibitor should long be without them.

Concerning older Roses fit for exhibition, much, very much, can be written, and the only question is where to begin and where to leave off.

Amateurs are never called upon to show more than forty-eight, and this is almost too large a number for anyone but giants like Hercules and Mr. Jowitt. To show this number, however, calculating, too, upon there being eight Teas in the stands, an amateur should cultivate about sixty sorts; for some varieties of Roses bloom far too late in the year to be of use for most of the shows, such as Emilie Hausburgh, while others are completely over for the later shows, as Mons. Noman, Abel Grand, &c., so that it is necessary to have double the number of sorts in cultivation to what you are called upon to exhibit.

Of white Hybrid Perpetuals the best undoubtedly is Marquise de Mortemart, but this is such an exceedingly shy bloomer and such a weak grower that you can scarcely ever depend upon it. The next best is Madame Lacharme, then Boule de Neige, Madame Noman, and Reine Blanche; but the last two I do not grow.

Of blush Roses undoubtedly Madame Rothschild is the best, then Marguerite de St. Amand, Duchesse de Vallombrosa, Madame Vidot, and La François; of this last I know nothing from experience, as I do not grow it, but it was shown very fine at the Crystal Palace.

Of the next shade in colour (rosy blush) La France is the best, then Eugénie Verdier, Abel Grand, and now and then Captain Christy will give a fine bloom, but I do not recommend anyone to grow it.

Of pink and rose-coloured Roses Marquise de Castellane, Mons. Noman, Mdlle. Marie Cointet, and Emilie Hausburgh. Among crimson and cherises stand pre-eminent Marie Baumann, Alfred Colomb, Dupuy-Jamain, Beauty of Waltham, Madame Victor Verdier, Dr. Andry, and a host of others.

Of the darker varieties Charles Lefebvre still holds his own, but is close pressed by Lord Macaulay, Horace Vernet, Ferdinand de Lesseps, and many more; while of the very dark Roses Xavier Olibo (a wretched grower), Louis Van Houtte (ditto), Duke of Wellington, Prince Camille de Rohan, and Fisher Holmes must all be cultivated.

I have endeavoured to class the very best sorts according to their colours, and I hope that the above will be useful to some few of your readers, and who may wish next autumn to buy some of the very best Roses. It would be wearisome to your readers to name all the sorts, even if you had space, so those only are named which are the best examples of their class, according, that is, to the best of the belief of a—WYLD SAVAGE.

ALEXANDRA PALACE ROSE SHOW.

JUNE 30TH.

SEVERAL days of fine weather, a fortunate fixture, and a liberal schedule combined to render the Exhibition a good one. Indeed, considering the unfavourable Rose season—winter almost entirely overlapping spring, and summer coming in with a bound—the display may be described as excellent. That it would be equal to the last Rose Show that was held in the large concert hall of the Palace could not have been expected, for that Exhibition was the best that was held during a much better "Rose year" than this is. On Saturday there were some rather wide gaps in the four long tables in the body of the hall and the two side tables when the blooms were judged; but by regularly distributing the boxes the blanks were not greatly "felt." The concert room is a capital place for a Rose show, its subdued light showing the colours of the blooms to advantage, and preventing them also rapidly expanding. A little more light on Saturday would, however, have been an improvement. It was an enjoyable Show and well arranged, and Mr. McKenzie and his assistants left nothing wanting on their part to render the day a pleasant one to all. The Show was crowded with visitors during the afternoon.

The nurserymen exhibitors took a distinct lead both in the size of their blooms and the quality of them. Some amateurs undoubtedly exhibited well, notably Messrs. Baker, Jowitt, and Camm, but the majority were not in "good form." The brothers Gayter, the renowned "growers" for Messrs. George Paul and Turner (and than whom few are more competent to speak on the matter), do not regard the present as a good "amateurs' year," as only maiden plants can be relied on for splendid blooms, and of those plants there is obviously not the same choice in private as there is in trade collections.

The first and the principal class was for nurserymen, seventy-two varieties, single trusses. There were five competitors, four of whom were awarded prizes. Messrs. George Paul & Son, Cheshunt, were placed first; Mr. Cant, Colchester, second; Mr. Keynes, Salisbury, third; and Messrs. Cranston & Mayos, Hereford, fourth. The Cheshunt blooms were unquestionably the finest. Amongst them we noticed François Michelin, grand, certainly the premier bloom of the Show; Centifolia rosea in the true Cheshunt style; Mons. E. Y. Teas, a fine example of a promising Rose; Margaret Brassac, like a perfect Charles Lefebvre; Miss Hassard and Madame Lacharme, good; Emily Laxton, a lovely bloom, with wonderful foliage; Wilson Saunders, rich and full; Duchesse de Vallombrosa, excellent, as also were Marquise de Castellane, Jean Liabaud, Sénateur Vaisse, Marquise de Ligneris, Princess Beatrice, Charles Lefebvre, Felix Genero, Maréchal Niel, Baron de Bonstetten, Abel Carrière, La Rosière, Thomas Mills, Fisher Holmes, and the Duke and Duchess of Edinburgh—a collection of great weight and quality. Mr. Cant staged very fresh medium-sized blooms with good foliage. Madame Lacharme was perfectly lovely, as also was Souvenir d'Elise, Devonensis, Madame Willermoz, and Mdlle. Marie Finger; and in extremely fine condition were Madame Annie Wood, very bright; Louis Van Houtte, splendid; Sir Garnet Wolseley, Duchesse de Vallombrosa, Star of Waltham, Prince Arthur, very bright; and Xavier Olibo. This collection was rightly placed second, although it was closely run by Mr. Keynes's excellent contribution. Many of the blooms in the Salisbury stands were very perfect. François Michelin was again pre-eminent, Etienne Levet the finest bloom of that fine variety in the Show; Beauty of Waltham, Duchesse de Vallombrosa, Mons. E. Y. Teas, good again; Louis Van Houtte, excellent; Felix Genero, Mdlle. Eugénie Verdier, Madame Lacharme, and La Rosière were all in fine condition. The best Teas, and good they were, were Madame Bonnaire, Souvenir d'Elise, Marie Van Houtte, Madame Sertot, Niphotos, and Devonensis. Messrs. Cranston & Mayos' collection was also a capital one.

Etienne Levet, Comtesse d'Oxford, and La France were splendidly shown.

In the class for forty-eight varieties, three trusses of each, there were five competitors, and the prizes were awarded as follows:—First, Messrs. G. Paul & Son; second, Mr. Turner, Slough; and third Mr. Keynes. Messrs. Paul's were the largest blooms, a few being flat and inclined to coarseness; but the majority of the triplets were good, notably Emily Laxton, Madame Lacharme, fine; Mons. E. Y. Teas, splendid; as also was François Michelin. Excellent were La France, Marguerite de St. Amand, Edouard Morren, Cheshunt Hybrid, Maurice Bernardin, Exposition de Brie, Duchesse de Vallombrosa, Mlle. Marie Cointet, Nardy Frères, Etienne Levet, Marquise de Castellane, Ferdinand de Lesseps, Julie Touvais, Annie Laxton (admirable), Mad. Prosper Langier, Beauty of Waltham, Mlle. Marie Finger, and Victor Verdier. Mr. Turner staged blooms a trifle smaller, but remarkably fresh and of undeniably excellent quality. Maréchal Niel, Sir Garnet Wolseley, François Louvat, Mons. E. Y. Teas, fine; Mrs. Baker, excellent; Marie Baumann, splendid; Baron de Bonstetten, large and rich. Madame Lacharme, Princess Beatrice, Etienne Levet, and Exposition de Brie were all in excellent form. Mr. Keynes also staged an extremely good collection.

In the class for twenty-four varieties, Hybrid Perpetuals (trebles), Mr. Cant won premier honours with a beautifully fresh and good collection. Madame Lacharme was very perfect, and not less so were Abel Grand, Maurice Bernardin, Victor Verdier, Ferdinand de Lesseps, Beauty of Waltham, Etienne Levet, Marie Baumann, and Mons. Noman. Marquise de Mortemart was conspicuous in this collection. Mr. Turner was second with medium-sized blooms, very regular and very fresh. One of the most striking triplets in the stand was La Rosière. Oxonian, Madame Lacharme, Etienne Levet, and La France were very perfect; and very good were Victor Verdier, Charles Lefebvre, Baronne de Rothschild, and Madame E. Verdier—an admirable collection. Messrs. G. Paul & Son staged a capital collection and secured the third place. Mr. Keynes was awarded a fourth prize for large and excellent blooms, which had they been judged an hour earlier would have had a higher position.

In the class for twenty-four varieties, single trusses, there were six competitors. Mr. Turner was a clear winner, his blooms being of good size, yet perfectly fresh and in excellent colour. Maréchal Niel, Madame Lacharme, Mrs. Baker, and Comtesse d'Oxford were splendid. Mr. Keynes was placed second with larger blooms, but some lacking freshness; but these were not Madame Lacharme, Felix Genero, Etienne Levet, Mons. E. Y. Teas, and François Michelin, which were almost perfect. The third prize went to Messrs. Cranston and Mayos. Reynolds Hole in this collection was very rich. Mr. Cant had the fourth prize.

Twelve Tea-scented and Noisette Roses.—In this class there were four competitors. Messrs. J. Mitchell & Sons, Piltown Nurseries, Uckfield, were placed first with a really charming collection. The blooms were stout, smooth, and fresh; just three-quarters open, when Teas are so attractive. The varieties were Souvenir d'un Ami, Souvenir d'Elise Vardon, Maréchal Niel, Boidron, Moire, Madame Margottin, Madame Willermoz, Catherine Mermet, Souvenir de Paul Neron, Comtesse Ovaroff, Marie Van Houtte, and Jean Pernet. Messrs. G. Paul & Son were second with rather larger blooms, some fully too much expanded. Rêve d'Or was grand, and excellent were Narcisse and Cheshunt Hybrid. Mr. Keynes had the third prize, and an extra prize was awarded to Mr. Turner. The Teas, both in this and the amateurs' class, were much and deservedly admired by the visitors.

We now come to the amateurs' classes. For forty-eight varieties, single trusses, there were eight competitors. R. N. G. Baker, Esq., Heavitree, Devon, had the premier place with wonderfully fresh and beautiful blooms and splendid foliage. It is difficult to note the best when all were good, and not necessary to do so since it would be a repetition of those named in the nurserymen's classes. The Teas, however—Marie Van Houtte, Madame Caroline Kuster, Catherine Mermet, Madame Bravy, Madame Margottin must not be passed in silence. Mr. T. Jowitt, the Old Weir, Hereford, was placed second with a collection of nearly equal excellence. It is not too much to say that some judges would have placed it first. Freshness, however, turned the scale in Mr. Baker's favour, and we think rightly, for while some of Mr. Jowitt's blooms were undoubtedly grand, others were past their best. Rev. T. H. Gould, The Vicarage, Mortimer, Berks, was placed third. Prince Arthur in this stand was splendid, and many others were good, but many bore the marks of inclement weather; and Mr. Joseph Davis, Wilton, Wilts, was fourth.

For thirty-six varieties, single trusses, there were seven competitors, Mr. R. N. G. Baker being again in the foremost place. The best bloom in the stand was La France; but very attractive were Mlle. Eugénie Verdier, Ferdinand de Lesseps, Camille Bernardin, Marquise de Castellane, John Hopper, and Madame Caroline Kuster, lovely. Mr. J. L. Curtis, Chatteris, Cambridge-

shire, was second with generally larger blooms. The most noticeable were Marie Van Houtte, Maréchal Niel, La France, Mons. Noman, Belle Lyonnaise, Triomphe de Rennes, and François Louvat—a capital collection. Mr. Davis, The Square, Salisbury, Wilts, was third. This stand contained many excellent blooms; in fact, the three prize collections in this class were of nearly equal merit. A fourth prize was worthily awarded to Mr. Hollingworth, Turkey Court, Midsstone, for large but fully too much expanded blooms. Mr. Harrington, gardener to E. Mitchell, Esq., Gerpens, Corbetstay, Essex; and Mr. Chard exhibited well in this class.

In the amateurs' class for twenty-four trebles the prizes were awarded as follows:—First, Rev. J. B. M. Camm; second, Mr. Baker; third, Mr. J. Davis; and fourth, Mr. Hollingworth. There were eight competitors. Mr. Camm's collection was decidedly the best. The dark varieties—Horace Vernet, Prince Arthur, Maurice Bernardin, and Xavier Olibo were particularly fine. Mr. Baker's blooms were rather irregular but very fresh; and Mr. Hollingworth's were generally too much expanded.

For twenty-four varieties, single trusses, there were seven competitors. Mr. Smallbones, Chatteris, Cambridgeshire, was placed first with excellent examples of La France, Maréchal Niel, and other popular varieties. Mr. Atkinson, Brentwood, was second with a fresh, excellent, and well-staged collection. Mr. Mayo, Oxford, was third; and Mr. Wakeley, Sittingbourne, fourth.

Twelve Roses, single trusses. The prizes were awarded as follows:—First, Mr. J. H. Pemberton, The Round House, Romford; second, Mr. John Wakeley; third, Mr. J. Tranter, Upper Assenden, Henley-on-Thames; fourth, Mr. H. Atkinson, Brentwood. Mr. J. T. Smallbones and Mr. A. Evans, Marston, near Oxford, receiving extra prizes. Mr. Pemberton staged charmingly fresh and perfect blooms of Madame Lacharme, Prince de Portia, Edouard Morren, Duke of Edinburgh, Maréchal Niel, Sénateur Vaisse, Baronne de Rothschild, Charles Lefebvre, and Belle Lyonnaise. Mr. Wakeley's blooms were also good, and Mr. Tranter staged the best bloom of Maréchal Niel in the Show. It was an excellent class, with thirteen competitors.

In the amateurs' class for twelve Tea-scented and Noisette Roses, single trusses, the prizes went—first to Mr. J. H. Pemberton, second to Mr. C. Davis, third to Mr. J. Hollingworth, fourth to Rev. J. B. M. Camm; Mr. J. W. Chard and Mr. R. N. G. Baker receiving extra prizes. The best blooms in Mr. Pemberton's stand were Madame Bravy, splendid; Catherine Mermet Rubens, Alba rosea, and Belle Lyonnaise. In Mr. Davis's stand Marie Van Houtte, Perle des Jardins, Rubens, Caroline Kuster, and Bongère were in excellent condition. Mr. Hollingworth's blooms were small but very lovely, and Mr. Camm's had been rather shaken in transit.

The following were open classes:—For twelve Roses of 1875, 1876, or 1877, Mr. Turner won with the following varieties in grand condition:—Madame F. Janin, Duchesse de Vallombrosa, Col. de Sansal, Royal Standard, Jean Liabaud, Miss Hassard, Mrs. Baker, Rev. J. B. M. Camm, Oxonian, Dean of Windsor, Star of Waltham, and Mons. Fournier. Messrs. G. Paul & Son were second with Star of Waltham, Emily Verdier, Miss Hassard, Madame Prosper Langier, Marguerite Brassac, Emily Laxton, Madame F. Janin, Marchioness of Exeter, Oxonian, Jean Liabaud, Duchesse de Vallombrosa, and Sir Garnet Wolseley. Some of the blooms were rather too much expanded. Mr. Keynes was placed third in this class, and Mr. Piper, Uckfield, fourth with nearly the same varieties as those above named, the exceptions being Marquis of Salisbury, Peach Blossom, Miss Poole, Beauty of Waltham, Reynolds Hole, and Cheshunt Hybrid.

For six trusses of any Rose of 1875, 1876, or 1877 Messrs. G. Paul & Son were first with Emily Laxton in admirable condition—a medium-sized but fine Rose. Mr. Turner was second with Miss Hassard, also a fine Rose; Mr. Cant third with Duchesse de Vallombrosa, rather small; and G. Paul & Son fourth with Marchioness of Exeter, fine full blooms.

In the class for eighteen English-raised Roses in commerce Messrs. George Paul & Son won with Emily Laxton, Bessie Johnson, Cheshunt Hybrid, Miss Hassard, John Hopper, Edouard Morren, Princess Beatrice, Annie Laxton, Princess Mary of Cambridge, Duke of Edinburgh, Miss Poole, Beauty of Waltham, Rev. J. B. M. Camm, Miss Ingram, Star of Waltham, Duchess of Edinburgh, Reynolds Hole, and Marchioness of Exeter. Edouard Morren, however, is a French and not an English-raised Rose. Mr. Charles Turner had the second prize.

In the open class—twelve Roses, single blooms, distinct—there were six competitors. Mr. Cant was first with charmingly fresh blooms of Devonians, Exposition de Brie, Abel Grand, Général Jacqueminot, Souvenir d'Elise, François Michelin, Baronne de Rothschild, Marguerite de St. Amand, Marie Baumann, Louis Van Houtte, Marquise de Mortemart, Madame Charles Wood, and Marie Van Houtte. Mr. Turner was second, and Mr. Smallbones third with capital collections.

For twelve trusses of Hybrid Perpetual Duke of Edinburgh Messrs. Paul & Son were the only exhibitors, and had the first

prize; for twelve trusses of Hybrid Perpetual Baroness Rothschild Messrs. Paul & Son were first and Mr. Harrington second; for twelve trusses of Hybrid Perpetual La France Messrs. G. Paul & Son were again first, and Messrs. Cranston & Co. second; for twelve trusses of Hybrid Perpetual Marie Baumann Mr. B. R. Cant was first, and Mr. R. N. G. Baker second for fine blooms; for twelve trusses of Noisette Maréchal Niel Mr. Charles Turner was first with very rich blooms, and Mr. Davis second; for twelve trusses of Hybrid Perpetual Princess Beatrice Mr. B. R. Cant was first, and Messrs. Paul & Son second; for twelve trusses of Hybrid Perpetual Edouard Morren Messrs. G. Paul and Son were first, and Messrs. Mitchell & Sons second for splendid blooms; and for twelve trusses of Hybrid Perpetual Madame Lacharme Mr. B. R. Cant was first, and Mr. Charles Turner second for excellent stands. For one vase of Roses, cut blooms, set up with Rose foliage only, the prizes went in the following order:—First to Mr. Charles Turner; second to Mr. J. Gardiner, Southgate; and third to Mr. J. W. Chard. In the miscellaneous class an extra prize was awarded to Messrs. William Paul & Son for an extensive and fine collection of Roses, also to Mr. C. Turner for a splendid collection of Pinks. A certificate of merit was also awarded to Mr. Charles Turner for Dean of Windsor Rose.

THE NATIONAL ROSE SOCIETY'S EXHIBITION AT ST. JAMES'S HALL.

JULY 4TH.

WHAT a contrast to the dull dreary day on which in December last some thirty or forty lovers of the Rose met together at the Horticultural Club to inaugurate the formation of a Society which should have for its special object the queen of flowers, the national flower of England, the flower that poets have sung of and lovers delighted in. Then all was expectancy, now all is a reality fulfilled. There has been no discontent, and so we must alter one word and say—

"Now is the winter of our expectation
Made glorious summer."

We know not what may be the result financially; but when the Society can muster some 250 members, when we can tell of more than 400 entries, which means 10,000 blooms, when we can say that from all points of the compass the very *crème de la crème* of English Rose-growers both professional and amateur have gathered together to the high festival, we may surely say that the Rose deserves the name of queen not merely from her own intrinsic beauty, but from the wide allegiance and the loyal homage that she claims—aye, and obtains too. But why at St. James's Hall? Is that a fitting casket for such a jewel? Is that a place where the Rose can be seen in perfection? Well, some can remember the first Rose show held there nineteen years ago and fancy another has not been seen to excel it, and now, as then, the desire was to bring the show into the heart of London. Those public places which are in the hands of companies were deemed unsuitable; Kensington and the Regent's Park were both considered too far off for the purpose; no open space could be secured, and if it could have been then all would have depended on weather; whereas in a room at any rate there is security from many of the annoyances which a wet day in a tent entails; and hence the discomfort of crowding and of being obliged to place some Roses where they could not be seen to perfection had to be endured in order to secure a central position. St. James's Hall appears, therefore, to have been a matter of necessity rather than of choice for holding the Show.

It will readily be believed that the office of Secretary has been no light one, but we are assured that it has been made much less heavy by hearty, cordial, and kindly co-operation which has been afforded, also by the confidence all have expressed, and especially, perhaps, by the hearty assistance of many local secretaries, some of whom have contributed very much to the success of the Society by their strenuous efforts on its behalf, and which have resulted in this great Show, for it may be said without reservation that no such gathering of Roses and Rose-growers has ever met in merry England before to do honour to our national flower. We have no wars of the Roses now; a friendly tournament is all we claim to hold, and we only look for it that the best knight may win his spurs and acknowledge the high honour he has obtained. Those honours were such as to be worthy of the best efforts of our best rosarians, and when such are engaged in earnest and kindly rivalry, why, then the Rose reigns triumphant. Rose weather, too, has at length prevailed, but it was not until almost the very eve of the Show. True we had brilliant days in June, but the ground and the air were dry and the blooms did not grow in a free, fresh, natural manner, but were, as was somewhat forcibly remarked by a real Rose-worker, "pulled out." But with July came a change: on the very first day of the month—the Rose month—a splendid shower fell over a wide district of the southern counties. On the

second day a partially clouded sky promoted a moist genial atmosphere; on the third sunshine mingled with shower, and induced a free unfolding of the blooms; and on the fourth, the memorable fourth, was the tournament—the feast.

The Rose was indeed in royal session yesterday, but they were southern beauties, the date being quite too early for the north, even for the north midland counties, where a few straggling blooms, the advance guard of the Rose army, are only now just forming. The morning of the Show was dull with the barometer slightly falling, but the day proved fine.

Unfettered by harsh laws Rose admirers—her lovers, the hard-working cultivators, came and offered freely of their very best at her shrine. What a theme this is for a poet to sing of!—a Rose show held in the very centre of London, in a hall large enough for all ordinary gatherings, but inadequate in every way to the needs of rosarians; and yet all we can say of it to-day is but a few hurried words—the leading incidents of the Show. Whether, then, we regard the number of exhibitors, the nature of their exhibits, or the general appearance of the Hall, we must pronounce the Show of the National Rose Society to have been what all lovers of the Rose will rejoice to hear—a great success. Mons. Cochet, the proprietor of the French *Journal des Roses*, who attended the Show, was surprised at its excellence, and stated that they have no Roses in France which can at all be compared with the grand English-grown blooms.

In describing the Exhibition we cannot do better than follow the order of the schedule, which commences as usual with the nurserymen's classes.

Class 1, seventy-two distinct, single trusses. The prizes were £12, £9, £5, and £3, and when it is considered that six great nurserymen competed it will be seen that there were plenty of good Roses to look at. In this class Messrs. G. Paul & Son and Mr. Cant ran very close. Mr. Cant's stands were placed in a very bad light close to the entrance door, but the Judges took the trouble to have them brought into a good light when making their awards. Mr. Paul was first with a very even and good stand. Mr. Cant's collection contained a considerable number of Teas. He had a lovely bloom of La Boule d'Or, the only one in the class; but the best bloom in his stand was Souvenir d'Elise. This was simply perfection; very large, with beautiful colour, and of superb form. Mr. Cant also had a fine bloom of Niphetos, which usually comes so fluffy and open; but here it may be said that Mr. Keynes showed by far the best Niphetos in the Exhibition. Devoniensis, Anna Olivier, and Souvenir d'un Ami were all to be found in grand form in his stands. The Colchester Hybrid Perpetuals were very fine, but the best were Mrs. Veitch, Etienne Levet, and François Louvat. This latter is seldom seen at shows, except in Mr. Cant's stands, and rarely grown by amateurs. This only shows how old varieties are often discarded as being useless now that newer and supposed finer novelties take their place in the rosery, and many such Roses as François Louvat ought to be grown as largely as Duke of Edinburgh and Charles LeFebvre. Mr. Cant had also fine blooms of Duchesse de Vallombrosa. The importance of a new good light variety of the colour of Baronne de Rothschild and the form of Madame Vidot in a stand consisting for the most part of crimson and high-coloured varieties cannot be overestimated. Another comparative novelty which he showed a magnificent bloom of was Mr. Cranston's Rose Sir Garnet Wolseley. If that hero was present yesterday he must have thought that this Rose was even worthy of his name and renown. Among our old favourites Mr. Cant showed magnificent specimens of Mlle. Marie Rady, Sénéateur Vaisse, Olivier Delhomme, Xavier Olibo, Marie Baumann, Charles Lefebvre, and (wonderful to relate) Gloire de Vitry. Once more that gem of the first water, that pure snow white Lily among the Roses, Madame Lacharme, came to the front. On the maiden she appears this year to be perfect. Mr. Cant's blooms are mentioned first, not because he was first, for Mr. Paul rightly won the premier prize, but the Colchester Roses were so fresh and attractive. To Mr. George Paul, however, belongs the honour of winning the premier prize at the premier show of the year, and no words can do justice to the regularity, the form, and the general excellence of the blooms; wonderfully fresh they were and of great substance. His stands, too, were full of novelties. Among these was a very good bloom of John Bright, a variety which will take a foremost place in the catalogues and the garden. But without further criticism the whole of the seventy-two varieties may be named which won him this great honour. They were Madame Charles Wood, Mlle. Marie Finger, Auguste Rigotard, Duchesse de Vallombrosa, Victor Verdier, Mons. E. Y. Teas, Peach Blossom, John Bright, Catherine Mermet, Maurice Bernardin, La France, Camille Bernardin, Mad. Vidot, Ferdinand Janin, Annie Laxton, Duke of Edinburgh, Mons. Noman, Felix Genero, Mrs. Baker, Elie Morel, Sénéateur Vaisse, Marquise de Gibot, Etienne Levet, Duchesse de Morny, Henri Ledechaux, Capitaine Christy, Mrs. G. Paul, Lælia, Robert Marnock, Madame Lacharme, Horace Vernet, Baronne de Rothschild, Louis Van Houtte, Maréchal Niel, Comtesse d'Oxford, Paul Verdier, Le Havre, Madame Nachury, Marguerite Brasseac, Edouard Morren, Ferdinand de Lesseps, Mons. Boncenne, Marquise de Ligneris,

Duchesse de Caylus, Clotilde Rolland, Xavier Olibo, Centifolia rosea, Alfred Colomb, Duchess of Edinburgh, Exposition de Brie, Princess Beatrice, Marie Baumann, La Ville de St. Denis, Jean Liabaud, Niphetos, Miss Ingram, Lord Macaulay, Olivier Delhomme, Marchioness of Exeter, Antoine Ducher, Marquise de Castellane, C. Lefebvre, Abel Grand, Annie Wood, Star of Waltham, Madame H. Jamain, Mdlle. Marie Cointet, Dr. Andry, and François Michelin. Messrs. Cranston & Co. were placed third with a good and level collection, and Mr. Keynes fourth with large blooms.

Class 2, forty-eight Roses distinct, three trusses of each. The prizes were £10, £7, £4, and £2, and they were awarded in the following order:—First to Messrs. Cranston & Co., second to Mr. Cant, third to Mr. Turner, Slough, and fourth to Mr. Keynes. The winning stands undoubtedly contained the largest blooms, and many of them were very perfect, but the Colchester and Slough Roses were the freshest. A few grand trebles in the first-prize stand were François Michelin, Madame Lacharme, Antoine Ducher, Etienne Levet, Le Rhone, Duchesse de Vallombrosa, Madame Vidot, Beauty of Waltham, Mdlle. Jacquier, Princess Beatrice, La France, Baron de Bonstetten, Mdlle. Marie Cointet, and Dupuy-Jamain.

Class 3, forty-eight Roses, distinct, single trusses. The following were the exhibitors:—Mr. Turner; Mr. J. Bunyard, Ashford, Kent; Messrs. Cranston & Co.; Mr. J. Keynes; Messrs. J. Mitchell & Sons, Uckfield; Mr. Cant, and Mr. Prince; and the prizes went—first to Messrs. G. Paul & Son, second to Mr. Turner, third to Mr. Keynes, and fourth to Messrs. Cranston and Co. The winning stands contained massive and highly coloured blooms. Especially striking were François Michelin, Henri Ledechaux, Xavier Olibo, Madame Charles Wood, Exposition de Brie, Louis Van Houtte, Comtesse d'Oxford, Mons. E. Y. Teas, Abel Grand, Duchesse de Vallombrosa, Victor Verdier, Mdlle. Eugénie Verdier, Marchioness of Exeter, and Madame Lacharme. Mr. Turner had Annie Laxton, Miss Hassard, François Michelin, and Maréchal Niel, grand; Mrs. Baker, Victor Verdier, Royal Standard, Devonensis, Belle Lyonnaise, François Louvat, Madame Lacharme were in charming condition, and the rest good. The other collections while containing many splendid blooms were yet somewhat irregular.

In the class for twenty-four trebles Mr. Cranston was first with very good trebles of even size and fresh bright colour. Mr. Paul was second, Mr. Cant third, and Mr. Turner fourth.

In Class 5, for twenty-four Hybrid Perpetuals, Mr. Curtis came to the front with a lovely stand, as fresh as if the blooms had not travelled a mile—as fine as if they had been cut from a quarter of a million of maidens. The most noted blooms were Prince Camille de Rohan, Duke of Edinburgh, Marguerite de St. Amand, Victor Verdier, La France, Marie Baumann, Mons. E. Y. Teas, and Black Prince, the last-named being equal to any Rose in the stand.

And now let a "WYLD SAVAGE" speak of his own particular pets—the cream of the Roses, the choicest of flowers, the loveliest of Nature's gifts. No less than eight nurserymen staged twelve Teas and Noisettes, and most charming work it was to judge them and discuss their beauties with two other enthusiastic rosarians. Mr. Cant was pre-eminent here on his own ground, tilting with his own particular lance, doing honour to his queen with the weapons of which he best of all others knows how to employ. What a stand it was! Here was La Boule d'Or again, which no other man in England can show so well, Souvenir d'Elise, Devonensis, Marie Van Houtte, and all the other leading sorts. This class was fortunate enough to have one of the best places in the Hall assigned to it, and so the visitors could see these jewels under every favourable condition.

Mr. Mitchell of Piltown came second with varieties some of which were quite equal to Mr. Cant's; but he did not show here nearly so fine as he did at the Crystal Palace. He showed a Rose, however, which is rarely seen—Duc de Magenta, and if the illustrious namesake only pleases the general public in France half as much as his Rose will please the public here, he need be in no doubt as to the result of the general election. The third prize was won by Mr. Davison of Hereford with a most uneven lot. He had a magnificent bloom of that coy pet Comtesse de Nadailac, and one or two other blooms were good, but the rest were poor. Mr. Keynes just secured fourth honours by the beauty of one bloom. This was Niphetos before alluded to. The other exhibitors had many fine blooms in their stands, but there was nothing striking or worthy of notice.

AMATEURS.—A vast number of blooms—the cream of the amateur growers—were exhibited. Hercules came from fair Devon with his marvellous blooms, so bright in colour, so lovely in form, and so fresh; Mr. Jowitt came from Hereford with blooms which can only be called magnificent; that great rosarian, the father of Rose shows, the President of this Society and the originator of the one of which this is no mean descendant, came from Causton with blooms of splendid size, freshness, and colour; and Mr. Arkwright, Hampton Court, Herefordshire, Mr. Pochin, Mr. Hollingworth of Maidstone, and a host of others came to swell the number.

In the class for forty-eight distinct, single trusses, there were fourteen entries. In this class Messrs. Cranston & Co. offered a fifty-guinea challenge cup for the first prize. This cup must be won in three years, and the winners in 1877 and 1878 can be the only competitors for it in 1879. First Mr. J. Jowitt, The Old Weir, near Hereford, who thus wins the first chance for this great trophy with Alfred Colomb, François Michelin, Madame C. Crapet, Madame Baronne de Rothschild, Duke of Edinburgh, Lord Herbert, Général Jacqueminot, Dupuy-Jamain, Prince Camille de Rohan, Louis Van Houtte, Dr. Andry, Xavier Olibo, Mdlle. Marie Rady, Exposition de Brie, Madame Marie Finger, Alfred Colomb, Lælia, Madame Boutin, Madame Hippolyte Jamain, Maréchal Niel, Louisa Wood, Monsieur Noman, Cheshunt Hybrid, Edouard Morren, Annie Laxton, Duchess of Edinburgh, Sir Garnet Wolseley, Madame Bellon, Capitaine Christy, a seedling, Monsieur Boncenne, Camille Bernardin, Madame Nachury, Marie Baumann, Clemence Joigneaux, Marguerite de St. Amand, Prince Arthur, Mdlle. Marie Cointet, Souvenir d'un Ami, Marie Van Houtte, L'Esmeralda, Jules Margottin, Princess Mary of Cambridge, Devonensis, La France, Ferdinand de Lesseps, and Annie Wood. Too much praise cannot be awarded to Mr. Jowitt, who won the cup. His blooms were really marvellous considering the distance he had come, and the fact that a thunderstorm raged at Hereford on Tuesday. Mr. R. N. G. Baker, Heavitree, Exeter, was second with a charming and very fresh collection. He had grand blooms of Alfred Colomb, François Michelin, Marie Baumann, Duke of Edinburgh, Duke of Wellington, Ferdinand de Lesseps, Maurice Bernardin, and others, running Mr. Jowitt very close. The Rev. Canon Hole, Causton Manor, Newark, was placed third; and the Rev. J. B. M. Camm, Monckton Wyld, Charmouth, fourth.

For thirty-six distinct, single trusses, there were seventeen entries. Mr. R. N. G. Baker was awarded the first prize; Mr. J. Brown, Reigate, second; the Rev. E. N. Pochin, Barkby Vicarage, Leicester, third; and the Rev. J. B. M. Camm fourth. Mr. Baker's collection was composed of Victor Verdier, Maurice Bernardin, Mdlle. Marie Rady, Charles Lefebvre, Mdlle. Eugénie Verdier, Fisher Holmes, Royal Standard, Marie Baumann, Baronne de Rothschild, Exposition de Brie, Marquise de Castellane, Duke of Wellington, Baron de Bonstetten, Auguste Rigotard, Comtesse d'Oxford, Xavier Olibo, Marquise de Mortemart, Alfred Colomb, Souvenir d'un Ami, Lord Macaulay, Marguerite de St. Amand, Camille Bernardin, Prince Camille de Rohan, Miss Hassard, Etienne Levet, Ferdinand de Lesseps, Madame Charles Wood, Pierre Notting, Madame Victor Verdier, La France, Louis Van Houtte, Marquise de Gibot, Sir Garnet Wolseley, Monsieur Noman, and Dr. Andry.

In the class for twenty-four, distinct, Hybrid Perpetuals, there were eighteen competitors. Mr. Atkinson, Brentwood, Essex, was placed first with a very fresh, good, and even collection, consisting of Madame Clemence Joigneaux, Marquise de Castellane, Duke of Edinburgh, Baronne de Rothschild, Louis Van Houtte, Edouard Morren, Charles Lefebvre, Marguerite de St. Amand, Dr. Andry, Anna de Diesbach, Dupuy-Jamain, Duchess d'Aoste, Camille Bernardin, Monsieur Noman, Marie Baumann, Madame Barriot, John Hopper, La France, Fisher Holmes, Henri Ledechaux, Duke of Wellington, Comtesse d'Oxford, François Michelin, and Jules Margottin. Mr. R. N. G. Baker was second, Mr. Jowitt third, and the Rev. E. N. Pochin fourth.

Twenty-eight competitors entered the class for twelve single trusses, distinct, the first prize being a silver cup value five guineas, presented by the proprietors of the *Journal of Horticulture*. In this class were to be found some of the finest blooms in the amateurs' section of the Show. Mr. J. Smallbones, Chatteris, Cambridgeshire, won the cup with very fine blooms of Dupuy-Jamain, La France, Etienne Levet, Mdlle. Marie Rady, Camille Bernardin, Baronne de Rothschild, Monsieur Noman, Prince Camille de Rohan, Abel Grand, Duke of Edinburgh, Marquise de Castellane, and Louis Van Houtte. Mr. Pemberton, Havering, was placed second; Mr. D. Sewell third; and Mr. H. Bensted, Rockton, Maidstone, and the Rev. W. H. Benn, Churchover Rectory, were equal fourth. In the class for six single trusses there were twenty-two entries. The first prize was awarded to Mr. J. Lakin, Chipping Norton, Oxon, for La France, Madame Victor Verdier, Jules Margottin, Maréchal Niel, Marquise de Castellane, and Souvenir d'un Ami; the second prize to Mr. A. Evans, Marston, near Oxford; third to Mr. J. Smallbones; and fourth to Mr. E. L. Fellows, Wimple Rectory, Royston.

In the amateurs' class for twelve Tea or Noisette Roses there were about twenty competitors, Mr. J. Brown, Reigate, being the fortunate winner of the first prize—a silver cup, value five guineas, presented by E. Mawley, Esq.—with Belle Lyonnaise, Souvenir d'Elise, Devonensis, Niphetos, Alba Rosea, Souvenir d'un Ami, Cheshunt Hybrid, Rubens, Marie Van Houtte, Anna Olivier, Madame Willermoz, and Maréchal Niel. Mr. J. Chard, Clarendon Park, Salisbury, was second; Professor Adams, The Observatory, Cambridge, third; and Mr. W. Smith, Birch Hall, Colchester, fourth. The whole of the collections were very beautiful.

OPEN CLASSES.—In Class 14, for twelve new Roses, distinct, single trusses, which have been in commerce since 1874, some very fine stands were shown. Mr. Turner here won the premier prize with blooms of great size, good colour and form. I (says "WILD SAVAGE") only noticed three bad blooms in the lot. A bloom of Mrs. Baker (Madame Hercules) in this stand was even worthy of that lady. I do not remember to have seen this Rose attain such form before; but if once a-year or once in two years one could get such a bloom it would be worth while to grow the Rose. He also had a marvellously good bloom of Mr. Cant's seedling Prince Arthur, also Mr. Paul's Rose Duke of Connaught; Duchesse de Vallombrosa and Madame Prosper Langier were both good. His own seedlings, John Stuart Mill and Royal Standard, were shown fine; while Mr. William Paul's Rose Star of Waltham outshone even its name and rivalled the brightness of the sun. Mr. George Paul was second with a good and even lot of blooms, the best of which was Mons. E. Y. Teas. Many of the above-named varieties were also in his stand, which was quite up to the average of new Rose exhibits. Mr. Curtis of Torquay came third: he staged a grand bloom of Sir Garnet Wolseley; and Lady Mary Keith and Royal Standard were also very fine.

For twelve trusses of English-raised Roses Messrs. G. Paul and Son won premier honours with Emily Laxton, Cheshunt Hybrid, Dr. Hooker, Rev. J. B. M. Camm, Reynolds Hole, John Hopper, Marchioness of Exeter, Star of Waltham, Duke of Edinburgh, Annie Laxton, Duke of Connaught, and Beauty of Waltham. Mr. Turner was placed second, and Mr. Cant third; and in the class for any new seedling Rose Messrs. G. Paul and Son were placed first for John Bright, which was in brilliant condition, and Mr. Turner second with Penelope Mayo, a grand new Rose resembling Marie Baumann, but having greater substance of petal.

For twelve blooms of La France there were six competitors. Mr. R. N. G. Baker won with grand examples; Professor Adams, The Observatory, Cambridge, was second with smaller but fresh blooms; and Messrs. G. Paul & Son third. For twelve blooms of Marie Baumann, Mr. Cant was first, splendid; Messrs. G. Paul & Son second; and Mr. Prince third. For twelve blooms of Alfred Colomb Messrs. G. Paul and Son had the first place; and Messrs. Laing & Co., Forest Hill, the second, for excellent stands. For twelve of Maréchal Niel Mr. J. H. Arkwright, Hampton Court, Leominster, had the premier place with grand and richly-coloured blooms. Mr. Turner, Slough, was placed second; and the Rev. W. H. Benn, Churchover Rectory, third. For Baronne de Rothschild the prizes went to Mr. Baker for grand blooms; Mr. J. Scrubby, Rundles, Harlow, Essex; and Mr. Cant in the order named. For twelve blooms of Louis Van Houtte Mr. Cant was first, very rich; and Mr. Baker second. The only prizewinners that we could find in the class for twelve blooms of Reynolds Hole were Messrs. G. Paul and Son; and for twelve blooms of Fisher Holmes Mr. Baker won the prize offered by that firm with fine examples of a Rose which is by no means easy to grow and show well.

For twelve trusses of any Rose not included in the above "twelves" Messrs. Curtis & Sandford, Devon Nurseries, Torquay, won with magnificent blooms of François Michelin, Messrs. George Paul & Son were placed second with the same variety, and Mr. Turner third with Mille Marie Cointet.

To Mr. Camm we are indebted for valuable assistance, and his words may fittingly close this report. They are as follows:—"We have done our task. Handicapped as to time, judging, staging in four classes, hurried in every way, it has been no easy matter to make even these few and imperfect notes; but such as they are they are given in the hope that they may at least not do dishonour to one of the grandest shows of Roses in the memory of Rose-growers. If a pleasant gathering, the making of new friends, and the fresh uniting of old acquaintances; if lovely blooms, happy and friendly faces, beautiful weather, can make a show successful and pleasant, then the first Rose Show of the National Rose Society will prove to be one of the brightest days that ever dawned on Rose-growers, and the only regret that we shall feel is that it is over, and that another year must elapse before we have such an opportunity of doing honour and paying our court to the queen of flowers."

A ROSE WITH A STRONG PEACH SCENT.

On an east wall of the garden I have a Rose now laden with flowers having a full strong perfume precisely like that of a Peach. Although thin, and loose, and scant of petals, they are not unornamental, the incurved petals being arranged in that pleasing cup-like order which is so much liked. It was received under the name of President, and its colour of mingled rose and salmon answers to the description of that variety in the catalogues. The growth is long, somewhat slender, with very few thorns, and foliage of medium size.

Upon a west wall there is another tree received from another nursery as Victor Pulliat, but which is precisely similar to the

one named President on the east wall, the Peach-like scent of the flowers leaving no doubt that they are identical. As Victor Pulliat is described as white tinged with yellow, I conclude that both my plants are President; and I am curious to know if other growers of it have detected its peculiar and certainly not unpleasant perfume.—EDWARD LUCKHURST.

NOTES AND GLEANINGS.

We have received from Mr. W. G. Smith a photograph of the portrait of the distinguished fungologist and physiologist Rev. M. J. BERKELEY, which has been suspended in the lecture hall of the Royal Horticultural Society at South Kensington. It is an admirable likeness, and we cannot suggest a better souvenir of one who lives in the affections of so many people than the excellent portrait which Mr. Smith has taken.

—THE NEWCASTLE SUMMER SHOW will be held on the 12th and 13th inst., and not on the 13th and 14th, as stated in our last issue.

—We are informed that a BOTANICAL FETE AND MUSICAL PROMENADE will be held in the Pine Apple Nursery Grounds, Maida Vale, by permission of Messrs. E. G. Henderson and Sons, on Thursday evening, July 12th, 1877, in aid of the fund for the enlargement and improvement of St. Mark's Church, Hamilton Terrace, N.W. The conservatory will be illuminated with gas and coloured lights, and embellished with works of art; and a large marquee will be erected, in which there will be a handsome display of flowers, epergnes, table decorations, and works of art. The fete is under the patronage of his Grace the Duke of Westminster, K.G., the Most Noble the Marquis of Hertford, Lord Garvagh, Rev. Lord Theobald Butler, Sir Henry Thompson, Col. Du Cane, R.E., C.B., and other distinguished ladies and gentlemen.

—MESSRS. CARTER & Co. have made arrangements with the Royal Botanic Society that their SHOW OF ANNUALS shall extend to July 12th, instead of the 3rd, as previously announced.

—MR. W. T. F. M. INGALL, Greenhithe, writes to us as follows on the USE OF PETROLEUM in the garden:—"Our sowing of Beet was looking very well, but it suddenly gave signs of going off, when my gardener directly sprinkled the crop with soot and then watered it with petroleum and water (in the use of which he is getting very apt). The crop quickly recovered, and has been doing well ever since."

—IN alluding to MANURE FOR ROSES Mr. Camm writes, "Let me thank with all my heart your correspondent 'J. B. K.' who has given me such valuable advice as to artificial manures. I will certainly try his mixture next year, and will let you know the results."

—THE annual Exhibition of the WEST KENT HORTICULTURAL SOCIETY is announced to be held in Bickley Park on Saturday next, the 7th inst. The schedule is of the same comprehensive character as heretofore, and the Exhibition is expected to equal former displays which have been provided by the Society.

—It is impossible to over-estimate the USES OF GLASS, yet it was accidentally discovered by some lumps of soda being used to support a pot over a fire on the seashore. The heat of the fire caused the soda and sand to unite, and their union formed rough glass.

—It has been estimated that the State of California has 15,000,000 acres of land adapted to the growth of the VINE, but that less than 50,000 acres of this vast area are as yet planted. The average number of Vines set out per acre is about nine hundred, which gives an average yield of 800 gallons of wine and 120 of brandy when in full bearing. The progressive advance of the industry is shown by the fact that the number of gallons made in 1859 was 100,000; in 1869, 500,000; in 1872, 3,000,000; in 1875, 7,000,000; in 1876, 10,000,000. If the present year be a favourable one for the Grape crop a yield of 11,000,000 to 12,000,000 gallons, worth \$4,000,000, may be expected.

—"M. J. B." states that Pooley's TOBACCO POWDER is the best thing he has ever tried for cleansing trees from green fly. "A Peach tree in one of our houses was in bad health last year. Shortly after the leaves began to expand this season they became covered with green fly. Syringing with various thoroughly recommended mixtures had no effect on them, because the leaves were so curled that the remedy could not reach the insects. At last the tree was dusted all over with Pooley's powder and gently syringed daily, but not enough to wash the powder

off, only sufficient to work it down into the curled leaves. In a week after this was done not a fly was alive on the tree, and the luxuriant growth it has now made would lead anyone to suppose there had not been a fly on it this season."

— THE PHORMIUM TENAX, or New Zealand Flax, is, it is said, being largely planted in St. Helena on behalf of a fibre company, who propose so to plant all the Government waste lands in the island.

— CONSIDERING the great beauty of the ERICAS it is a little surprising that they are not more extensively grown. Some of the most handsome and healthy specimens that we have seen of late are in the rising collection at Cleveland House, where one sometimes hears it said that Mr. Legg does nothing else besides carpet bedding. The Heaths in his charge, however, are in splendid condition, rivalling in health the more commanding fine-foliaged plants. Some of the ERICAS which were exhibited at the early shows are now flowering for the second time this season as freely as ever; and an idea may be formed of their vigour when it is stated that such sorts as Jubana rubra and Victoria have as many as twenty flowers on a truss. Candolleana, Dennisoniana, and the true obbata are extremely beautiful; and equally so are some of Messrs. Rolleston's new varieties, which are seldom seen. Mr. Ralli perhaps possesses the finest plant of E. Shannoni glabra extant; it is extremely beautiful, and the more valuable because the rosy white flowers are not gummy but are as smooth as glass. In fine contrast is E. oppulenta, rich crimson lake, the flowers lasting a month in beauty. Another richly coloured variety is E. effusa, crimson. E. ornata is a charming light-coloured variety; and E. tricolor profusa is both distinct and attractive. These are garden hybrids, and will prove to be greenhouse plants of the very first order of merit—varieties if well grown which cannot disappoint.

— PARIS GREEN is admitted to be the best specific in destroying the Colorado Potato beetle, and has also been used against the Phylloxera and garden pests generally. An American paper says no doubt exists as to its efficacy in destroying insects; but it must also be remembered that it is a metallic poison, composed of arsenic, copper, and acetic acid, containing about half its weight of arsenic in a semi-soluble form. It is dangerous to inhale, and poultry, hogs, sheep, and even dogs should be kept away from the fields in which it is used. Great care should be taken in using it.

ROSES, &c., AT THE REV. W. F. RADCLYFFE'S, OKEFORD FITZPAINE.

Now that Roses are so coming to the front, and the National Society's Show is so close upon us, a brief record of a short and pleasant visit to a garden which ought to be dear to all Rose-growers may not be unacceptable. It was hurried, but I could not manage it otherwise; but there was much to talk about and much to see.

It is now some three or four years since I saw my dear and valued old friend; and although time has dealt somewhat sharply with him, and severe illness has deprived him of some of his wonted activity, it has no way checked his love for Roses or made him take a less earnest interest in his garden; and I have never seen it in better order, although failure has resulted in some of his crops owing to the desperate weather we have experienced this spring—weather to which his garden has been specially exposed, for the terrible westerly wind sweeps over the downs and on to the village. So great was its force that it swept in a few minutes the entire Ivy covering of the viarage garden, and tore the coverings of the Peach trees to tatters; while severe frost had tried his Rose trees, at a time too, when he was laid by and unable to attend to them; so that there had been much to contend with. But my friend is not to be deterred by difficulties, and I need not say as far as possible all has been remedied.

As I have frequently said, the persons who will be most likely to be interested in visiting this garden will be the real lovers of Roses: the exhibitors, the mere searchers for novelties, or those who look for prettiness, will be disappointed. My friend never exhibits; he buys no new Roses. When one is well established in favour he tries it; and his object is to have his Roses safely moored, and so tall stakes are prominent in his garden. And when he finds a Rose to suit his soil and situation then he goes in for a quantity. Let me name, then, a few of those which I saw in superb order. Charles Lefebvre was grand in all stages of development. Talking the other

day at Spalding about Roses, a very distinguished amateur said that he never saw it now with that beautiful dark shading that it used to have. Had he been with me he might have seen it to his heart's content—enormous blooms with the most splendid colouring. Then I do not think I ever saw Princess Mary of Cambridge so fine: it was large, larger than I ever recollect seeing it, and the colour so soft and beautiful. When I speak of size it must be remembered that my friend never disbuds a Rose. He cut me off some blooms of Jules Margottin of immense size with four or five buds around it. And so with all his Roses. M. Clémence Joigneaux, John Hopper, Baronne de Maynard, Camille de Rohan, Lord Macaulay, Madame Victor Verrier, and such-like were by the score, for when he finds that a Rose suits his soil and situation he goes in for it largely. He will probably add fifty of Princess Mary of Cambridge because it has done so well; and so it will be with others. Then another object he has in view in his pruning is to keep up a continuous bloom, so that his secateur is constantly at work, and he thereby gets good strong shoots for autumn blooming.

There are three Roses about which his judgment has been much questioned—Madame Chirard, Baron Chaurand, and Felix Genero. With regard to the first he has been obliged to alter his opinion. The Rose is large and the growth of it most vigorous, but it fails in opening, and consequently he has felt it necessary to place it in the background. With regard to the other two I do not wonder at his liking them. Baron Chaurand, though not an exhibition Rose, is undoubtedly one of the most brilliant-coloured flowers we have, intense fiery scarlet in the centre—unlike any Rose I know; and certainly Felix Genero as grown here needs no comment. It is lovely both in form and colour, while in size it is no way behind the greater number of our exhibition Roses. There were blooms of it here which might have gone into any stand. Another Rose almost gone out of cultivation, but certainly worthy of a place for its intense colour, and a great favourite here, is Souvenir de Dr. Jamain. It is a small neat Rose, but of the most beautifully deep claret colour possible; never large enough to be in a stand, but certainly to be desired by all who love variety in their Rose garden. Duke of Edinburgh was here very brilliant in colour, similar to those I have seen in Hercules' garden at Exeter; and what Rose can be more beautiful when caught in its true scarlet hue? Time and space would fail me in enumerating the beauties I saw here, but enough will have been said to show that my good friend has not abated his zeal, and that his hand has not lost its cunning.

The Peach and Nectarine trees were in marvellous health and beauty; no blistered leaves, but large and well-developed foliage, showing that with care and attention even in a locality so little favourable they can be grown without disease. But of fruit, as in every place that I have seen this year, there was next to none. This is a matter which no skill can secure, and indeed in many orchard houses there is the same report as on the outdoor walls. But Mr. Radclyffe may well be proud of his trees. I have seen many a large garden this year where the trees afford a very unfavourable contrast to those I have seen here.

And then with all his other cultures what glorious rows of Lapstones are here! a Potato my good friend clings to in spite of all the highly trumpeted novelties both from across the water and at home. And well he may, for at his hospitable table there was a dish of them as mealy and as good as in the very height of the season, and this when new Potatoes were being used. At least it was Yorkshire Hero, which after several years of cultivation I must pronounce to be the same thing. A little later it may be, but I do not think the graft which it was supposed to arise from had been much influenced by the stock, or *vice versa*.

The same high-class cultivation went through everything, Peas and all other vegetables grown here; but the one flower was the Rose. It is with the Rose that the name of Mr. Radclyffe will be always associated; and when some of our English growers raise a Rose worthy of a good name, as they have already done, let them honour themselves by affixing to it that of a true rosarian and a thoroughly kind and hearty old English gentleman, for my dear friend has now reached the allotted threescore years and ten. Simple in his habits and patriarchal in his ways, his chief delight is to benefit those around him. No case of real sorrow but what his heart and hand are open to, while he is beloved by those immediately about him. One inevitably thinks of Sir Roger de Coverley in his presence; for while he lacks the stiffness of that fine portrait he has all

the *bonhomme*, the generosity and kindness, that characterised Addison's ideal. One never leaves him without the feeling that few are like him; and I feel confident that those who may differ from him in judgment, as sometimes they may do, did they know him would feel that it could only be done with the deference due to one who with large experience has also a real and hearty love for the pursuit we alike love.—D., Deal.

VINES IN POTS AT WORCESTER.

WHAT becomes of all the Vines which are grown in many of the nursery establishments? is a question one often hears asked. It is a very natural question, especially when we remember that with ordinary care and good management the Vine may be kept to do good service for many years. One of the largest growers of young Vines in England is Mr. Richard Smith. In his nursery at St. John's, Worcester, about three thousand young Vines were grown last year, but this year a still larger number is being prepared, and not only are they large in number but excellent in quality. Even at this early period and under the very cloudy and cold unfavourable season some hundreds of good canes are fast ripening their wood, so much so that the first lot of Vines are already placed outdoors with canes as thick as one's finger. Here they can finish-off their ripening while the heat of summer is at its best.

Some growers of Vines have no objection under some conditions to plant young Vines for permanent growth in the middle of summer: hence it is that some are often being sent out from this establishment throughout the growing season as well as during the dormant period of the Vine. It is well worth a journey to any person much interested in the culture and growth of young Vines to pay a visit to this nursery. Free growth and short joints, with well-ripened wood, are the chief points to be attended to in Vine cultivation; and on these points excellent lessons are derivable at the principal nurseries where Vines are largely cultivated.—GEO. DAWSON.

TORQUAY ROSE CLUB.

"ANOTHER Rose show! Another account of excellent Roses, superb blooms, perfect forms, &c., by that wildest of Wyld Savages too!" may perhaps be the remarks made by some gentle readers of our Journal as they turn over your Rose number and see the whole of the excellent Journal for one week at least devoted to Roses.

Yes, and why not? What can be better, what can be more delightful than a Rose show? The more shows the merrier, say we; the further afield we go with our boxes the jollier for us. The more the superiority of the Rose above all other flowers is evinced by the number of times which she finds her worshippers eager to pay her court by tilting lances in her honour, why, the better. And here this year the Queen of the West—the most famous of all watering places both as a winter resort and as a summer residence, the home of yachting men—the portly town of Torquay, invites us to come and show our blooms and do our best in honour of *Rosa regina florum*. We accept the invitation; we cheerfully undergo no end of fatigue in order to show there, and also to get back home in time to stage for the Alexandra. Ah me! that Alexandra! Would that they would not always fix on a Saturday for their shows. If the Directors would for one moment reflect how many persons are exhibitors, and how hard it is in country places to get one's duty done, they would, I think, in charity change the day. The Crystal Palace Directors are too old at their work, too hard-hearted men for us to hope to move them; but the Alexandra people surely have tender hearts and kind dispositions, or else they are scarcely worthy of the name by which their place is called. So may even a "WYLD SAVAGE" plead for a change next year? This year I must miss the Show, and what such a loss is to me all rosarians know.

After the Show at Exeter the Torquay cannot be pronounced to be a first-class Show, for in the first place there was literally no competition for the head classes. Mr. Cranston had the misfortune to lose a box, which entirely destroyed his chance, as he was unable to stage the required seventy-two. So there was no one against Mr. Curtis except an amateur of the name of Robson, who ventured to compete in a class which for the very largest amateur growers it would be folly to attempt; as it was, his seventy-two contained duplicates, which disqualified it. Roses were wrongly named, and altogether a more miserable stand it has never been my lot to judge. Messrs. Lucombe & Pince put in also an appearance, staging a box of twenty-four blooms of Niphetos, and in one of the smaller classes for Hybrid Perpetuals.

The amateurs were in great force. Mr. Baker led the van, and

well sustained his great reputation by winning first prizes in the three classes in which he staged. Mr. T. Jowitt of Hereford maintained his grand form, securing two firsts; and Mr. Beachey and Mr. Tomlinson also took first prizes. Mr. Jowitt showed the best eighteen I think I ever saw, or at least it would be indeed a sight to see anything finer than seventeen of the blooms. The eighteenth was certainly unworthy of its position, and Mr. Jowitt recognised this by not naming it. He had blooms of Madame Rothschild, Marquise de Mortemart, which I never saw surpassed. The latter was the purest white, with what I may call the rare Centifolia form (for this Rose I mean). The centre was suffused with most delicate shades of rosy flesh. Aurora arising from the sea could not have been more lovely, and I do not think some rosarians will soon forget the bloom. He had also a lovely bloom of a variety, which I never saw before, called Julie Duran. This in colour is between Ferdinand de Lesseps and Antoine Ducher, but in form it is pure globular, each petal winding round the other like a lovely bloom of Madame Bravy. He had also fine blooms of Louisa Wood, Hippolyte Jamin, and others. I have spoken at length about this stand, as with the exception of the Teas his stand was the finest in the Exhibition.

Mr. Baker's forty-eight, considering that he is not yet in anything like full bloom, was very fine. As usual his blooms were distinguished by their bright fresh colours and their lovely form; of course, in a stand of forty-eight in a hot tent it would be impossible for some not to be a little overblown, but these when judged were very few. He was of course, as usual, exceptionally strong in the highly bright-coloured varieties. His Marie Baumann, Xavier Olibo, and above all Charles Lefebvre were splendid. It is really a great treat to linger over his stands when one has the opportunity and compare his blooms with what we know we have left in our own gardens, and be spurred thereby to still greater efforts to grow Roses well. I had the honour of being placed second to him in forty-eights and in Teas. Concerning this class they were the finest I have seen this year. Mr. Charles Turner said he did not remember to have seen so many or so good before. Mr. Baker showed the same bloom of Marie Van Houtte which he exhibited at Exeter, and though a little fuller it was as fresh and good as ever. He also had Caroline Kuster, Madame Willermoz, and Madame Margottin exceedingly good. The only bad bloom in his box was Maréchal Niel. He also had some very fine trebles, and secured here of course first honours.

The Torquay Show will be ever memorable to me from a bloom shown by Mr. Curtis of Prince Camille de Rohan. It is impossible to describe either the form or colour. It would be almost as rash on my part as to try and paint the Lily, but it is not too much to say that no finer bloom of that dark variety can ever have been shown. He had also a box of very good new Roses, and again he showed Abel Carrière, the variety I described (or tried to do at least) in my account of the Crystal Palace Show. This bloom was really splendid, in form something like Andry or Lefebvre, but in colour like Camille de Rohan or a very fine Louis Van Houtte. He showed also very finely Souvenir de Arthur Sansal. This I think may be described as an improved Jules Margottin.

Besides Roses there was a fine collection of miscellaneous plants, but it is no part of my duty to describe them; sufficient is it to say that Dr. Woodman brought some of his splendid specimens, which I believe are considered to be the finest in England. Altogether it was a very fair show; and if only in future years the Committee will be a little more liberal in the matter of prizes, and not offer £2 instead of £5 as the second prize for forty-eight varieties, and, if they are otherwise unable to increase their expenditure, will reduce the number of classes and devote the money saved to making the prizes in the remaining classes a little more equivalent to the value of the exhibits, the Torquay Rose Show may one day be one of the events of our Rose year.—WYLD SAVAGE.

AURICULA CULTURE.

I SHOULD like to be clearly understood that I know cocoa-nut fibre is an excellent covering for the drainage in the pot prepared for hospital treatment of this flower, as it retains cavities longer than leaves would, but it must not be used where the roots are allowed to run into it. Again, as to liquid manure I may have been somewhat inexplicit; therefore I would say that the cow dung for that liquid cannot well be too old—two years at least, and must be reduced to dust. Then, as to strength, it is difficult to describe it exactly; perhaps about a quart of the strong liquid to a gallon of soft water, and must not in any case be darker-coloured than ordinary soft water, and may not be used too early in the season. Let the trusses repose down in the heart of the plant till seasonable weather calls them forth. When the truss has given signs of movement give a soaking of the liquid manure, which must be

followed by the ordinary watering. Never store this liquid or it will deceive you. The Polyanthuses in the border will be grateful for it, and you must make fresh again when the first pip begins to expand, and if you wish to take seed another dose when the flower is fading. This last liquid should be made with leaf mould.

In my next communication I will detail an entirely different mode of culture for the Auricula, a method which insures green and white edges from the inconstant varieties in those classes, also very large foliage, yet not soft or flabby; much larger pips, and fine plump seeds, yet the method will be found simple and natural.—G. W. BULLOCK, *Brockton, Stafford.*

PROPAGATING ROSES.

Roses, unlike some other flowers, are in full beauty at the same period, when measures must be taken to increase the stock of plants. The month of July is the month of Roses, and the same month is the month for budding, also for inserting cuttings. Many, I know, will not accept the latter statement as being correct, nevertheless I must repeat that July is the best month for striking cuttings of Roses. Roses are also increased by grafting, but as that is spring work I will not further allude to it in the "Rose week."

I sometimes think that it is because the Rose is in full beauty during the season for budding that so many Rose buds are inserted. People, not rosarians, but just ordinary people, are smitten with the charms of the Rose and are conquered. They impulsively ask how to insert buds and when, and on receiving the necessary information they set to work on the spur of the moment, inserting buds on all sorts of stocks suitable and unsuitable, and become rosarians in embryo before, as the common saying is, "before they know where they are." There would never be so many growers of Roses if budding were not so easily learnt, and if the Roses, the glorious Roses, were not there to "coach" them, impel them, to become proficient in the art. Every year there are beginners in the art of Rose-budding; every year there are numbers who insert their "first bud." They insert it wrongly, possibly for want of knowing better, perhaps insert it as I inserted my first bud—wrong end upwards, and perhaps it may grow as mine did when so inserted. That just proves how accommodating the Rose is, how simple is the process of budding; and when I hear anyone attempting to enshroud the art with a certain amount of mystery, as I sometimes have heard, I always think of my first Rose bud.

In the early days of my Rose career (long years have rolled since then) I had not the advantage of a guide, I had not seen the *Journal of Horticulture*. I had to grope my way as best I could, ashamed (I may as well own it) of asking for information for fear of betraying my own ignorance. It was very weak, I know, on my part, but I never had a strong nerve, and I no more dare append my name to this letter than I dare in the centre of St. James's Hall next Wednesday declare the Rose the most ugly flower of earth. Paradoxical as it may appear, it is because of my diffidence—my weakness, that I write on the subject of budding Roses. There is an old and true saying that an "old poacher makes a good keeper;" he knows the frailties of the craft he has to deal with, their weak points, their habits. Remembering, then, my own early difficulties, and presuming there are others as weak and yet as willing now as I was weak and willing then, I offer them my sympathy, my aid.

I often think, and I have heard others express the same opinion, that there is a powerful vein of sympathy existent between the readers of your *Journal*. If anyone will make his want known on any horticultural matter, however difficult it may be on one hand or simple on the other, there is always someone ready to "turn up" in the most frank and friendly manner. I was much struck a fortnight ago with the difficulty of one of your contributors in obtaining manure for his Roses. He had no manure, he could neither make it nor buy it, and asked how he was to proceed. That was I thought a poser; yet "J. B. K." comes to the rescue, and in a most valuable letter gives more information than I venture to say Mr. Camm bargained for. But I am digressing—am wide of the mark on budding, and I must think of my friends who desire to know how to bud and do not like to ask.

Perehance this number of the *Journal* will reach someone in perplexity at the same opportune moment that a number reached me nearly twenty years ago. It not only told me when to bud, but showed me how to do it. I have always had a great re-

spect for that number, and I think I can repeat the first sentence from memory, although I cannot state the year nor the month when it appeared. My rendering is as follows:—"What is the best weather for budding? I am told damp cloudy weather is." How often would such a question, asked by an amateur, obtain such an answer? How startling, therefore, to him to be informed to the contrary! Why, he has seen it recommended in books! Yes, nothing more generally recommended than damp cloudy weather for budding! To say bright, warm, sunny weather is best, provided the stocks are in proper condition, will sound like heresy; extensive experience, however, tells me such is the case. I may be asked why? and I would answer that in warm weather the sap is more gelatinous; and the bud, on being extracted and inserted in the stock quickly, properly tied, &c., soon takes. On the contrary, in wet cloudy weather the sap is more thin and watery, and the bud will not unite so freely. To this we add that a fall of rain (likely in such weather) after the buds are inserted will fill up the incisions, and thereby rot and perish the buds before they have time to unite with the stocks. Not only is clear warm weather best for the experienced budder, but likewise for the amateur and tyro." [Correct.—Eds.]

The last word I can remember is "tyro." It was that word that riveted my attention. I was indeed a tyro then in Rose budding, and there may be other tyros now. I write, then, for tyros. Close your eyes, rosarians; skip this page, it is not for you, you need different fare, and will doubtless find a spread of it; but remember that you once hungered for different food than that you now require. Well, after reading that article referred to some years elapsed, and other equally clear, perhaps more so, illustrations of the simple matter of Rose-budding appeared. Although I perhaps could then bud as well as the contributors of those articles, I read them as keenly as if I had never inserted a bud. The "old love" was remembered, was rekindled, and glowed as warmly as ever. One of the articles I allude to was signed "T. J. S., *Twickenham*," the other I forget. I cannot give you the dates, nor even guess at them. I'm not good at dates; and I cannot refer to the numbers, for I always send my *Journal* away after perusal, where it is bound and preserved; but it is far from me at the present moment. And now, Messrs. Editors, a happy thought strikes me (I wish it had occurred to me before). If you would turn to the numbers and again submit to your new readers what you once submitted to the "old subs," I am sure you would win their thanks and save my time. The authors in my mind and your library have told how to insert buds better than I can tell it, and I will vouch for it the practice detailed is as good as ever. It has never been improved upon—has never been put so clearly before, and can never be put more clearly again. I flatter myself that a good idea has been born to me, and I shall rely on your carrying it out. If I see anything wrong in it I will correct it next week. In the meantime time has flown freely, and I must be in town to-night (Monday), and shall remain for the National on Wednesday. Perhaps I may call at 171; but do what I ask of you. I'm off.—JOHN HOPPER.

[What can we do but comply? We do so readily, however, because the information requested is good and the *modus operandi* of budding is clearly shown. As our correspondent has also mentioned the striking of Roses from cuttings without detailing the practice we publish what Mr. Luckhurst has written under that head.—Eds.]

"I ascertain," says "T. J. S.," "the time the stocks are ready for budding by rubbing off some of the thorns, and if these are easily detached I know the stocks are in the right condition. I then cut the shoots back, leaving on them three or four buds to the stock. In the shoot to be budded I make a T cut (as shown in fig. 1 at *a*), just through the bark, being careful not to injure either the wood or bark, insert the point of the handle of the budding knife gently into and along each side of the longitudinal cut (fig. 1), detaching the bark from the wood to allow of the insertion of the bud, for which it is now ready. Obtain the bud by choosing one which appears to be the fullest from a branch or shoot of the Rose to be propagated. Cut it off, as shown in fig. 2, take the wood out of it carefully, so as not to pull out the heart of the bud, insert it in the T cut under the bark, fig. 3 (in fig. 4 I have shown a large bud with the wood in *a*, the wood in course of removal at *a*¹, the wood taken out, the heart of the bud being left, and to which the arrow points, at *a*²), push it close up, as in fig. 5, and tie firmly with wool or ball lamp cotton, as in fig. 6. As the original buds in the shoots in which the bud of the required

Rose has been inserted keep pushing I pinch them all off, in order to throw as much vigour as possible into the inserted bud, and am careful that no other shoots grow from the stock. When the inserted buds have grown the length shown in fig. 7 I remove the tie. As I prefer to have blooms as soon as possible I permit the inserted bud to grow as long as it will, and am often rewarded with flowers the same season. In the

following April I cut back this shoot, leaving only on it three or four good buds, as shown in fig. 8."

CUTTINGS.—"At no better time," says Mr. Luckhurst, "can Rose cuttings be made than directly after the first or summer bloom is past. Stout firm wood of the current year's growth, and which has carried a truss of bloom, should be selected for cuttings, which, when made, should not be longer than 6 or

7 inches. This length will admit of two, and in close-jointed wood of three eyes, with a portion of each leaf on the upper

termed a heel as in fig. 9, which represents part of a finished cutting ready for inserting in the soil, fig. 10 showing the branch from which the cutting was taken. This heel is quickly coated over by the callosity, which soon begins to form, and from which the roots readily start."

THE AQUILEGIA.

I do not know whether Aquilegias should be catalogued amongst the neglected plants; but this I do know, that it is many years since I used to admire the fine clumps of *Aquilegia vulgaris* of many colours, including the pure white variety, in the cottagers' gardens in Scotland; but even in country districts the inevitable scarlet *Geraniums* and yellow *Calceolarias* or *Feverfew* have usurped the place of the stately *Columbine*. Collections of herbaceous plants are not complete without the addition of some of the different species of *Aquilegia*, and now that many of the trade growers are forming collections we shall see our old favourites taking the position which their merits deserve.

They are of the easiest culture, and may either be grown in pots or planted out in the open border. I have grown a goodly number of species and varieties, but have found some of them to be rather difficult to manage. I had in the first place a plant or two of each species, but will now only mention those that are easily cultivated and which will be certain to flower

Fig. 9.

Fig. 10.

part of the cutting. A small portion of the old, or last year's wood, must be left at the base of the cutting to form what is

freely every year. The first I will mention is *A. leptocera aurea*, not *A. lutea*, which has been in cultivation a number of years, and is a poor washy-looking flower not worth room in the border. The other sort was introduced some five or six

years ago, and the first flowers of it that were exhibited at South Kensington were from the gardens at Loxford Hall, and to it a first-class certificate was voted by the Floral Committee. I have many plants of it now in flower raised from seeds, and

Fig. 11.—*AQUILEGIA CÆRULEA HYBRIDA*.

all of them are true to name. The flowers are golden yellow, and instead of drooping, as in some of the species, they are nearly upright. The spurs are also deep yellow and about 3 inches in length. I have had plants over 2 feet in height, and bearing quite a hundred charming flowers. The plant is

of very vigorous growth. *A. cærulea* is another very beautiful species. The flowers are large, pale blue, the centre white; they are also erect like the first-named sort. The plant bears numerous flowers on a spike from a foot to 18 inches in height.

A. californica is a desirable variety from the colour of its

flowers, which are scarlet. They are not large, and are borne on straggling branches nearly 3 feet high. It has short spurs. The plant is hardy and easily grown in pots.

A. pyrenaica is a very desirable species. The flowers are purple, drooping, very large, and abundantly produced on slender stems a foot in height. The rich purple flowers afford a pleasing contrast to the pale blue, deep yellow, and scarlet of the other species.

In 1875 I was tempted to hybridise a few of the species, in each case taking parents very distinct in character from each other, and the result has been very satisfactory. Of one variety I flowered this year about 130 plants, and there is scarcely any difference amongst them. One plant had flowers a little larger than the others, but in no other respect did they differ, and they were exactly intermediate between the parents. This variety has as its female parent *A. leptocera aurea*; the pollen was taken from *A. californica*. The flowers are scarlet as in *A. californica*, but the centre is golden, like the variety from which the seed was saved. It has also the long spurs of that variety, and the flowers, though not so large as the female parent, are very much larger than the male. It was named *A. californica hybrida*, and received a first-class certificate from the Royal Horticultural Society, and also a certificate of the highest merit from the Royal Botanic Society.

A. cærulea hybrida, the variety that has been so faithfully delineated in the excellent wood engraving accompanying this article, was raised by crossing *A. leptocera aurea* with *A. cærulea*. The flowers are pale blue and as large as *A. cærulea*; but instead of the white centre, as in that sort, the centre is yellow. The plant also grows taller than *A. cærulea*, but not so tall as its female parent. It also bears a larger number of flowers. As in the case of the other hybrid, all the flowers are alike, and the bunches exhibited both at South Kensington and at the Royal Botanic contained flowers taken from several plants. This variety also received first-class certificates from the Royal Horticultural and Royal Botanic Societies.

No garden should be without these fine flowers. They are excellent border plants, have a fine effect in the greenhouse or conservatory, and are invaluable for cutting to place in vases for the drawing-room or for making-up dinner-table decorations. Even when not in flower their glaucous finely-divided leaves have a pleasing effect. In hot weather red spider attacks the leaves, but not to an injurious extent, and it is easily destroyed by syringing.—J. DOUGLAS.

RICHMOND HORTICULTURAL SOCIETY'S SHOW.—JUNE 28TH.

SUBURBAN horticultural exhibitions have now become numerous, and it must be admitted they are doing much good for the encouragement of horticulture in their immediate neighbourhoods. There are many good horticulturists who cannot conveniently exhibit at the metropolitan shows, but who are none the less hardworking and able cultivators, and it is at these local meetings that they are able to meet in friendly rivalry and test their horticultural abilities with their neighbours.

Richmond Show occupies a high position as a suburban show, situated as it is in a very wealthy and fashionable neighbourhood, where plenty of support is provided of funds and exhibits. It has also a good, practical, working Committee and a Secretary with great zeal and energy. It is, therefore, not surprising that their third annual Exhibition should have proved a good one. The arrangements were ample and excellent, five marquees being set apart for the various entries, which numbered about five hundred. The groups, stove, greenhouse, and plants in general, were staged in the largest tent; cut flowers and dinner-table decorations in a second; fruit and vegetables in the third; the fourth was set apart for all productions responding to the long list of special prizes; and the fifth for cottagers' productions. The weather for the occasion was extremely hot, and the fine old trees surrounding the deer park formed a grateful shelter to the influx of visitors—the rank and fashion of the neighbourhood—from the fierce sun's rays.

The centre of the large tent was devoted to specimen plants, the groups being arranged around the sides with just a few tables at large intervals, on which were placed the hardy Ferns, Orchids, Gloxinias, and Geraniums. Six competitors tried their skill for the groups of plants arranged for effect. These groups, which occupied a space of 100 square feet, were semicircularly arranged on the grass. Mr. Howell, gardener to Sir H. W. Parker, Stawell House, Richmond, was placed first with a very light and effective group. The front edging was composed principally of *Panicum variegatum*, interspersed with small *Pelargoniums*, *Adiantum cuneatum*, and other Ferns, small Palms,

&c., the whole backed-up with larger Palms, Crotons, and such-like plants. Mr. Kinghorn, Richmond, who must have been a very close second, had a very graceful and elegant group of well-grown plants. Messrs. Jackson & Sons were third, but this collection though rich was overcrowded. An extra prize was awarded to Messrs. Hooper & Co., The Nurseries, Twickenham, in this class.

In the open class for nine fine-foliage plants Mr. Kinghorn was placed first with good plants of *Dracæna indivisa*, *Pandanus Veitchii*, *Dicksonia antarctica*, *Chamærops Fortunei*, *Yucca aloifolia variegata*, *Croton Weismanni*, and others. Mr. W. Bates, gardener to W. H. Punchard, Esq., was a good second; and Mr. Cornhill, gardener to J. S. Virtue, Esq., third. Messrs. Jackson and Sons were the only exhibitors in the class for nine stove and greenhouse plants (open), and were deservedly awarded the first prize. Exotic Ferns were well shown, and were a grand feature. In the class for eight plants Mr. D. East, gardener to J. Wigan, Esq., Clare Lawn, East Sheen, staged fine examples of *Dicksonia antarctica*, *Adiantum formosum*, *A. concinnum latum*, *A. cuneatum*, *Asplenium bulbiferum*, *Cibotium Schiedeii*, *Cyathea dealbata*, and *Gleichenia flabellata*, and received the first prize. Mr. Cornhill was placed second; and Mr. Wells, gardener to the Hon. J. Vivian, Selwyn Court, third. The above class, together with three classes for Roses and three for fruit, were open classes, the remainder being limited to subscribers. It will be convenient to first take note of all the Roses, and then the whole of the fruit, whether in the open or other classes.

Roses.—These were shown both in great numbers and of good quality by Messrs. Paul & Son, Cheshunt, and Mr. Turner of Slough. Mr. Paul remarked that he never in his experience staged such a stand of thirty-six trebles. Sultan of Zanzibar, Monsieur Noman, Louis Van Houtte, Abel Grand, Reynolds Hole, Marchioness of Exeter, Madame Thérèse Levet, John Hopper, Cheshunt Hybrid, Mrs. George Paul, Madame Nachury, Camille Bernardin, Marquise de Gibot, Miss Poole, Duke of Edinburgh, Annie Laxton, La Rosière (a fine new dark), Mdlle. Eugénie Verdier, Mons. E. Y. Tess, Victor Verdier, Ferdinand de Lesseps, La France, Horace Vernet, Edouard Morren, François Michelin, Madame Marie Finger, Marguerite de St. Amand, Xavier Olibo, Henri Ledechaux, Elie Morel, Dr. Andry, Etienne Levet, Monsieur Boncenne, and Princess Beatrice were grand, and were deservedly awarded the first prize. Mr. Turner was placed second, in whose stands there were good blooms of François Michelin, Reynolds Hole, Xavier Olibo, Général Jacqueminot, Baronne de Rothschild, and others. Messrs. Dobson and Sons, Isleworth, were placed third. In the class for twenty-four trees (nurserymen) Messrs. Paul & Son were again first. In this collection Mdlle. Marie Cointet was good. Mr. Turner second; Mr. Master, Otlands Park, third; and Messrs. Dobson, fourth.

For twenty-four single trusses (amateurs) there were eight competitors. Captain Eastwick, Teddington, was placed first with large but somewhat rough blooms. Mr. Moorman, gardener to the Misses Christy, Ccombe, second with a very fresh but smaller lot; and Mr. James, gardener to F. Watson, Esq., Isleworth, third. In the class for twenty-four single trusses in the Society's district Mr. James was first, Mr. W. Bates second, and Messrs. Dobson & Sons third. For eighteen and twelve blooms Messrs. Marlow, Smith, and Roberts shared the honours between them; and for the special prizes offered by H. G. Bohn, Esq., Twickenham, Messrs. Marlow, James, and Smith were awarded the prizes in the order named.

FRUIT.—There was a large display of fruit of excellent quality, the best we have witnessed this year. The first-prize collection of six dishes came from Mr. Fry, gardener to L. Baker, Esq., Haydon Hall, Pinner. He had Early Lyons Cherries, Violette Hâtive Peaches, Brown Turkey Figs, Colston Basset Melon, Charlotte Rothschild Pine, and good Black Hamburg Grapes. Mr. Cornhill was second with a very fair lot. Black Grapes were shown by ten exhibitors. Mr. East was placed first, Mr. Bates second, and Mr. Edwards, gardener to the Misses Tristram, third, all showing Black Hamburgs of excellent quality, large in berry, fair-sized bunches, and of an intense black colour. White Grapes were contributed by Mr. Bates, Mr. Edwards, and Mr. Fry, and the prizes were awarded in the order named, Mr. Bates winning the first prize with grand examples of Foster's Seedling. There was also a strong competition for the classes set apart for fruit in Division B, which was confined to the Richmond district, Messrs. Bates, East, Howell, Child, Sallows, Morrell, Lake, Wells, James, and Smith shared the principal honours, and the majority of the productions were very fine.

Orchids were not extensively shown, there being only three competitors, Mr. W. Bates winning first honours with *Oncidium flexuosum*, *Aërides Dayanum*, *Saccolabium retusum*, *Odontoglossum Alexandræ*, *Cattleya Mossiæ*, and others. Messrs. Jackson & Son were placed second, and Mr. Williams, gardener to J. Bridgeman, Esq., Twickenham, third, who all staged excellent examples. Hardy Ferns were shown by Mr. James, Mr. Crafter, and Mr. Morrell, the prizes going in the order named; and exotic Ferns from the Society's district were contributed

by Mr. Smith, gardener to A. Cooper, Esq., Twickenham, who was awarded the first prize. Mr. Morrell, gardener to J. S. Rutter, Esq., Twickenham, was placed second, and Mr. Attrill third. Caladiums were excellently shown; of the five competitors Mr. Morrell was placed first, Mr. Howell second, and Mr. Marlow, gardener to J. Wigan, Esq., third. The prizes for Begonias went respectively to Mr. Sallow, gardener to J. Flack, Esq., Hampton Road; Mr. Wells, and Mr. East.

Pelargoniums, both show and fancy varieties, were well shown by Mr. James and Messrs. Dobson & Sons, the first prize in each case going to Mr. James and the second to Messrs. Dobson. Scarlet, zonal, bronze, and tricolor Geraniums were also very well shown; Messrs. Crafter, Sallow, Wells, Tipping, Smith, and Attrill carrying off the honours. Mr. James was the only exhibitor of six Lilies, and was awarded the first prize. Gloxinias came from Mr. Morrell, Mr. Crafter, and Mr. Smith, who were placed first, second, and third respectively. Coleuses were staged in large numbers, but they had such a weedy look about them when surrounded with other fine-foliaged plants that it would be well to exclude them from the schedule in future. Fuchsias were very well exhibited in the class for nine distinct varieties by Mr. James and Mr. Wells, and in the sixes by Mr. Crafter and Mr. Attrill.

For six stove and greenhouse plants in the Society's district there was a very fair lot, Mr. Crafter being placed first, Mr. Attrill second, and Mr. Goodman, gardener to T. Nesbitt, Esq., Twickenham, third; and for the single specimen plant in flower Mr. W. Bates was placed first for a very fine and well-bloomed *Stephanotis floribunda*, the second prize going to Mr. Attrill for *Rhynchospermum jasmynoides*, and third to Mr. Morrell for *Stephanotis floribunda*.

Dinner-table decorations were not very superior. The best three vases of natural flowers and foliage (open) came from Mr. W. Brown, Richmond, followed by Mr. Kinghorn and Messrs. Dobson & Sons. In the corresponding class for amateurs only, Mrs. A. Chancellor, The Retreat, Richmond, was placed first; Mrs. Moran, St. Margaret's, second; and Miss Augusta M. Warde third. For a single stand Miss Isabella Warde, Mrs. A. Chancellor, and Miss Blanche Lockwood received the awards in the order named. Bouquets came from Mr. Brown, Messrs. Dobson and Sons, and Mr. Kinghorn, who were placed first, second, and third respectively. Button-hole bouquets were very pretty, and Miss L. Gossett, Mortlake, was placed first; Miss Headley, Petersham, second; and Miss J. Warde third.

VEGETABLES.—There was a very fair show of these. The special prize cup offered by Messrs. James Carter & Co., valued five guineas, was won by Mr. Crafter, gardener to the Rev. W. Finch, Kingston Hill; and a good collection of ten sorts came from Mr. Wagstaff, gardener to T. H. Elam, Esq., Firstleigh, Isleworth. There were several cottagers' productions, but for a district like Richmond they ought to have been seen in larger numbers. Their productions on the whole were very creditable.

Extra prizes were awarded to Messrs. Veitch & Sons for a collection of new and rare plants, Roses, &c.; to Messrs. Rollison, Osborn, Dean, and Herbst for miscellaneous collections; and a certificate was awarded to Messrs. Paul & Son for Rose Duke of Teck, a deeper-petalled Duke of Edinburgh.

RICHARDIA ÆTHIOPICA AS A HARDY AQUATIC PLANT.

Few plants have become more popular during recent years than this "Trumpet Lily" of the Cape, as it is popularly but erroneously called. It is not a Lily at all, but an Aroid. It is better known by the name of Calla or Arum Plant than *Richardia*. Callas, however, belong to the natural order of Arontaceæ.

The true name of the plant is *Richardia*. It was introduced from the Cape of Good Hope in 1731, and was named after L. C. Richard, a French botanist. It is a greenhouse herbaceous perennial, and is increased by suckers or division of the plant in spring. For a length of time the *Richardia* was grown entirely in the greenhouse, occasionally having a place in a tank or cistern, where it grew luxuriantly and by chance flowered. It is only during recent years that a systematic mode of culture has been adopted, and plants have been produced which flower with certainty even in a very small state, thousands being annually sold in the London market in 5 or 6-inch pots, each plant having one or more distinct spathes or flowers. At one time it was considered necessary to grow the plants under glass, keeping them dry in the autumn to induce their flowering, but a simpler and easier mode of culture now prevails.

After the danger from frost has passed the *Richardias* are divided and planted in manured trenches in the open ground. They are supplied with water during the summer, and in the autumn are potted. They do not make luxuriant growth

during the hot months of summer, but are sturdy and produce small stout leaves. Like *Celery* they grow the most rapidly when heavy autumn dews prevail. They are potted before the frost injures them, and are placed in light houses. They are introduced into gentle heat as required, and commence flowering at Christmas, and continue throughout the winter and spring months, and during that period they are very valuable for many decorative purposes.

But while *Richardias* are valuable for conservatory and room decoration they are amenable to another—a simpler, easier, but not less effective mode of culture, which cannot fail to render them additionally popular. I allude to them as hardy aquatic plants. For the beautifying of ornamental water, ponds, &c., in pleasure grounds, a "great feature" is anticipated for *Richardias*. They have not yet been largely employed for the purpose named, but that they are well adapted for it a pond almost full of them in Mr. Seely's grounds at Furzedown testifies. Mr. Laing, the gardener, saw them thus growing in Ireland, and concluded that the bottom of a pond in Ireland was not warmer than the bottom of a pond in England, hence he attached weights to the roots of some plants and threw them into the pond to "take their chance." It was a lucky throw, for they grew and have continued growing and flowering for six years. The clumps have from six to twelve flowers on them. The foliage is about a foot above the surface of the water, and the flowers are a foot or more above the foliage. They are very pure, stout in texture, and produce a beautiful effect.

Mr. Rogers, the able Superintendent at Battersea Park, who is always well in the van of floral embellishment, has the *Richardia* growing and flowering in one of the miniature lakes there, and it is greatly and deservedly admired by visitors.

There can be little if any doubt that the *Richardia* will grow and flower in any sheltered pond in England (except perhaps in the northern districts, and is worthy of being tried even there), provided the water is not less than a foot in depth, so as to preserve the crown of the plant from frost, and provided also the water is not too deep; but what the maximum depth is I am unable to say. At Furzedown the plants are established from 1 to, I think, 2 and 3 feet deep.

Throw the plants into ponds now, affixing the roots in the mud, having the principal leaves above the surface of the water and await the results.—J. W.

[We shall be glad if the experiment suggested can be tried in various parts of the country, and to be acquainted with the results.—Eds.]

VITALITY OF SEEDS.

"Some thirty years or more ago my gardener raised about 2 square yards of sods near the road in the park, not far from the small ruin; the ground was left red—not sown with grass seeds. A very thick crop of *Hyoscyamus niger* sprung up. They were cut down when the seeds were formed, and were given to one of the apothecaries of the town. Since then they have not reappeared anywhere until the present year, when I find three plants in full flower near the park road, opposite to the first quarry, where you can see them among some Nettles. *Hyoscyamus* is a common plant in England, but is certainly very rare in this district; in fact, I do not think that I have ever seen a plant of it growing wild with us. The new plants are at about 300 yards distance from the old crop. As the deer will not touch them, there could have been no growth of *Hyoscyamus* plants during the period I have mentioned.—N."

I have offered the only solution which appears to me probable, if possible—viz., that the seeds of *H. niger* lay dormant there for perhaps centuries, until the removal of the sods allowed them to vegetate, bringing them within reach of solar and other influences. The castle—a fine old ruin, which had some hard knocks in Oliver Cromwell's time—most likely had its herbarium "garden of herbs," for medicinal as well as culinary uses, and *Hyoscyamus niger* may have flourished there in the collection; as our poet says—

"Where once a garden smiled,
There still may many a garden flower grow wild."

But would such seeds retain vitality for so many years? The park has been under pasture longer than any one can remember, and the present proprietor is over seventy-five years of age.—H. N. O., Mallow.

[Your suggestion we think is correct. Many seeds if kept quite dormant will vegetate after the lapse of many years. It is chiefly the want of a due supply of oxygen that forbids seeds

germinating which are buried at great depths; seeds thus deposited, or similarly excluded from the air in the Egyptian mummy cements, will often retain their vegetative power for an apparently unlimited time. Hence, earth taken from far below the surface will often become covered with Charlock. This is an oleaginuous-seeded plant; and such, when thus excluded from the air, retain their vitality most pertinaciously for reasons already assigned.—Eds.]

KINGSTON AND SURBITON HORTICULTURAL SOCIETY'S SHOW.—JUNE 27TH.

At The Cranes, Surbiton, this Society held its thirteenth annual Show on the 27th inst., which was an excellent one; indeed not much inferior to the metropolitan shows. The schedule comprised ninety classes, besides a long list of special prizes. The exhibits were arranged in four marquees. Stove and greenhouse plants were extensively shown, and formed a grand feature in the largest tent; and the ladies' tent was particularly attractive from the many admirably arranged examples of dinner-table decorations. Dinner-table decorations are done better and are always shown in larger numbers at Kingston than at many local shows, and a good judge of the metropolitan shows remarked that they were vastly superior to anything to be met with in London. An arrangement of three decorations set up by Miss Eyfe, and composed of only wild flowers and grasses, was exquisitely beautiful, so light and graceful—a most pleasing arrangement, and not, as might be imagined, having a weedy appearance. Other successful exhibitors were Miss Cavell, Misses Gould, Mrs. Clay, and Mrs. Wilson.

Four classes were set apart for stove and greenhouse plants, which brought together a grand lot. In the class for nine plants there were only two exhibitors—Mr. Watson, gardener to T. R. Bryant, Esq., Glencairn, Surbiton; and Mr. Ellis, gardener to J. Galsworthy, Esq., Kingston Hill, who were placed first and second respectively. But the class for six plants brought together six collections, all remarkably well-grown plants. Mr. Hinnell, gardener to F. Davis, Esq., Angelsea House, Surbiton, was first; Mr. Croxford, gardener to Mrs. Dunnage, Surbiton, was second; Mr. Crafter, gardener to the Rev. J. Finch, third; and Mr. Attrill, gardener to J. Freake, Esq., fourth. A special prize was offered for nine stove and greenhouse plants in flower in 12-inch pots, brought out three good collections. The first prize was awarded to Mr. J. W. Moorman, gardener to the Misses Christy; second to Mr. Ellis; and third to Mr. Hinnell for plants somewhat smaller than the other two collections, but very superior.

Fine-foliated plants were also well shown, Messrs. Attrill, Crafter, and King sharing the honours in the class for six plants, and Messrs. Ellis, Fielder, and Gray in the class for three. Exotic Ferns were also shown extensively, and in six Mr. Hinnell was placed first, Mr. Attrill second, and Messrs. Watson and Ellis equal third; and for three Ferns Mr. Fielder, gardener to R. B. Perkins, Esq., first; Mr. J. Watson, gardener to Capt. Cundy, second; and Mr. Gray, gardener to G. B. Windeler, Esq., third.

Fuchsias were not as numerous as is usual at Kingston, Messrs. Moorman and Watson being the only exhibitors for nine plants, and were placed in the order named, both collections being very good; and for six plants Mr. Attrill was the only exhibitor, and received the first prize. Pelargoniums were shown in large numbers. Mr. King, gardener to R. Few, Esq., Wosely Grange, Esher, was first both in the nine large-flowering and nine fancy Pelargoniums, and Mr. Croxford, second; and in the class for six Mr. Kent, Mr. Hodgson, and Mr. J. Watson were awarded prizes in the order named. Tricolor and Bronze Geraniums were both well and largely shown; the scarlet-flowering section was also well represented. Achimenes and Gloxinias were very good and shown in large numbers. Dinner-table plants brought together seven competitors. Mr. R. Watson was placed first, Mr. Moorman second, and Mr. King third, all with very neat and even-grown plants.

Roses were shown by numerous exhibitors, but as a whole not up to the average of former years. The season has sadly affected them in this district. Mr. Moorman was placed first for twenty-four varieties (distinct), closely followed by Mr. Ellis, who was a good second. There were also classes for twelve and six both in the amateurs' and professional divisions, and amongst the prizewinners were Messrs. Vicary, Crafter, Leech, Clay, and Gains.

Fruit was not largely shown, but was very good, Mr. Croxford being placed first for a collection of six dishes. White Grapes came from Mr. R. Watson, Mr. Bailey, and Mr. King, who were awarded first, second, and third prizes respectively. Black Grapes were also shown well by Mr. Hinnell, Mr. Watson, and Mr. Croxford. Melons from Mr. Child and Mr. Gregory, Mr. Child winning the two first and Mr. Gregory the two second prizes. Strawberries in pots were well done, and brought eight competitors; Mr. Ellis first, Mr. King second, and Mr. Attrill third.

For a collection of vegetables, twelve sorts, Mr. Moorman was placed first, Mr. Ellis second, and Mr. Croxford third; and for six sorts Mr. Watson and Mr. Kent were first and second. Cucumbers were shown in large numbers by Mr. Child, Mr. Mills, and Mr. Eaton, who were awarded in the order named for well-grown examples.

For Sir Trevor Lawrence, M.P., the President's, special prize for groups of plants there were six competitors. Mr. Croxford was placed first, Mr. Watson second, and Mr. King third, most of them displaying superior taste, notably the first-prize collection. Messrs. Veitch & Sons staged an excellent group of Acers and Roses in pots, as well as several boxes of cut Roses in first-rate condition, and found numerous admirers. Messrs. Jackson and Sons contributed a group of stove and greenhouse plants at the other entrance, which was also very attractive. The weather was fine, and the Show was undoubtedly a success financially, and reflected credit on Mr. McMillan the Secretary.

FERNS IN COMMON SOIL.

FEELING persuaded that the day must come when Ferns will be generally grown in manure and soil instead of peat and sand, I sent you some fronds to show that mine do grow luxuriantly, and will now state exactly how they are treated. The seedlings are pricked-out into a small frame that stands on slates placed on the hot-water pipes, and four or five weeks afterwards they are potted and again placed in the frame for a few hours, then placed on beds of soil in the Fern house. If any manure is used in the pans or frames in which the seedlings are raised, a black fungus growth soon covers and destroys the young Ferns. As soon, however, as they are large enough to pot there is no danger to be apprehended from this cause, and then every Fern is potted in about two parts of garden soil (I should prefer decayed turf), and one part manure.

My *Adiantum Farleyense* are very large and seed freely. They cannot be more healthy or grow faster, I believe. They were potted the second week in March in soil brought in a barrow out of an orchard quite wet and cold. One was potted in two parts of the soil and one part of cow manure brought direct from the field. A second was potted in two parts of that cold wet soil and one part horse manure brought direct from the stable. A third was potted in two parts of the soil and one part of an old Cucumber bed. The three are all now standing together, and perhaps the one with the cow manure is not quite as strong as the others, but they are all in perfect health and have seed fronds.

Now I do not want to suggest that it is necessary or wise to pot Ferns in wet soil from an orchard, but I do say that all the labour bestowed on growing them is a waste of energy. They will give no trouble in rich soil without peat and sand, provided that they are kept moist and warm, and that the hole at the bottom of the pot is enlarged. If, however, it is not very large with my treatment the Ferns will die; and if it is very large they will grow, not like Cabbages, for it requires a good gardener to grow a good Cabbage, but they will grow as they cannot in peat and sand.

One fact and I have done. The fronds I sent were cut in a house about 50 feet by 30 feet. The only person who attends to that house is the daughter of one of the farm servants. She does not know the name or nature of any Fern, but simply with the rose of a great watering-pot keeps them very wet—almost muddy, and when she sees an insect or a weed she destroys it.—H. L.

[The fronds sent were extremely fine.—Eds.]

THE ROSE YEAR.

WE gather from many letters which we have received from various districts that 1877 is not a good year for Roses, and that cut-back plants have suffered more severely from inclement weather than maidens, and that as a rule Roses in the south have suffered greater injury to their early growth than Roses in the north. We are only able to publish a few extracts from these letters, commencing with those from districts "near home."

SURREY.—"Seldom, I imagine, have May frosts done more mischief. The wall fruits almost all gone—Peach trees with me have perished, Pears hopeless even in sheltered places. All this might have been borne but for the burned-up state of the first blooms of most Roses. I have broken off dozens of blighted buds. However, bright sunshine has repaired many mischiefs, and I incline to think our exhibitions about here will not be much below the average. The rains have come most seasonal, and probably the great National Show of

July 4th will find Surrey about at its best; at least a Reigate friend in whom I place much faith jubilantly threatens a thirty-six box for St. James's Hall, to replace his first for twenty-four at last year's Aquarium Show. Speaking of Reigate I may remark that the Reigate Committee, with its popular President Mr. Baker, had resolved on offering this year an all-England prize for thirty-six, in hopes of attracting some Hercules and Leviathan; however, the seizure of our day by the Alexandra (all honour to them otherwise for their most liberal schedule) has caused this to be deferred at any rate to another year. *Plaisir remis n'est pas perdu* (Pleasure delayed is not lost), as a lady friend of mine has just written to me. It would be great convenience if we could have two Julys. Could not our ingenious American cousins contrive this for us? That I doubt; but with reference to Rose results I will take one idea from them, 'It is never safe to prophesy unless you are sure;' but I venture to predict that in the great contest impending the best horse will win, and that a good horse (or Rose) cannot be of a bad colour.—A. C."

Mr. Jessop, writing from near Chertsey, says, "The late cold wet spring has very much retarded the growth of young wood. The ground was sodden, and then came continuous east winds, which dried up into a hard crust the clayey soil of this neighbourhood; afterwards in May came the cruel frosts, stopping the growth and cutting off the shoots that had started. In some quarters, where the ground had been stirred about the roots of the Roses and then heavily mulched, the growth has been satisfactory, some of the shoots being surprisingly strong—viz., Cheshunt Hybrid, Etienne Levet, Comtesse d'Oxford, Richard Wallace, Capt. Christy, Camille Bernardin, Peach Blossom, Emilie Hansburg, Comte de Nanteuil, and many of the old favourites. Reynolds Hole, Horace Vernet, Marie Cointet, Charles Rouillard, Duke of Edinburgh—straggling growth. Xavier Olibo is, I believe, constitutionally weak, and always seems as if making an effort to exist. Dwarfs on the Manetti are generally bad here. In some quarters, where the soil is lighter for the Manetti, grubs have played sad havoc, many of the stocks being killed outright, the fibrous roots being entirely eaten away; the Briar on the clay escaping this pest. Sultan of Zanzibar, Dr. Hooker, Duke of Connaught, Miss Hassard, and Mons. E. Y. Teas are doing fairly well. La Rosière is of a splendid colour; I think much of it. Of its form and texture another week or two will tell better. It is a poor affair thus early." Mr. Moorman communicates similar experience from Coombe, and from Buckinghamshire we have tidings of the same nature.

Going "further a-field" Mr. Camm writes as follows:—"I live just on the borders of Dorset, and the district I allude to extends from here to Exeter. I should say the prospects in this district are rather bad. My Roses have not done at all well. There is no growth, no vigour, and no likelihood of it either, so far as I can see. Mr. Baker's Roses are very backward, particularly his young plants and his maidens; in fact, up to this date he has cut all his prize blooms from old plants. Tea Roses here are very backward. The severe weather in May destroyed most of the early buds, and as I never leave a faulty bud on a tree numbers of my Teas have not yet bloomed. I believe there will be a great scarcity this year of standard Roses in the market. One or two of the great houses are very badly off for them, but I hear there are wonderful prospects for next year, and in those nurseries which I have visited I have been much struck with the grand growth of the Briars. On the whole, then—judging from my own garden, from exhibitions, and from what I have been told by the leading rosarians—I am inclined to think that the year 1877 will not be reckoned as a good Rose year."

From more northerly districts we gather from two letters from Yorkshire and one from Lincolnshire that spring frosts have only slightly injured the young growths, that the Roses have seldom looked better than this year, and have never been known so late. One writer says that the great Rose Society that is "called national" is only "half national," and that "it will not be worthy of its name until it is strong enough to hold two shows in each year—one in the south and one in the north; and until that is accomplished growers in the north, however 'warmly' they might support the Show, must be 'left out in the cold,' because Lincolnshire, Notts, and Derbyshire are a fortnight and Yorkshire three weeks later than Devon, Dorset, and the southern counties."

From Scotland we learn that the Rose prospects were never better than this year, and that growth is advancing rapidly under the genial influences of fine weather.

From Wales (South) we have an interesting letter giving a favourable account of that district for Rose culture, and that Roses generally are now looking well. As we cannot well abridge this letter, its publication must be postponed, as must also several other interesting communications on the same popular subject, although we have afforded this week additional space to Rose articles.

FRUIT-TREE CULTURE.

I HAVE read the interesting remarks of your correspondent "NORTHERN GARDENER," but do not propose at present to consider all the points he has brought forward. With regard to the law on the subject, I am still of the same opinion—that I was some time ago, that a grand result would be produced by an alteration in the way suggested; and my principal object in now writing to you is to say that I do not intend to let the matter drop, but am collecting information on the subject.

On consideration I came to pretty much the same conclusion as "NORTHERN GARDENER," that the present moment, whilst the war between Russia and Turkey was proceeding and the fag-end of the session approaching, was not very opportune for the introduction of the subject.

There was an extract in the Journal the other day from an American newspaper which stated "that fruit to the value of millions is imported here which might be just as well grown at home." That, no doubt, is true, and I hope before long we shall do it.

Besides the articles in this Journal alluded to by your correspondent, there have been several important papers and essays lately elsewhere. A paper by Mr. Webb on fruit-growing, read before the Institution of Surveyors; a paper in the "Society of Arts Journal," January 19th, 1877, on the cultivation of common fruits from a social and economical point of view; and quite recently an essay in the "Royal Agricultural Society's Journal" on fruit-growing in Kent, by Mr. Whitehead of Maidstone; so that if something is not done before long to extend fruit cultivation in this country it will not be from the want of attention being drawn to the subject on the part of the literary community.

I do not think landlords here with their present ideas would care to supply fruit trees to the tenants. The cottages are no profit now; very often a cottage and a quarter of an acre of garden ground let for 1s. a-week and the landlord expected to do repairs, and the interest put on for a few trees he would think *infra dignitate*. Perhaps they may be induced to change their ideas on the subject, if not disposed to grant the small concession of allowing their tenants to take away what were originally their own trees.

I think there is a great deal to be learnt yet with regard to Apple cultivation by observing the time in which the various kinds come into bloom, and the result on the produce of the trees. I took a few notes this year, which I may send at a future time if thought likely to be interesting.—AMATEUR, Cirencester.

[Please do so; your letters are always interesting.—EDS.]

ROSES AND THEIR ENEMIES.

AMONGST the answers to correspondents in your last week's edition I note an expression of opinion that emmets are not destructive to Rose buds. Permit me to say that my experience of growing Roses has taught me that these insects do as much injury to the buds as the caterpillar; and having regard to the great numerical strength of the emmets to the caterpillars, the former, in my opinion, do by far the most injury. From my observation of the emmets' work of destruction I am able to say that they attack the extreme point of the bud. Here they soon make a small hole downwards in the centre; in a few days the top half of the bud will be entirely eaten away, and instead of looking at a bud which a few days ago promised to turn out a fine Rose, one has now to look upon a mass of emmets comfortably lodged on the remains of the bud.

The above short record of my experience of the emmet, and, so far, its habit of destructiveness, may perhaps be interesting to some of your numerous readers who are fond of a good Rose. I grow a good many of them in my villa garden, and pride myself that I can cut a good one for a button-hole every morning from about the middle of May to, I might say, the end of the year, besides furnishing my house and numerous

friends with good wholesome bunches to decorate their tables.
—L. H., Bromley, Kent.

I THINK it is generally asserted that ants do not destroy Roses. Well, bees do not eat fruit if they can procure their usual food, but will do so rather than starve: so ants, if numerous and food scarce, will be found a great nuisance. Previous to the summer of 1875 I looked upon ants on Roses as merely indicating where a little extra attention was needed in washing to keep down the aphides; then, however, I found to my cost that under certain circumstances they were flower-eaters.

As the case is perhaps exceptional I may state that, having had to form a new rosery the previous autumn, and being close on the rock with only about 6 inches of soil, it was necessary to look around for loam suitable for bringing in; this I procured from a piece of waste land covered with ant hills. Half the ground was made up, and the Roses planted. The ground being well mulched with stable manure, nothing was seen of the ants till, in the course of the summer, the buds began to show colour at the points. Then the work of destruction began: the ants began at the apex of the buds and gradually ate all down as level almost as though cut across with a knife. At first I removed the injured buds, but finding the ants only took to the next branch to recommence operations, the injured buds were afterwards left as traps, from which swarms (I cannot find a fitter word, as they resembled nothing so much as miniature swarms of bees) were pinched off and killed many times a day. There could be no mistake about the depredators, for they were there by thousands, and were watched and destroyed constantly, as my employer required boxes of Roses twice a-week in London, and without constant attention I believe the ants would have claimed all. The same thing occurred again, but in a less degree, last summer to fresh-planted Roses, the remaining ground having been made up from the same source in the autumn. This year there is no injury done, although the ants are pretty numerous, but owing to the numbers destroyed the supply of food is equal to the requirements of those left. Therefore I infer that only in exceptional cases are ants destructive to Roses. — R. C., Castle Gardens, St. Fagan's.

ROYAL HORTICULTURAL SOCIETY.

JULY 3RD.

VERY interesting plants and cut flowers were arranged in the conservatory on this occasion—interesting at least to horticulturists; but as a "show," as commonly understood by the public, the display had no claim. As a meeting it was a good one; and it is submitted that it is a mistake to announce the ordinary fortnightly gatherings as more than horticultural meetings; to refer to them as "exhibitions" can only mislead the public, and almost certainly result in disappointment.

FRUIT COMMITTEE.—H. Webb, Esq., V.P., in the chair. Only a small amount of fruit was exhibited, and no awards were made by the Committee. Mr. Ollerhead exhibited two well-grown and perfectly ripened fruits weighing nearly 4 lbs. each of Queen Pine Apples; also a Melon the result of a cross between Colston Basset and Cox's Golden Gem, but it was not so good as it looked. Mr. Gilbert exhibited a fruit of Kasgar Melon, and although it was of good flavour it was not considered superior to other varieties in cultivation. The same exhibitor also submitted a very fine example of Criterion Peas growing on the haulm, and also a separate dish of the same good variety. Mr. Bull exhibited a brace of very large Cucumbers. A dish of a new Strawberry was sent from Messrs. G. Paul & Son, Cheshunt, and twenty-five dishes of Strawberries in as many varieties were sent from the Society's garden at Chiswick.

FLORAL COMMITTEE.—G. F. Wilson, Esq., in the chair. Messrs. James Veitch & Sons, Chelsea, exhibited a small group of very choice plants, and first-class certificates were awarded for *Cypripedium albo-purpureum*, the result of a cross between *C. Dominii* and *C. Schlimii*. It is a most beautiful variety with handsome bright green recurved leaves, and a charming flower, somewhat of the colour of the hardy *C. spectabile* but richer, the throat being finely spotted. Also for *Rhododendron Countess of Derby*, one of the javanico-jasminiflorum type. The colour of the flower is rich pink suffused with orange, very fine, and rendered further attractive by the contrasting dark stamens—a valuable addition to a valuable class of plants. A similar award was made for *Alcassia Thibautiana* from Borneo, one of the grandest *Alcassias* that has ever been introduced. The plant is of stately habit, has very large deep green leaves with a distinct midrib and prominent grey veins. It will be indispensable as an exhibition plant. Also to *Aërides crassifolia* with very

large rosy purple flowers, very fine. A certificate was also awarded to the fine rare Orchid *Vanda Parishii*. Messrs. Veitch also exhibited some curious *Masdevallias* and other plants.

A valuable collection of *Liliums*, *Calochortuses*, *Alliums*, *Ornithogalums*, and other bulbous plants, also *Irises*, &c., were staged by J. T. Elwes, Esq., Preston, Cirencester. These were both choice, rare, and beautiful. Amongst them we noticed a striking variety of *Lilium auratum* var. *Wittei*, with long pointed waxy-white segments banded with yellow. *Xiphion lusitanicum* var. *sordidum* was very rich; and extremely beautiful were *Lilium parvum*, *L. Szovitzianum*, *L. Washingtonianum purpureum*, a crimson variety of *L. elegans*; also *L. elegans* var. *alutaceum*, orange-yellow. *Calochortus splendens* and *C. venusta* were particularly striking. The collection was highly commended, and a vote of thanks was awarded to Mr. Elwes.

Messrs. Barr & Sugden also arranged a varied and most attractive collection of *Liliums* in about forty sorts, also twelve splendid varieties of *Iris Kämpferii*, which were as striking as *Cattleyas*. To two of these *Irises*—Robert Parker, silvery-grey, heavily veined with violet; and Mrs. Barr, pale lavender, veined with lilac—first-class certificates were awarded. G. Maw, Esq., Benthall Hall, Broseley, Salop, also exhibited cut blooms of *Liliums*. *L. Chaixii* from the Maritime Alps—a striking form of *L. croceum*, the fine orange-yellow flowers suffused with crimson being borne in umbels and not in whorls like those of the species—was awarded a first-class certificate. *L. elegans* var. *Mawei* received a similar award. It is a very striking flower, large and richly spotted. *L. pomponium verum*, with small much-recurved crimson-scarlet flowers and very slender foliage, was highly attractive. *L. canadense* from Heavesville, Canada, had large and finely spotted flowers. Mr. Maw also exhibited flowers of the old *Salvia interrupta* from Morocco, and other old rarities.

G. F. Wilson, Esq., Weybridge, staged *Lilium japonicum* (Kramer) in variety, *L. callosum*, *L. Columbeanum*, and *L. avenaceum* from his choice collection. They were very attractive.

Mr. Turner, Slough, exhibited cut blooms of *Show Pelargoniums* in nearly seventy varieties, these were highly effective; a Tree Carnation, Lady Avenel, pure white, smooth, and fine; and a new seedling Rose, Penelope Mayo, a fine, full, excellently formed flower and bold foliage; it somewhat resembles Marie Baumann, and is fragrant. Cut Roses were also sent by Messrs. George Paul & Sons, Cheshunt, to one of which, Marchioness of Exeter, a first-class certificate was awarded—a fine Rose with recurved petals; colour rosy pink, deepening to salmon in the centre; also fragrant. A new crimson Rose, Duke of Teck, was also exhibited, but it was too fully expanded; also John Bright, rich velvety crimson. Messrs. William Paul and Son, Waltham Cross, also exhibited some seedling Roses, to one of which, May Quennell, a first-class certificate was awarded. This is a grand Rose, of fine form and with great substance of petal. The colour is warm rosy crimson, shading to magenta in the outer petals. The foliage appears also to possess the same stout texture of the flowers. We think a finer Rose than this has not appeared from Waltham. Another Rose exhibited in the same stand we thought deserving of honour—a Moss Rose named Little Gem, which will make its way as a garden Rose, and be in request for cutting. It is very small, very free, and very mossy. Some other Roses exhibited from the same nursery will be heard of again. A Rose named Burghley Yellow was exhibited by Mr. Gilbert, Burghley, and for which the exhibitor was awarded a vote of thanks. It was considered to be a very old Rose which was cultivated years ago as the "Old Yellow." The foliage is small, glaucous, and singularly formed. The blooms submitted were also well formed and of a bright Calceolaria-yellow colour. Is it a good grower, Mr. Gilbert? If so increase it, for it is a most distinct and attractive Rose.

Messrs. James Carter & Co., 237, High Holborn, exhibited a collection of Sweet Peas, including a new variety, very attractive from the curious mixture of purple and scarlet in the flowers; also some new *Eschscholtzias*, to which first-class certificates were awarded. One, a double bright yellow variety. *E. crocea flore-pleno*, and the other *E. crocea* (aureo-coccinea) Mandarin, the buds and exterior of the flowers being scarlet and the interior orange. It is the greatest advance in *Eschscholtzias* that has been yet seen, and will prove one of the most gorgeous of hardy annuals.

Mr. Cannell, Swanley, exhibited twenty-four very fine varieties of *Verbenas*, also cut blooms of Sweet Williams of an excellent strain, and received a vote of thanks.

Mr. Parker, Tooting, exhibited flowering sprays of *Freemontia californica* from a shrub which has not been protected for two years, and received a vote of thanks. It is a deciduous Californian shrub, with handsome yellow flowers as large as those of *Eschscholtzias*. Messrs. F. & A. Smith, Dulwich, exhibited new decorative show *Pelargoniums*, also a fine double crimson-and-white fimbriated *Petunia*.

Amongst other exhibits to which awards were not made we noticed flowering sprays of an *Andromeda* named *A. crassinifolia* from Mr. Ollerhead, The Gardens, Wimbledon House

(*A. crassinefolia* of Ventenat; syn. *A. speciosa* of Michaux). The sprays were laden with paper-white, globose, campanulate flowers, and were very beautiful. It is a native of Carolina, and being hardy is worthy of more extended cultivation.

OLD ROSES.

At last we—I mean myself and your correspondent “WYLD SAVAGE”—understand each other. He does not condemn old Roses and large trees of them as such, but only because they are not suitable for producing exhibition blooms for the great shows. Had he been as explicit before, he would have saved both his time and mine; but I daresay neither of us begrudge half an hour occasionally in a discussion so congenial and agreeable as that of the Rose, especially in those columns which have done, are doing, and will do so much for the increase and cultivation of both old and new Roses—Roses for the garden and Roses for the exhibition.

I cannot say for how many years I have been a reader of your Journal, nor how many times I have been entertained by the refreshing letters of my—shall I write it?—opponent. I have written the word; but it is wrong as it stands, so I will qualify it, and in all sincerity refer to him as my highly respected opponent. But although I have been a reader so long I was not aware that I could write until someone “trod on my corns,” a matter which few Yorkshiremen will endure in silence. And now the Editors have been appealing to my vanity to write more! Note that, “WYLD SAVAGE.” Is it not proof that they do not despise old Roses?—those glorious dangling masses of beauty which grace the wall, the bower, the rock with their incomparable trusses, and dispense their perfume—their own inimitable fragrance—in garden and dwelling. They may not value them so highly as they do exhibition Roses, for to the latter I see that they offer a cup which will have been won at the “National” before these lines appear in print. How I should enjoy a visit to that great tournament! but if I cannot see it I can do the next best thing—read about it. There will be grand new Roses there and good old Roses, also old rosarians and young. I hope especially that “WYLD SAVAGE” will be there to win and to write, for I like his free criticism better than elaborate formal “reports.”

The truth is that many old Roses would be found in the winning stand were as good stocks and equally good cultivation given them that are given to the new. I do not believe in the degeneration of Roses, but I do in the degeneration of Rose culture as applied to the good old sorts. When a new Rose is obtained the best stock is selected for it and the best position; and old Roses, if they are budded at all, are budded on the inferior stocks—the outsiders—the “culls.”

Your correspondent, my respected opponent, has directed my special attention to the peerless beauty of Marie Van Houtte. I grant that that is a charming Rose which all should grow who can do so; but all cannot grow that dainty gem who can grow the old, the valuable old Rose which was in such grand form at Exeter, Jules Margottin. This is a Rose that will grow anywhere—in the balmy air of Devon or Dorset, in the bleak fens of Cambridgeshire, and on the bluff moors of Yorkshire. Will Marie Van Houtte do so? I think not. As an exhibition Rose, a button-hole Rose in the opening-bud state, and as a garden Rose to grow into a tree and produce hundreds of rich glowing pink blooms, tell me—I ask the question seriously—of a better Rose than Jules Margottin?

I do not intend at present mentioning the old Roses which I have alluded to before; but one which I have not mentioned is just now opening its blooms—there will be at least a hundred of them on one “tree,” and not a few of them of exhibition quality—I mean Paul Ricant. I cannot afford to despise that good old Rose, although he does not continue blooming like another old friend, the “Jineral” (*Général Jacqueminot*). Already has that good old servant twice received honourable mention at the Rose shows this year. Talk about degeneration! I do not believe the “Jineral” will sooner degenerate than will York Minster, provided both have what they deserve—reasonable care. I have *Général Jacqueminot* as good now as he was twenty years ago; but he is on good stocks, and has his wine (liquid manure) regularly every spring just when growth is commencing. He is a noble Rose. I have him, too, on his own roots and planted in a mass with (I know it requires a Yorkshireman's nerve to write it) the old Monthly China Rose, and a valuable old white Rose one seldom hears of now-a-days—Mrs. Bosanquet. A few of *Acidalie*, another white Rose,

are growing in the same bed, a bed from which I expect to cut blooms—many good enough for exhibition—until next December, and it may be January. What other quartet of Roses will do that so well as those named?

I was about to apologise for my temerity in mentioning the old Monthly China Rose, but I will not do so, for a real lover of Roses who “went south” last year told me of its beauty at the Crystal Palace, where it is grown (he informed me) more largely than any other Rose. I can quite understand how beautiful and long-continued in its beauty it is when planted in long lines, as I am told it is at the Palace, for even in Yorkshire the bushes are laden with blooms throughout the summer months. It is the first Rose and the last, rendering the garden cheerful and the vicarage rooms gay.

Let me say another word in favour of Mrs. Bosanquet. If the frost cuts it down to the ground it springs up vigorously, and the same season produces chastely-formed almost pure white flowers, than which few are more welcome when out for vase decoration; and the more you cut the faster they seem to come, continuing almost throughout the season. It is also one of the best of Roses for forcing, at least for such quiet forcing as a quiet family like ours requires. We start a vinery on the 1st February, and fill it with Roses, and the Rose that gives nearly the earliest blooms and always the most of them is Mrs. Bosanquet.

If I say anything about *Gloire de Dijon* it will be a simple record of my opinion that it is the most useful light-coloured Rose ever raised, as I think Jules Margottin is the most useful of deep pink colour, and the “Jineral” the most serviceable crimson.

I have some other old—no, not old, but only oldish—Roses for which I have a liking, and I think “WYLD SAVAGE” might like them too, because they are not only good garden Roses but yield exhibition blooms. They are Charles Lefebvre, *Sénéateur Vaisse*, Alfred Colomb, La France, Baronne de Rothschild, John Hopper, Comtesse de Chabillant, Exposition de Brie, Marquise de Castellane, and a few others which I expect will be honoured at the National Show. I have also some newish Roses, which I shall not now further refer to than to say that, good as they are, they will not drive the old favourites out of the garden, for the old Roses give blooms by hundreds when the new Roses give them only by dozens, and often not at all.

But I have one new Rose which under glass is a gem, only feed it well and thin out its buds. It is Madame Lacharme. “WYLD SAVAGE,” recant! Did you not once “speak ill” of this fair Rose?—A PARSON'S GARDENER.

[He has recanted.—EDS.]

CARBOLIC ACID VERSUS MICE.

WE have been very much troubled with mice in the kitchen garden this spring. Half of the seed was taken out of some of the rows immediately after it was sown. I tried nearly everything I have ever seen recommended to keep mice from destroying the seed, and not one of them was so effectual as coating the Peas over with carbolic acid, and allowing it to dry on before sowing.—J. H. Y.

DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

KITCHEN GARDEN.

WE hear of genial showers of rain in the neighbourhood of London. The crops on the dry and loose soil of the Essex level have suffered from the prolonged drought, but as far as the kitchen garden is concerned we make our preparation in the winter by deep digging or trenching, and manuring with moist cow and stable manure placed at a considerable distance under the surface of the ground, and our crops have not yet suffered. “J. B. K.,” writing in last week's Journal on the substitution of artificial manure for Roses, may be quite right in regard to the chemical nature of the constituent parts of the fertilisers, but we would prefer manure. It is not so much the amount of water the manure contains when it is applied to the ground as its capability to absorb and retain water until it is needed in the summer that renders it valuable, and more unfortunate still would be the want of manure for mulching the ground after watering. Other substances might be placed on the surface, but we do not know any so valuable as good manure.

It is a good plan to sow such crops as late Peas in shallow trenches. Dig out the trench first, say 4 inches deep, and then draw a drill in the bottom of it and sow the seeds. The crops

do not require any earthing-up, as enough soil for this purpose falls in the bottom of the trench when water is applied. When crisp Lettuces, Radishes, and other salads are required at this season the best place to sow the seeds is under a wall facing north, and even there it will be necessary to water freely in hot dry weather.

Peas are bearing well. William I. has been the earliest, although it was closely followed by Alpha, a better Pea as regards flavour, although the first-named sort would be much the best variety for market purposes; the pods are larger and of a deeper green colour. If Leeks are not planted no time should be lost in getting them out. They ought to be planted early in June, or even in May, to give the best results. The variety called the Musselburgh is considered the best. In Scotland every garden has its bed or quarter of Leeks, and they are used all through the winter months. They are planted in rows a foot apart, and 9 inches between the plants. A rather deep drill should be drawn first, planting in the bottom of the drill. The portion of the Leek most esteemed is that part which has been blanched under ground, and well-grown specimens will have a foot in length blanched, and be very nearly as much in circumference. The cottagers in Scotland reserve the best pig manure for their Leeks, and the plants are not allowed at any time to suffer by want of water.

VINERIES.

Red spider, which has not been very troublesome until the last two weeks, is now showing itself. We still hold that painting the pipes with sulphur that has been made into a thin paste by means of soapy water is the best way to destroy this pest. Many good gardeners, amongst them the late Mr. Pearson of Chilwell, doubted this. It is a question whether they have applied the sulphur in the right way. We have usually heated the pipes first to the proper heat, and then applied the mixture. It is just possible that if the pipes were gradually heated to the required temperature after the sulphur has been applied the effect of it might not be so apparent. We generally find the spider has been destroyed after three dressings. A correspondent last year recommended heating shovels to a certain temperature and then dusting the sulphur on to them. This we have done this year, and although many spiders were seen alive after the operation, they received a considerable check; and if we had persisted in it four nights instead of two possibly it would have been entirely destroyed. We shall soon clear the Grapes both from the early Hamburg and Muscat houses, when it will be an easy matter to destroy the spider by syringing the leaves. The difficulty usually is to retain the leaves in a healthy state until the fruit has been cleared off.

Where Grapes are nearly ripe in succession houses it is probable that there may be some small or shanked berries on some of the bunches; these ought to be carefully removed at once, as they serve to spoil the effect of a whole houseful of Grapes. Black Hamburg Grapes colour best if they are shaded by the leaves; but to produce the rich amber so much esteemed in Muscats it is better to push the leaves gently aside, or even to remove them altogether. The same remark applies to most other varieties of white Grapes.

We have just finished thinning-out the Grapes in the late houses. We close early and keep the atmosphere rather moist. Artificial heat is not needed in any of the houses; for even if the thermometer does fall considerably at night it is only for an hour or two, as by shutting up with sun heat early in the afternoon the temperature does not fall below 70° until near midnight, and the sun begins to have an effect on the temperature between 4 and 5 A.M. We would rather have the lower night temperature, as under that treatment red spider is not so likely to attack the leaves.

Vines in pots which have been grown-on for early forcing will now have completed their growth, and it will be well to see that the wood is sufficiently ripened; this will not be done by withholding water and admitting plenty of air. Although the wood appears to be ripe it may not really be so. The main object of the cultivator is to develop the buds from which the fruitful spurs will start next season. To do this water must be applied to the roots and leaves as usual, and a high temperature should be kept up. If the Vines are not (as they ought to be) already in their fruiting pots, lose no time in potting them as previously directed.

PLANT STOVE AND ORCHID HOUSES.

The hot drying weather has necessitated much watering and syringing. It is certainly better to keep plants clear of insect pests than it is to destroy those pests after they have become established on the plants, and to keep the plants clean it is necessary to see that they are in a healthy growing condition; and those plants that will bear syringing ought to be dewed overhead at least twice a-day, and in some instances the water ought to be applied with considerable force. Watering must also be carefully attended to. A plant may be either over or under watered, but this will not really happen with those who understand their work and give the requisite amount of attention to it. It is better to allow the potting or such work to stand over

for a few days than to neglect the watering of plants when they are in full growth.

We have been basketing and repotting Orchids. Where there is a large collection of these interesting plants to attend to, those in charge of them find plenty of employment for every day in the year; and almost every month from spring until autumn something requires to be done in the way of repotting, basketing, fixing on blocks, &c. When the wants of the plants are known there are few subjects more easily grown, but if a check is experienced from any cause it may be years before the plant recovers. Another thing, you must not be in a hurry with them—they will not be driven. If an Orchid flowers a month or two earlier this year than it did last, this we consider evidence that the temperature is too high, and probably if this should be continued the plants will sicken and die. When they flower about the same time each year it is reasonable to suppose that the temperature at least is suitable. The beautiful *Masdevallias*, which are so easily grown and increased, are not new introductions; at least, not all of them, but those that were introduced prior to the cool-house system perished miserably. The same fate befell many of the choice *Odontoglossums*, which are quite as easily managed as the others. We have now learned to avoid the rock on which our predecessors foundered, and we keep the cool Orchid houses cooler than the outside air during the summer months. *Masdevallias* and *Odontoglossums* have been repotted, and as the plants require a considerable supply of water the pots are filled about three-fourths of their depth with potsherds. Cattleyas, such as *C. Warneri*, *Mossiae*, *Mendelii*, &c., have been repotted. These species are now making fresh roots, but we find that after repotting they do not flower so freely the next season. Large specimens require repotting but seldom. Some of the best cultivators say once in seven years is often enough, others say they ought to be repotted every alternate year. We saw at Messrs. Veitch's nursery, King's Road, Chelsea, the other day, many large specimens that had not been repotted for many years. The leading growths had grown over the sides of the pots, and a wig of roots depended from their base, showing conclusively that the roots were aerial, and depended for their sustenance not from what they extracted from the potting material (into which they had no inclination to travel), but from the atmosphere. It is so with many Orchids; they do not succeed until a large proportion of the roots hang over the sides of the pots. After repotting a moister atmosphere is maintained than previously.—J. DOUGLAS.

TO CORRESPONDENTS.

* * All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

BOOKS (*T. J. C.*).—You must apply to the publishers, Messrs. Bell & Co.

TRAPS ON VINES (*M. D., Forest Gate*).—The leaves sent are very much infested with thrips. When a few leaves only are attacked an excellent remedy is to sponge them with strong soft-soap water made by dissolving 4 ounces of soap in a gallon of water. If all the leaves are covered with insects fumigate the house with tobacco on two consecutive nights, then syringe the Vines as heavily as possible, directing the water between the bunches. In a week or ten days other insects will appear from eggs deposited on the Vines, and fumigation must be repeated.

ATLANTUS (*A Diligent Reader*).—The leaves you enclose are not *Ailantus* leaves.

BOXES FOR SHOWING ROSES (*A. D.*).—The boxes which close for travelling can be made by any carpenter, and of the size desired. We know of none ready made. The Rev. Canon Hole has given the following dimensions and instructions:—

	Length.	Breadth.	Height.
For 24 Roses,	4 feet.	1 foot 6 ins.	Back of box, 6 inches, front 4.
" 18 "	3 feet.	" "	" " " "
" 12 "	2 feet 2 ins.	" "	" " " "
" 6 "	1 foot 6 ins.	" "	" " " "

The covers, being 7½ inches in depth at the back, and 5 inches in front, 4 feet 1 inch in length, 1 foot 7 inches in breadth, and having a narrow beading within the four sides, half an inch from the bottom of the lid, overlap the boxes, leaving ample room for the Roses, and are secured for travelling by stout leather straps. Within the boxes some exhibitors have holes pierced at equal distances on a uniform surface of wood; but as Roses differ in size, it is more convenient to have the facility of placing them where we please, and for this purpose it is desirable to have strong laths (three-fourths of an inch in depth, and 1½ inch in width) extending the length of the box. These laths should be six in number, and should be nailed on two strong pieces of wood, crossing the box one at each end, 2 inches below the surface. The upper and lower laths should be fixed one-eighth of an inch within the box, and the four remaining so arranged that there will be five interstices 1½ inch in width—three for the Roses, and two merely to reduce the weight. There will be a space of 1½ inch between the laths and the upper edge of the box, to be filled as follows:—Cover the laths with sheets of brown paper, two deep, and cut to fit the box, and upon these place the best moss you can obtain."

DRAEENA UNHEALTHY (*E. H. B.*).—As you do not state what *Draeena* it is "looking rather shabby," we cannot say whether it ought to be planted out during the summer or not. A book which gives simple and brief directions for the culture of these and other subtropical plants, can be obtained from Mr. B. S. Williams, Victoria Nurseries, Holloway, London.

PROPAGATING LEUCOPHYTON BROWNI (J. B.).—The above is the name of the plant of which you have enclosed a spray. Full information on the best mode of propagating it appeared in No. 517 (June 21st) of the present volume of *The Journal of Horticulture*.

ANTS ON PEACH TREE (E. D. Lyon).—Invert a saucer in a larger saucer, keep the latter filled with water, and place the pot on the inverted one.

ROSE CUTTINGS FOR NEW ZEALAND—Nelson asks for information how and when to send them. We shall be obliged by a reply from anyone who has succeeded.

ROSES FOR EXHIBITING (Tyro).—The best blooms are produced from buds which have continued dormant until the spring after they were inserted. For destroying aphides try the weaker solution you name, and if it fails increase the strength.

RANUNCULUSES (A. Boyle).—They are apparently the Dutch Ranunculus imported by the seedsmen, and are described in their catalogues as Persian Ranunculus.

FERNS (S. Elliott).—There is a list of them and cultural directions in the "Garden Manual," published at our office.

ROSE BUDS INJURED (J. F.).—High winds and low temperature have shrivelled the points of the buds.

NAME OF ORCHID (J. B. C.).—*Dendrobium Paxtonii*.

NAMES OF PLANTS (J. P. Allen).—1, *Negundo fraxinifolia*; 2, *Rhamnus alpinus*. (H. R. C.).—1, *Homocallis flava*; 2, *Diplacus glutinosus*.

POULTRY, BEE, AND PIGEON CHRONICLE.

POULTRY AND BIRD NEWS.

We hear that a controversy is being waged in southern Ireland on the identity of a song bird. The London *Standard* says, "A golden-throated chorister has been ravishing belated listeners with its woodland notes from the grove by Nenagh Mills for nights past." This bird is supposed to be the Nightingale, and its strains, we are told, are very beautiful. But, unfortunately, Goldsmith, Stewart, Marshall, and other authorities maintain that the Nightingale never visits Ireland, and so students of natural history imagine that this songster is a Blackcap, or Woodlark, or Reed Sparrow, all of which warble sweetly at night. We believe this is the first occasion upon which a controversy has ever been started upon the subject, so certain have our Irish friends been hitherto that no Nightingale has sung in their woods and glens.

Lord Huntingfield's gamekeeper recently shot a fine specimen of the Osprey Eagle. It measured from tip to tip 5 feet 2 inches.

It is wonderful how tame birds become by kindness. The Rev. C. Humphrey Cholmeley of Dinton Rectory, Wilts, has for some years been in the habit of placing portable birds' nests about his garden. They are formed from decayed branches of trees, and are hollowed out, with a small hole made in the side to admit the bird, while a lid on hinges closes the top. Tits of all kinds, Nuthatches, &c., have annually built in these nests, and the other day we had an opportunity of seeing them and their inmates. One, which was placed on a ledge on a kitchen garden wall, most especially pleased us. It contained a family of ten little Blue Tits, which when fully fledged were piled one on the top of the other. This nest was not only daily removed from the wall for inspection, but was carried about for visitors to look at, and on some occasions was even taken indoors for several minutes. The parent birds were, however, not the least disconcerted, and waited on a neighbouring tree, caterpillar in mouth, for the return of their family, evidently feeling quite certain in their minds that their brood was in safe custody and had not fallen victims to a devastating cat or any such creature of prey.

A gentleman, whom many of our readers knew as a most successful exhibitor of poultry, about three years ago went out to Natal to farm Ostriches. He tells us that the present fashion of Ostrich feather-trimming for ladies' hats, jackets, dresses, &c., has very greatly improved the trade, and has increased the price during the past few years about 20 per cent. In 1874 feathers were used in England to the value of nearly half a million of money. For these Ostrich farms but little capital is necessary, and the risk is small. Another one engaged in it says, "I hold that from 300 to 400 per cent. of profit can safely be calculated on upon the outlay both for birds and other expenses, such as enclosures, plucking stalls, 'kraals,' and land rent."

Two men, named Reuben Williams and James Cameron, were convicted of fraud at the Central Criminal Court last week. They had painted a Sparrow to imitate a Bullfinch, and had sold it as such. James Cameron was sentenced to six months' imprisonment, and Reuben Williams to half that period, but both with hard labour.

We read in a contemporary that from a Blackbird's nest near Southend-on-Sea have recently been taken two "snow white Blackbirds." Their eyes are pink, and they are very promising specimens. The same contemporary tells us this pair of birds are on view alive at Mr. W. Nickats, Ingleside, Edmonton. We have seen white Blackbirds and also pied specimens, but never two snowy white from the same nest.

We learn from *Land and Water* that Mr. Bell has succeeded in rearing some young Emus in Dumfriesshire. The female bird laid nineteen eggs, and the male was allowed to sit upon eleven of them, of which six have hatched. We hear these little ones are growing fast, and are very beautiful to look at, being striped with black and white. They are being fed upon biscuits crumbled and mixed with oatmeal and green food. We consider this very interesting, and hope Mr. Bell may be fortunate in bringing them up.

It will be remembered that Mr. T. C. Burnell had his beautiful Dorking cock (second prize, we believe, as a cockerel at the Aquarium) mispenned at Banbury. The Committee have awarded this bird an honorary first prize most deservedly, Mr. Burnell with his kind thoughtfulness having objected to putting the Committee to the expense of awarding a prize in money, though the mispennings we conclude originated with them, the bird having been penned in the disqualified pen, which pen we at the time mentioned in our report.

Incubators seem to be creating a sensation at the present time. This is truly an excellent occasion, for eggs are now cheap, and the risk of hatching is perhaps smaller. So those wishful of starting an incubator during the coming spring would do well to try at once, so as to get their hands in. We hope to give a paper on the subject at an early date.

We hope that one of the next chapters of the "Basses Cours" will be on the very celebrated yards of the Countess of Dartmouth, to be followed by those of the Rev. Hans Hamilton, Mr. Q. B. C. Breeze, Mr. Leno, and others.

Messrs. Cassell, Petter, & Galpin are bringing out in monthly parts a book on Canary birds, &c. Each part will be richly illustrated, and the whole work will be such as has never before been attempted by any one authority.

A circular is in existence concerning a poultry farm. We would recommend all our readers to carefully study the matter before taking a share. We cannot imagine that those experienced in poultry lore have set this scheme afloat. The circular states that in June chickens from fifteen to sixteen weeks old may command the price of 4s. 6d. to 8s. each. We can only say that in the country we are now able to procure a brace of really good fowls for 4s., and we cannot believe these prices would remain so low if in London one bird will make more than that sum. We do not know where this farm would be situated, but we see 1s. 6d. per dozen is charged for eggs, while no carriage expenses are put down in the list of expenditure. We are now living two hours from London, and from the first week of March to the present date we are able, and have been able, to procure freshly laid eggs at 1s. the score. This speaks for itself, and novices should be on their guard.—W.

THE BIRMINGHAM POULTRY EXHIBITION.

A MEETING of the Committee was held at Bingley Hall on June 25th, under the presidency of Mr. G. C. Adkins, for the purpose of revising the schedule of prizes for the coming year. A number of alterations were made, and some of the prizes slightly reduced, in order to find money for one or two additional classes without increasing the total amount to be competed for.

For instance, the value of the cups in the Brahma classes were reduced from £5 to £4 to put them on a par with the other breeds; and the second prize in several cases, where the entries are usually small, was reduced from £1 to 10s. In the class for Cinnamon and Buff Cochins the first prizes were increased from £2 10s. to £4, and the two special cups for this breed abolished. The prizes for Black Cochins were increased. Hitherto the old and young birds have competed together, but henceforth they will have separate classes. A new class was introduced for Langshans, cock and hen of any age, with prizes of £2 and 10s. Considerable alterations were made with regard to the selling classes. Up to the present time they have been confined to Brahma Pootras, Dorkings, and Cochins, but a new class has now been opened for all other varieties, with prizes of £2, £1 10s., £1, and 10s. The entrance money has been reduced in these classes from 8s. to 5s. per pen, and the maximum price is in all cases fixed at £2 per pen.

Coming to the Pigeon department the classes for Short-faced Balds and Beards were again amalgamated, as the change did not come up to the anticipations of the Committee. An additional prize is given to the Tumblers of any other variety, and the Trumpeters are divided into two classes—mottled and any other colour. The silver cup hitherto given to Runts, Archangels, and Fantails will be competed for by the two former breeds and an extra one given to the Fantails; a third prize is given to the Fantails of any other colour. An additional silver cup is offered for Jacobins, and that hitherto competed for by Jacobins, Turbits, and Owls will be devoted to the two latter kinds. An extra silver cup is given to the Dragons and also to the Antwerps. A selling class is opened for a pair of any variety of Pigeons, with prizes of £2 and £1, the price of the pen not to exceed £2.

It was unanimously resolved that the Council should be requested to permit the poultry Committee to publish the names of the Judges in their department of the Exhibition before the closing of the entries. This was done on the last occasion, and gave such universal satisfaction to the exhibitors that there cannot be any doubt as to the result of the application. This practice is now followed at all the leading shows, and when the gentlemen selected have the confidence of the public, as is always the case at the Birmingham Show, the number of entries is materially increased.

DONCASTER POULTRY SHOW.

THE fifth annual Show of the Doncaster Agricultural Society took place last week on Wednesday, Thursday, and Friday. Previously a well-wooded park has been at the service of the Committee; but in this case the race-course with its permanent sheds was brought into use, the poultry, &c., being well protected, but the visitors finding the loss of the splendid foliage, which was a great protection from the heat of the sun. The entries in poultry and Pigeons were not large, but the prizes were very good, and some capital quality competed for the honours.

Game headed the list with single cocks, the awards being made to Brown Reds in all cases. Singularly one of the best in the class was not noticed, pen 436 (Fludger). The only fault was the tail was a little too heavy. The first going to a badly squirrel-tailed bird; the second in our opinion being the best all-round bird. Black Reds in pairs a good class; the first a grand pair, and the cup for the best Game awarded to them, although closely pressed by the second-prize pen, which contained a powerfully built cock; third grand in shape but sadly faded in colour. Brown Reds good in quality, but first no match in legs. Duckwings were queerly placed; first a bird bad in all respects, but the hen a real good one. By far the best two pens were Martin's (placed third), and Mason's (highly commended). Any other colour were good Piles and rightly placed. *Dorkings* had two classes and were all well placed, the Silver-Greys being especially good. The cup for the larger varieties was given to a capital pen of *Spanish*, the class being very good throughout; pen 488 (Bolton) contained a grand cock. *Brahmas*, Light, a fair lot and well placed, as also the Dark *Brahmas*. In *Cochins* the winners should have changed positions; the second pen good all round, and the cock of such colour as is rarely seen; the first not in the best order. *Hamburghs* not numerous but good and well placed throughout, as also the *Polish*. *Bantams*, Red, first Black Red, good in style and general quality, to which we would have awarded the cup, which, however, went to a pen of Duckwings, the cock in which was not in the best order; the second in our opinion being superior. In Reds we liked a pen of Brown Reds, but the cock was light in eye, and in consequence was thrown out.

Pigeons were not well provided for as regards classes, and the entries in consequence very few, the best in the Show being the Antwerps and a few pens in the Variety class, and the awards were well made throughout.

POULTRY.—GAME.—Cock.—1, W. & H. Adams. 2, C. W. Brierley. *Black-breasted and other Reds.*—Cup, C. W. Brierley. 2, J. Fletcher. 3, W. & H. Adams. *Brown and other Reds, except Black-breasted.*—1, W. & H. Adams. 2, C. W. Brierley. 3, Sales & Bentley. *Duckwings and other Greys and Blues.*—1, Sales & Bentley. 2, Dr. Cameron. 3, H. E. Martin. *Any other variety.*—1, H. Mason. 2, R. Walker. *Dorkings.*—Silver-Grey.—1 and 2, W. Roe. 3, Mrs. Whitwell. *Any variety.*—1, B. Smith. 2, E. Snell. 3, J. Walker. *SPANISH.*—1, J. Powell. 2, J. Boulton. 3, R. Newbitt. *COCHINS.*—1, J. Walker. 2, H. Tomlinson. 3, R. P. Percival. *BRAHMAS.—Light.*—1, J. Cherry. 2, R. P. Percival. 3, J. T. Wolstencroft. *Dark.*—1 and 2, J. F. Smith. 3, J. Walker. *HAMBURGHES.—Silver-spangled.*—1, H. Beldon. 2, Holmes & Destier. 3, J. Rawnsley. *Silver-pencilled.*—1, E. Snell. 2 and 3, H. Beldon. *Gold-spangled.*—1 and 2, H. Beldon. 3, Holmes & Destier. *POLANDS.*—1 and 2, H. Beldon. 3, R. Newbitt. *BANTAMS.—Black-breasted and other Reds.*—1, E. Newbitt. 2, A. S. Sugden. 3, W. F. Entwistle. *Game.*—Cup, R. Newbitt. 2, F. Holt. 3, W. Roe. *CREVES.*—1, T. Derry. 2, H. Beldon. 3, Robinson & Myers. *ANY VARIETY.*—*Chickens.*—1 and 2, B. Smith. 3, Dr. Cameron. *GUINEA FOWLS.*—1, E. Snell. 2, F. Clater. *TURKEYS.*—1, J. Walker. 2, W. Wykes. *Ducks.*—*Aylesbury.*—1 and 2, J. Walker. 3, R. Newbitt. *Rouen.*—1, J. Walker. 2, E. Snell. *Any other variety.*—1, J. Walker. 2 and 3, W. & H. Silvester. *GEES.*—1, J. Walker. 2, H. Beldon. **SELLING CLASS.**—1, E. Newbitt. 2, C. W. Henshall. 3, H. Elwis.

PIGEONS.—CARRIERS.—1, J. E. Crofts. 2, O. E. Mason. *JACOBINS.*—1, J. E. Crofts. 2, W. Parkinson. *ANTWERPS.*—1 and 2, W. F. Entwistle. *ANY OTHER VARIETY.*—1 and 2, J. E. Crofts. *FANTAILS.*—1 and 2, J. Loversidge. **SELLING CLASS.**—1, A. & W. H. Silvester. 2, O. E. Mason.

JUDGE.—Mr. J. Dixon, Bradford.

AQUARIUM CAT SHOW.

JUNE 27TH, 28TH, and 29TH.

Of the arrangements we can say "Very good indeed." Clearly printed catalogues, very sweet hay, red cloth cushions with cruciform-shaped brass nails to suit the advanced party, and yet not to dispirit "the other one," apparently very sweet milk, and competent Judges, whose names were Mr. Tegetmeier and our old painting friend Mr. Harrison Weir.

There were 181 Cats, many of them "Londoners," perhaps among them some of those roof-and-tile frequenters; but there were champions too there, heroes and heroines of many exhibitions; but we were sorry to find so many good specimens

entered in wrong classes. We noticed several good ones in wrong departments; and though many of the crowd of visitors were ignorant of this wrong classification, still we saw at a glance that several good animals were put out of competition in consequence. Short-haired male Tabbies we much admired. In Reds the cup went to an animal in lovely condition; while the second was also of great excellence, being beautifully marked, and the fur very glossy and bright. Black-and-white and the Black Short-haired males were not so good, and some prizes were withheld, while in Whites there were no entries at all. In the Long-haired White males Miss Hales took the only prize that was awarded. Her animal was a good one, but he did not appear to advantage when we looked at him. In Long-haired Tabbies Miss Brasey won the cup with a nice Cat, looking well, and the coat in bright condition. Mrs. Scarnan was a deservedly successful exhibitor. Her Short-haired Tortoiseshell female we liked immensely. We do not know if this individual Cat won a prize, as it had no card when we saw her, but her Short-haired gelded animal was in fine coat, and won, we believe, first in its class. The black on Miss Hales's Long-haired gelded Cat was very deep and glossy, and the creature was in good looks generally, while the fur on the first Long-haired female (Miss Sprague), was of beautiful texture and very white. In the Long-haired female variety class Mr. A. F. Turnbull, we believe, won the cup; while the same exhibitor also won the cup for kittens under six months old. There were three Selling classes for Short-haired and Long-haired adults, and for kittens. The latter class was especially well filled, and we noticed several nice animals. The awards in the Long-haired department were made, we believe, by Mr. Harrison Weir, while the remainder were taken by Mr. Tegetmeier.

The attendance was good, and we hope the Show has proved in every way the success it deserves to be. The date for the Exhibition was a good one; and in the height of the season many paid to go in and see these Cats and toy Dogs which would probably at any other time have not otherwise have done so.—W.

ACCRINGTON SHOW OF POULTRY, &c.

THE Show of the Accrington Society was held on the 28th ult. The entries were very good in all sections, and some capital birds were shown. In *Game* the cocks were in far better bloom than the hens, and in the first class—viz., that for Reds, we recognised an old acquaintance (the Otley cup bird) in first position. The second also very good. *Dorkings* were not numerous, but were pretty good; and *Cochins* also good and well shown. *Spanish* only five pens, and these very good; the second particularly fine in face, and the cock grand in comb. *Hamburghs* were, as usual, very good and well placed, although the entries were not large, only one pen of Silver-pencils putting in appearance. *Game Bantams* were a good lot, perhaps as good as any section, and being shown singly looked well, the cup going to a Black Red cock which we considered rather large. Any other variety were in pairs, the first going to a pen of Pekins, second to Black, and third to White Rose-combed.

Pigeons were single birds, except the Variety class, which were in pairs. Carrier cocks were a grand class, as also the hens in the first. Blacks were the winners, and in the second a Dun was first, Blue second, and Black third; the Blue an extraordinary bird for the colour. *Pouter* cocks.—First a Black in fine show, second Blue, and third white. In hens the first was a slashing Black in capital trim. Second and third Blues not as well up as the first nor as large, but both good. *Tumblers* only three—first and second Almond, and third Red, Whole-feather. *Dragoons* were about the best classes of the Show if we except the Magpies, which were all noticed. *Cocks.*—First a Blue, second Blue Chequer, and third a Blue, the first most beautifully tinged with black all over the eye cere. *Hens.*—First a Yellow, second a Silver, and third a Blue. A good class. *Barbs.*—First a Black hen which is difficult to beat; second a Black, and third a Red cock, the latter out of condition. In *Jacobins* the winners were Reds. *Antwerps (Short).*—First a Dun, second also, and third Red Chequer; three good birds. Many others too long for the class. *Long-faces.*—Only the winners as they should be. First and second Duns, and third Red Chequer. *Turbits* were a fair class. The first, a Silver, was good all round; second Silver, with splendid head; and third Black, but rather large. There were not many good ones in *English Owls*. The first a moderate Silver; second the best—a Blue, but in moult, and not fit for the show pen. *Nuns* a nice lot.

Rabbits mustered well, but in Lops there were only four. First a Fawn-and-white buck, 23½ by 5, in nice bloom and grand style; second a Blue-and-white doe of high quality, very soft in ear and exquisite in fur, 22½ by 4½; very highly commended a Black-and-white doe, and a Fawn-and-white, 22 by 4½. *Angoras* were, as a whole, one of the best classes ever seen. Surely they have their home in Lancashire. The exquisite fineness of wool, neatness of ear, and general quality would be difficult to surpass. *Himalayans.*—The first a grand one, and the

others moderate. Dutch.—First Black-and-white, about correct in marking, as also the second, Blue; the rest, though good, being somewhat irregular. Silver-Greys a very good class, and all noticed. In the Variety class first was a real good Silver Fawn, and second a Belgian Hare; and in the Selling class first was a Silver-Grey, and second a Himalayan. Only one Lop was good, and that out of condition.

Of *Cats* there were but four, the first being a pretty fair Silver Tabby.

POULTRY.—GAME.—Black or Brown Red.—Cock.—1, W. & A. F. Fenwick. 2, C. W. Brierley. 3, R. Garnett. *Hen.*—1, T. P. Lyon. 2, J. Cock. 3, R. Braithwaite. *Any colour.—Cock.*—1, J. F. Walton. 2, J. A. JUDGES.—Poultry: Mr. R. Teebay, Fulwood, Preston; Mr. S. Fielding, Trentham, Stoke-upon-Trent. **Pigeons, Rabbits, and Cats:** Mr. E. Hutton, Pudsey, Leeds; Mr. W. Sefton, Balacure, Blackburn.

RUGBY SHOW OF PIGEONS, &c.

The fourth annual Show was held at the Workman's Club on Wednesday the 27th ult. The room was rather small, but the specimens so well disposed three tiers high that much space was economised, and the light pretty good in most cases, all being well attended to with food and water; and the Rabbits, with clean hay and green food, were very comfortable, some litters even being sent with their dams.

In *Pigeons* Pouters headed the list, but the pens were too small, and the greatest difficulty was experienced in getting them to show. First, a White cock in grand order, slender in girth, and good in limb; second also White, very good, but not quite in the same show; and third a Blue, good, but somewhat flat and bishop-winged. All the rest being noticed. Carriers, a grand class of eleven. First a Dun cock, a cliniker in all respects; second and third almost equal Blacks. Fantails a wretched lot, if we except the first-prize Blue and second White. In Tumblers, Almonds won all the prizes. First a hen, and second and third cocks. Owls, first a Blue English cock, which would have taken the special but that his face was in moult; second a neat White African; and third a grand Silver English. Turbits good; first Red, second Yellow, and third Blue; the last best in head, but very foul-thighed. Jacobins—first Red, second Yellow, and third Red. Three good ones. In Dragons first was a very extraordinary Yellow, to which section extra was given; second and third Blues. Antwerps a particular good class, and the winners all Red Chequers. The first in all respects a Short-face. In the Variety class first was a good Black Barb, second a Blondinette, and third a Satinette. The Selling class was large and good.

Rabbits were a splendid entry considering the smallness of the prizes, there being 103 in seven open classes, and five in the local one. Lops, all worthy of notice. First and special, a Sooty Fawn doe, fully developed and full of quality; second

of that colour good in all respects, but not so large or good in dewlap; and third a Black doe, large and grand in all points. Many others coming close to the last two in quality and measurement. Dutch a grand class. First a most perfect Black-and-white; second a Silver Fawn, no doubt the Northampton winner, and without a single point in which trimming could improve it; and third a Grey, also nearly correct. Very many others good in all points but noses, which were very uneven in many specimens. All the winners very good in blaze. Himalayans not so good as we expected to find them, though the winners were pretty correct. Silver-Greys were a very even class, but here there is a tendency to mealiness, no doubt consequent on the great inclination to produce Silver Creams, which we always found conducive to that defect, the only ones at all sharp in silvering being the winners. Belgian Hares were good, in grand colour, but short of ticking and lacing on the ear. In the Variety class the Silver Creams were reversed from the Northampton position on account of condition, the third being a good Angora. The first in the Selling class was a young Silver Cream, which must make a good one; second a Black-and-white Dutch; and third, Himalayan.

There were some good well-shown *Cats*, especially of the Short-haired variety.

PIGEONS.—POUTERS.—Cock or Hen.—1, T. W. Swallow. 2, A. P. Byford. 3, S. Baker. *vhc.* W. Nottage. **CARRIERS.—Cock or Hen.**—1 and Special, H. Yardley. 2, T. & A. Stretch. 3, T. Wheeler. *vhc.* J. Chandler. *FANTAILS.—Cock or Hen.*—1, H. Yardley. 2 and 3, Capt. P. Rayner. **TUMBLERS.—Cock or Hen.—1, 2, and 3, H. Yardley. *vhc.* W. Nottage. *G. Webster.* **OWLS.—Cock or Hen.—1, J. Barnes. 2, T. Chambers. 3, T. H. & A. Stretch. *vhc.* A. J. Barnes. **TURBITS.—Cock or Hen.—1, R. Woods. 2, W. Daniels. 3, G. Webster. **JACOBINS.—Cock or Hen.—1, W. Nottage. 2, T. W. Swallow. 3, H. Yardley. *vhc.* J. Kirby. **DRAGONS.—Cock or Hen.—1, Special, and 3, R. Woods. 2, J. Allen. *vhc.* W. Woods. **ANTWERPS.—Cock or Hen.—1, T. Wilson. 2, J. Chandler. 3, Kendrick. *vhc.* C. F. Herrieff. **ANY OTHER VARIETY.—Cock or Hen.—1 and 3, H. Yardley. 2, R. Woods. **SELLING CLASS.—Cock or Hen.—1, W. Nottage. 2, W. Woolley. *un.* 3, J. Chandler. **LOCAL CLASS.—Cock or Hen.—1, Special, and 2, W. Daniels. 3, G. Loverock. *Special.* S. Bromwich.******************

C. Beasley. **SELLING CLASS.—Buck or Doe.—1, Rev. T. C. Beasley. 2, J. Fould. 3, R. Newsom. *vhc.* Rev. T. C. Beasley. *S. Taylor.* *B. Robinson.* **LOCAL CLASS.—Common.—Buck or Doe.—1 and Special, A. G. Price. 2, F. Fryer. 3, W. Saunders.****

CATS.—SHORT-HAIR.—Male or Female.—1 and Special, F. Wright. 2, Mrs. Salmon. 3, H. Aldwinkle. *vhc.* C. Anderson. **LONG-HAIR.—Male or Female.**—1, Hill. 2, Mrs. Cary. **LOCAL CLASS.**—1, W. Saunders. 2, G. Tyrell. 3, E. Knight.

JUDGE.—Mr. E. Hutton, Pudsey, Leeds.

APIARIAN NOTES.

1, I AM sorry to have misunderstood Mr. Hunter's description of the "Root" sectional super, but I think it was not unnatural. Certainly he will not say it was wilful. He has kindly sent me a specimen of one of the sectionals. It is very neatly made, and can be put together in a minute, but it is even smaller than those advocated and sold by Abbott Brothers. Time alone will decide which are the most useful, those or a larger type, as they come into more frequent use.

2, "O. B." seems to think he has made a discovery in finding that "bees remove honey." But who doubted it, or has denied it? What Mr. Pettigrew asserts but has not proved to the satisfaction of his sceptical friends, is that bees "make" honey, gorging and disgorging themselves, and again regorging and disgorging by a double process. That is a very different thing.

3, Since the 25th May matters have considerably improved in my own apiary. Honey is now seen in some hives, even in supers, but still not in any great quantity. Certainly, I never recollect so little honey stored by the 21st of June. Our only chance now lies with the white clover. If that supply fails, this year will be as disastrous as any I can recollect since I began to keep bees in Somersetshire nineteen years ago.

4, I see that return swarms are not uncommon this year. Three instances of such have occurred to myself—one first swarm, and two very strong casts. One of your correspondents has had a like experience.

5, A curious instance of piping several days after swarming has occurred to me quite recently. I should like to know if such experience is common. A cast which swarmed on the 18th of June (a very large one), was distinctly observed to have a piping queen so late as the 23rd. It had been heard on the 21st. This proves conclusively that piping does not proceed only from imprisoned princesses, as used to be stated. The first swarm out of the parent stock somehow lost its queen in the act of swarming. This was one of the swarms that returned home. But only a portion of the swarm so returned; a considerable number of the bees (several thousands, in fact) entered an adjoining hive, which had swarmed some days previously. My belief is, that the queen entered this hive by mistake, and must have been killed, because both the hives were piping some days after, and both sent out casts with young queens. I should state that the

cast above mentioned also returned to the parent hive. I therefore drove out the whole population the same day, thus compelling them to swarm. To make sure that they had a queen, and to diminish risk of failure, I cut out a piece of comb and gave them a royal cell in a super, out of which there issued a queen some hours later in the day. This may explain the piping. Probably both princesses lived together for several days and were aware of each other's existence.—B. & W.

THE UTILISATION OF CONDEMNED STOCKS.

MR. PETTIGREW in his very able article of June 21st, in which he shows how the swarming system with fixed combs may be carried to the highest perfection, makes the following statement:—"If the best of the three hives be selected for a stock, and have the bees of the other two united to it, we obtain for another year a stock hive of surpassing worth and power." This, no doubt, is correct if it be done in the autumn when most of the added bees would survive to the following spring. But is it correct if the bees be driven and added the end of July? Our honey harvest in these parts, as in many others, ends about the 18th of July, which would consequently be the proper time to drive condemned stocks. Would it be any good to unite these to other stocks with a view to strengthening them for the following season? If not, would it be worth while to defer taking the honey of condemned stocks two months later, say the first week in October? Would the strength given to the hives to which they were added compensate for the loss of the honey they would consume during those two months?

This is a very important question, and one on which I should like to have the opinion of others as well as Mr. Pettigrew. Condemned bees in July would, no doubt, answer admirably for building up into stocks by sugar-feeding; but the question is the value of uniting them to other stocks.—O. B.

BEE MANAGEMENT—DRIVING.

For the encouragement of beginners like myself in bee-management I beg to give you an account of my first attempt at "advanced" bee-keeping. I bought in March this year two stocks for £1 and 12s.; the former weighing 32 lbs. hive and board, and the latter 36 lbs. They were both in old straw skeps, small and rotten. On the 25th of May I took an artificial swarm of 4 lbs. of bees from the 12s. hive, and put it into a straw hive 14 by 12. I fed them for a few days, and now (June 25th) the hive is three parts full of comb, and I can see young bees coming out. On the 12th of June, and for two days previous, I heard distinctly three queens piping in the old hive, so I determined to turn a second swarm out. This I did into a common hive, shook them into a 14-inch hive, and then put a ten-bar frame hive on it. Inverted guide comb was fixed to each frame, and after putting a cloth round and drumming awhile I left them all night, but not before I heard princess No. 1 piping in the frame hive; and on going to listen to the old stock I heard that princess No. 2 had been liberated, and that piping was being carried on by two only. Next morning I found the bees had gone into the frame hive, and now nearly all the frames are filled with comb. The bees that were left in the stock remained a few days longer, when I drummed them out, caught the queen, and divided the remainder amongst my other hives.

The other stock hive (cost £1) I tried to swarm artificially on the 26th of May, but the bees all went back; so I tried again on the 31st of May and succeeded, getting a capital swarm, which has more than three-parts filled a 14-by-12 hive. The stock remained for twenty days, and then I turned it out into a similar hive, and now it is working well. So that out of my two stocks I have four good hives in a forward state, and not a bit of old comb. Being near the heather, I shall if all is well get a fair harvest of honey, though I do not intend putting down either of my stocks this autumn, as I want to keep four at least over the winter, and shall content myself with supers and side combs for my honey this season.

My artificial swarming was laughed at by all the bee-cages, but now they see that I am ahead of them they are beginning to see that there is something in it. If my experience should encourage any timid ones I shall be glad. I may say that though I do not use a bee-dress of any description I have not been stung in any "driving" operation, having driven several others besides my own.—R. G., Kendal.

OUR LETTER BOX.

BEES CLUSTERED ON FOOT-BOARD (*J. Smith*).—Bees should not be allowed to hang in clusters for weeks outside their hives, as it is a waste of time. We advise you to swarm them artificially, or give them room by enlarging their hive. Artificial swarming has been often described in our Journal. If you try the artificial mode you will find it is very simple and satisfactory. Blow some smoke from fastian rags into your hive, lift it from its board, and place it on the ground, bottom up; place your swarm hive on it, roll a cloth round the junction of the hives, drum on the bottom (full

hive for four minutes, then place both hives on separate boards some feet or yards on either side of the old stand. This is artificial swarming, and it is a most useful and valuable invention. We are about to swarm some hives in the same way.

MAKING STRAW HIVES (*Novice*).—By examining a straw hive you may learn how they are made. A young gardener in this neighbourhood was anxious to learn how to make them. He took a hive and undid the stitching, bit by bit, from bottom to top. He needed no more teaching, both he and his father became experts in building excellent straw hives. Hives are made of straw stitched with cane or bramble briars. A tube about 5 or 6 inches long and 1 inch wide is used to keep the straw in rolls. The tube is kept full of straight straw by feeding it at one end, and the stitching takes place at the other end. No handy man can fail in making good straw hives after the first trial.

BEES SELF-WILLED—THE SWARM-CATCHER (*Novice*).—When bees swarm naturally they choose a spot beforehand and go there. If they resolve to alight in your neighbour's garden nothing can be done to prevent them, except the adoption of artificial swarming. The American swarm-catcher is used to prevent two swarms coming off at the same time from going together or becoming one. This swarm-catcher is a kind of square sack of thin material, and is placed around the mouth of the hive when the bees begin swarming. They rush pell mell into the sack, and may be hived at convenience; but the mode of artificial swarming which we follow is far better, and can be done with less trouble than the use of the swarm-catcher.

REMARKS.

27th.—Rain in the morning, sunshine after 9.15 A.M., rest of the day fine and bright.

28th.—Fine all day, and much warmer.

29th.—Another fine summer day, much hotter than the day before it.

30th.—Clear bright morning, cloudy at times in the afternoon, a sprinkle of rain in the evening.

1st.—Dull early, rain began at 9 A.M. and fell heavily for some time; after-part of the day very fine and rather less hot.

2nd.—Rather dull, but pleasant from there being a nice breeze, rendering it quite cool at night.

3rd.—Wind rather fresh and pleasant in morning, a few drops of rain about noon; thunder about 4 P.M., and again frequent with lightning between 5 and 6, with a heavy but short shower; very bright and sunny by 6.30, and rain again at 7.30, and tremendous hailstorm from 8.4 to 8.7 P.M., the stones nearly spherical, crystalline, averaging a quarter of an inch in diameter, but some were over three-quarters of an inch in diameter. Leaves very much cut, bedding plants quite disfigured.

No special feature calling for notice except the above-mentioned hailstorm.—G. J. SYMONS.

COVENT GARDEN MARKET.—JULY 4.

TRADE remains quiet at last week's quotations.

From observations taken near London during forty-three years, the average day temperature of the week is 75.3°; and its night temperature 50.6°.

ROSES AS CLIMBERS UNDER GLASS.

UNDER favourable circumstances Roses can be equally as well grown for a time in the open air as under glass; but everyone who has grown a Rose out of doors knows with regret how short a time the blooms remain perfect, and in many instances they never reach that state, as a day's strong wind or a few hours' heavy rain frequently destroys the hopes of would-be exhibitors, and many a Rose-grower has taken refuge in the wind and rain as an excuse for not "getting a place" in the prize list. Roses under glass have none of these adversities to contend with; they open without spot or blemish, and nothing whatever need mar their beauty from first to last.

It is not, however, at the height of the Rose season out of doors, such as the present time, that indoor climbing Roses could be placed advantageously against those out of doors. But there is a time when outdoor Roses are no more ornamental than the bare stakes or walls that support them, when climbing Roses under glass appear in all their glory. In February, March, and April every greenhouse or conservatory may be rendered beautiful to look at and delightful in fragrance by a few climbing Roses. Roses are valued at all times according to their abundance and time of blooming, but if there is one time more than another at which they are justly esteemed it is in the early spring months.

The proper places for Roses under glass are up the rafters, around pillars, and against dead walls, and any other convenient position excepting the entire roof of the house. This affords shade for the plants in summer, but it is unhealthy for them in the spring. I have never seen any Rose shown to greater advantage than when trained right across the rafters in a large house and the branches all bent downwards, with crowds of newly-formed buds, half-opened blooms, and fully-expanded flowers; no other plant is capable of making a display to equal this in loveliness. Hybrid Perpetual Roses are often used as climbers out of doors. I cannot remember seeing them do well under glass. The Roses best adapted for climbing indoors are the Bourbons, Tea-scented, and the Noisettes. Before speaking of varieties, however, I had better start at the beginning of their culture, and let less important matters follow.

To grow Roses to perfection as climbers under glass it is not necessary to have a well-heated house; on the contrary, they thrive excellently in houses where all the heat comes from a brick flue, and this barely sufficient to keep the temperature above the freezing point when there is 10° or 12° of frost. This is a matter worth remembering; and having settled that they will grow luxuriantly in any temperature between 30° and 50°, the roots must next be provided for. It requires some care to establish climbing Roses, but once this is accomplished they will stand like forest trees; and it is worth observing that after this they seldom or never die-off, and when not

restricted the stems often grow to an immense thickness and the branches cover a large space.

No great success will attend growing climbing Roses in pots under glass, but they will do well in large boxes where they cannot be planted in a border or bed. Much the best way of growing them, however, is by planting them out; their roots need not be under glass, for, like Vines, they do well in outside borders, the stems being taken inside through holes in the wall. Each Rose should have space at least 3 feet square and deep, filled with good soil to grow in, and if more than this can be given so much the better. When the ground is not naturally porous 6 inches of broken stones must be placed in before the soil, which may consist of loam and decayed cow dung. When the plants have been in pots previously they may be turned into this at any time of the year; but it is hardly worth while to remove a large tree from the open air under glass with the hopes of having any desired space quickly covered. It is very much the best to begin with small plants with a few shoots about a foot long. It is perfectly surprising the progress these little plants make in a short time. A sprig of *Maréchal Niel* that was planted three or four months ago had one or two small growths about the length of your finger, and it has now strong thick shoots 7 and 8 feet long. During the growing season they require abundance of water, also liquid manure. This remark applies from the time they are planted until the end of their existence.

As to training, it must entirely be regulated by the space there is to cover. In one case it may be desirable to take up one or two stems a long distance, in another instance a crowd of them may be wanted not far from the root; but this much may be said which applies in all cases—never overcrowd the shoots.

Mildew sometimes attack Roses under glass: sulphuring the leaves is a sure cure for this pest. Green fly is the more troublesome. Small houses may be fumigated, but in large houses where there is nothing else wants cleaning it will not pay to do this; and then a never-failing remedy is to dust the affected parts with tobacco powder and let it remain on the leaves for a day or two.

I never saw climbing Roses benefited by being pruned hard or too closely in; it robs them of their gracefulness and chance of blooming profusely. The shoots may be thinned-out or cut-back whenever they are getting out of bounds. There is another object for which climbing Roses may be introduced under glass. Many have to grow Roses simply to supply cut flowers; they do not then need to be trained in a select place in the conservatory, but be planted in any out-of-the-way houses where there is room for them.

Respecting varieties best adapted for the work, I do not think there ever will be a Rose raised to equal, far less surpass, *Maréchal Niel*. In depreciation of a sameness in an old-fashioned flower garden Pope says—

"Grove nods to grove; each alley has its brother;
One half the garden just reflects the other;"

but I do not think any person would ever have cause to

complain of the *Maréchal* being "same," although both sides of two or three span-roofed houses might be covered with it on the roof. I have known some people to have had thousands of blooms of it out at the same time, but I never yet heard a word about there being too many. It is asserted that it does not do well or live long on the *Manetti* stock. I know it does capably on its own roots.

Other good *Roses* in the same class for climbing indoors are *Céline Forestier*, canary yellow, fine form; *Madame Caroline Kuster*, light lemon; *Jaune Desprez*, pink; *Aimée Vibert*, pure white; *Cloth of Gold* is an effective name, but that, as a rule, is the best of it. When used in a cut state all these *Roses* should be cut by the time they are half open. Another *Rose* worthy of a place next the *Maréchal* is *Gloire de Dijon*. It grows and blooms freely, and its buff-orange flowers are of great substance. This is a Tea-scented *Rose*; and amongst these there are some lovely *Roses* for climbing, I will only name a few. *Clotilde*, white and pink; *Madame Falcot*, rich orange; *Perle de Lyon*, nearly as good in colour as *Maréchal Niel*, but not so free in growth; *Marie Van Houtte*, white; *Madame Margottin*, beautiful yellow and pink; *Devoniensis* is superb in the bud, but the blooms are not produced freely enough to warrant its being recommended.

Those who have climbing *Roses* under glass should now keep them clean and train the shoots thinly; for it is by good attention given at this period of the year that blooms—some gorgeous, some lovely—are eventually produced.—J. MUIR.

WATER.

THE gardener who hath a full supply of water and ample means for its distribution among his parched crops in this hot weather is a man in the enjoyment of great privileges; let him be thankful and murmur not because he lacketh other things which are as trifles in comparison. Do you not agree with me, brother blue-aprons? and is not the very sight of my title refreshing in this droughty time, to say nothing of the copious supply of the precious fluid itself, which I most heartily wish was at the disposal of every one of you? for I am well aware from dearly-bought experience how badly many gardens are supplied with water; and it is with an earnest wish to assist those who may be now having to contend with the difficulties arising from such an unsatisfactory state that I now refer to the subject.

To promote that free, strong, succulent growth in vegetables which is so desirable it is necessary that the soil be moist as well as rich—a condition of things which it is often difficult to maintain during a period of drought, moisture then escaping from the soil by evaporation with such rapidity that a crop may be spoilt, if not lost outright, through a few days' inattention to what is going on, and neglect in the prompt application of the most simple remedy of all—plenty of water. There is, however, something very unsatisfactory in this constant pouring-on of water—this daily contest with the drought, the surface of the soil becoming so washed and hardened that soon the water will not enter freely until the soil has been broken up or stirred with hoes. To meet this difficulty and in a great measure overcome it, the first good drenching with water should be followed immediately by a surface-dressing of rough leaf soil, old hotbed or any half-decayed manure, which tends so materially to check evaporation, that a weekly, or even a fortnightly, watering does more good than the daily one without surface-dressing, for the palpable reason that no hitch occurs in the food supply of the crop, the moisture-laden soil promoting that steady process of decay in the manures stored up in it, and the absorption of the fertilising gases, which are thus constantly permeating the soil: hence arises a free strong growth and a full and perfect development of tuber, root, fruit, flower, or seed—whatever property for which each crop is cultivated for is obtained; the truest economy of time and labour exemplified, and, best of all, the glorious summer weather is turned to full account instead of being wasted or suffered to destroy those crops to which it is so truly beneficial when supplemented by skilful and timely culture.

However carefully and well water may be applied a large quantity is quite certain to be wanted in every garden during summer; prompt measures should therefore be taken to remedy any deficiency in the supply. Storage must be resorted to if there is no such perennial source as a spring on a higher level than the garden, or a hydraulic ram throwing up water from a valley. A garden that is unprovided with some such means of combating the evils attendant upon a hot dry season may

fairly be termed quite behind the age, and in such instances it is certainly most unfair, to say the least, to expect either fruit, vegetables, or flowers in perfection.

No doubt there are hundreds of gardens having neither an elevated spring nor a stream in a valley near them, but I quite fail to see why any one of them should be without an abundant supply of rain water accumulated during autumn, winter, and spring in ponds or tanks—ponds being altogether preferable, as they are less expensive, and the water is fully exposed to sun and air. If I am asked how the ponds are to be filled, a variety of ways immediately present themselves to the mind. The house itself and every outbuilding should have shooting and gutters to convey the rainfall to drains, such drains being carried under walks having gratings and connections at the sides. Then, too, the very land itself may be drained and the main drains made to empty into a pond. And remember that pond-making is not an expensive affair, even when done upon a dead level; for by turning the soil which we excavate to account for raising the sides the required depth is soon reached, the most expensive part of the business being the puddling, which it is usually necessary to do in order to prevent waste from soakage through the sides and bottom.

To raise the water thus accumulated to a higher level a force-pump will be necessary. I have used a cheap and simple form of pump for sewage very successfully for the last three years, and hope soon to give a sketch of its fittings; but I may now say that with it one man can with two strokes draw up the sewage from a depth of 10 feet and force it through some 200 feet of piping to an elevation of 25 feet, and as the specific gravity of sewage must be considerably greater than that of clear water a similar apparatus could of course be used for the latter. When such a pump is used let it always be placed immediately over a cistern or close by the pond, so as to force the water through the greater length of piping, and to draw it through such a short length only as is necessary to reach nearly to the pond bottom.—EDWARD LUCKHURST.

THE DEGENERATION OF ROSES.

THE question as to the degeneration of *Roses* is one that requires much consideration before you can come to any definite conclusion about it, and most people have been too busy lately in their gardens to spare time for the contemplative part of horticulture. In the first place, is it admitted as a fact that the *Roses* mentioned have degenerated? If they have, it might be possible to account for it in other ways than those suggested by your able correspondent "*HEREFORDSHIRE INCUMBENT*." Many of them are grown in small holes at the edges of lawns, which never suits them well (if *Roses* are wanted at the edges of lawns there ought to be a narrow continuous bed of earth), and others are perhaps over-stimulated in their earlier years. In either case the buds propagated would be liable to degenerate. With regard to *Géant des Batailles*, I think it has been surpassed by the newer varieties. I have looked over Mr. Darwin's interesting remarks on bud variation in his "*Plants and Animals under Domestication*," but have not been able to find any allusion to the propagation of the *Rose* by budding on the *Briar* stock as a cause of degeneration. It may be in some other work. He says a great deal about the necessity of changing seed and procuring plants from other places to prevent their degenerating, and I have experienced the same thing with regard to *Strawberries* propagated from runners. I can quite understand the *Rose* suffering if propagated for a long time from buds grown in the same garden, particularly if not a suitable soil; but if grown with proper care and a change of buds procured occasionally I think there is a very long lease of life before most of our favourites. I think the propagation of *Roses* by budding is not a parallel case to the propagation of plants by self-fertilisation; in the former case you have a continual change of stock, and as the bud grows it is merely an extension of a former growth. It may be influenced for good or evil by the previous stocks by means of which its life has been extended, but most likely not in the same way as a self-fertilised plant. Some of our Apples have been propagated by grafts for hundreds of years, and are as good as ever they were. It is true Knight thought there was a limit to their duration, and that some of them had nearly reached that limit; but other authorities, amongst whom I believe was Mr. Rivers, had doubts on the subject, and seemed to think their career might be almost indefinitely prolonged, and I am rather inclined to take that view of the *Rose*.

In looking through Mr. Darwin's book before mentioned two or three years ago a valuable idea occurred to me with regard to budding the Rose. I have frequently been annoyed in looking over the Rose trees to find some that throw up a lot of blooms crowded together almost as bad as the hen-and-chickens Daisy, and Madame Boll was a great offender in that way. Sometimes you could scarcely find a single Rose to gather. "Why not cut them off?" suggested a friend, but I could never make up my mind which buds to cut off; so they all remained, and sometimes were so crowded together that they never could bloom properly. There was occasionally a shoot with a single bloom, and the idea occurred to me that if buds were taken from that shoot and propagated the evil would be remedied; instead of which, by cutting off the single blooms and leaving only the other shoots to bud from, the objectionable features were extended by a species of non-natural selection and the survival of the least fit. I have had a few Roses budded in the way suggested, and there certainly is an improvement in the right direction, but I have not gone far enough yet to warrant it as a cure, and intended to continue the experiment this year and let you know the result in the Journal; but as it would be two years longer before I could say much about the result I give your readers the benefit of the idea now, and hope it will prove of service to them.—AMATEUR, Cirencester.

FORCING VIOLETS.

VIOLETS do not force well, for they delight in coolness, moisture, and air. Any approach to a close atmosphere or a high and dry temperature is fatal. In a house, however, kept at a moderate temperature, the plants will, if placed near the glass and well ventilated, afford a quantity of their fragrant flowers with certainty in winter and spring. To have Violets during those seasons preparations must begin early, and that is why I allude to the subject now. In growing Violets in pots there is more than one way of doing it. We may pot the rooted runners or suckers in early summer, be at much trouble in watering them and taking off runners, and after all have a harvest of leaves only; or we may pot in late summer plants with poor crowns, having suffered from drought and its concomitant red spider, and also fail; and we may introduce plants with the best of crowns to a warm and close atmosphere and fail again. My failures in growing Violets in pots were formerly signal, but now my efforts are successful. Bunches of flowers were at command from cold pits from October to April inclusive. Very welcome are bunches of Violets, but some like to see the flowers upon the plants, and the plants grown in pots. What more acceptable than a stand having a panful of Lily of the Valley in the centre, and blue sweet Violets surrounding? Well-bloomed plants of Violets in pots are always appreciated, and to obtain them is one of the simplest practices in horticulture.

Violets in pots are grown in two ways—namely, as single specimens and in masses. Single specimens are had by planting even now rooted runners or suckers in an open situation, watering copiously in dry weather, and keeping free of weeds and runners. In September we lift the plants carefully and pot in 7-inch pots, though 8-inch pots are not too large for well-developed crowns. The pots must be efficiently drained with one flat crock and about an inch depth of charcoal. Sound loam one-half, a quarter of old cow dung, and a quarter of leaf soil well mixed together forms a good compost. It is no use huddling the roots into a heap in the centre of the pot and cramming the soil around them, but work it in among the roots and make moderately firm. Give a good watering, and place on ashes in a cold frame. Shade from bright sun, and keep rather close for a week or ten days, and then admit air freely day and night except in frosty weather. Remove the old leaves as they turn yellow, and any time after the middle of October the plants may be moved to a shelf in a light house, and if air be passing over them they will flower freely. The temperature must not exceed 50° by day from fire heat. Any cool house from which frost is excluded will answer admirably, air being plentifully admitted in mild weather. The plants will require to be kept well supplied with water and liquid manure. The best that can be given is soot water, one peck to thirty gallons of water, which may be given at every alternate watering. Soot water is not only a valuable stimulant for the plants, but is a preventive of red spider.

Such kinds as Czar and Victoria Regina will require 7 or 8-inch pots, but small growers such as Queen will do in 6-inch,

whilst Neapolitan and its vars. New York, Marie Louise, &c., will do well in 5-inch pots, and the Double Russian and its vars. King and Double Red (*Viola suavis rubra flore-pleno*), one of the best for pots, will succeed in 4 or 5-inch pots. The very finest of all the singles is Victoria Regina. I make mention of those only in commerce, for it is surpassed by Prince Consort, and if a white single companion be wanted there is none equal to White Czar. These are the earliest, commencing blooming with certainty in October; and a double to come in at the same time is New York with the true Neapolitan. All the others will not flower until after Christmas, but they may be had somewhat earlier by forwarding them in the gentle temperature above named. It is well, however, to keep them in frames until well advanced for flowering. They should be kept in the frames until drafted into the house for flowering. I may mention Blandiana as a fine double Violet and a continuous bloomer, also Devoniansis, blue, single variety, very sweet.

The next mode of growing Violets in pots may be an old practice. I gained the hint from some pots received from Paris. The pots were crammed with crowns not more than an inch apart, and the condition of their roots lead to the conclusion that they had only recently been "done up." They were, in fact, neither more nor less than rooted runners, such as Mr. Lee told us in this Journal how to manage in order to raise-up a stock and bring-out their floriferous character. Now, instead of cutting-off the runners as advised for specimens, permit them to grow until they commence forming a crown at their extremity, then take out a little soil and lay the wire for 2 or 3 inches of its length next the crown, leaving that or the extremity of the runner above ground, and secure with a peg. The runners are left on the parents until the middle of September, when they are carefully taken up and potted. Place the rooted runners an inch apart all around the inside of the rim of the pot, and then fill-in the centre, working the soil well among the roots, all crowns being placed on a level and just above the soil. A 6-inch pot will not hold more than a dozen crowns of such kinds as Victoria Regina, whilst it will accommodate two dozen of Neapolitan vars. and *V. suavis* vars. They must not be potted "hard;" the right mode is to fill-up the interstices just close—no more, for we want the roots to run and to allow water to percolate freely through the mass. If placed in a frame, and kept close and shaded from sun for a week or ten days, they will soon be established. If the weather be moist it answers to place the pots on ashes at the north side of a low wall or fence for about a fortnight, but they are best in a frame. When rightly managed nothing can exceed these masses in the freshness of their foliage with the flowers peering above it, or the buds peeping from it in modest beauty. The one great point to be aimed at is not to allow the crowns before potting to be crowded, they want air and light. They must also be kept free from red spider; the foundation of having Violets in spring is giving good attention to the plants in summer—now.—G. ABBEY.

THE AIR-TIGHT VINERY.

THIS vinery was invented to supersede the ground vinery, with which I was never satisfied. It is pleasanter to walk through an avenue of Vines than to look upon them on the ground; besides, it is easier to prune the Vines and thin the bunches. There is no fear of mildew, and the economy of surface considerably greater; but the most important thing of all is that the Grapes are thoroughly ripened early in the season, and the building constructed at half the expense. My vinery has been built about eight years. It is a regular sun trap, the temperature on hot days being often over 100°. The principle is not to let in any external air; once a-day the path and borders are watered. A leaf is never scorched.—OBSERVER.

RICHARDIA ÆTHIOPICA.

I HAVE had the *Richardia* growing and flowering most freely for more than ten years in a small cemented tank about 8 feet in diameter in my garden. When I first made the tank I placed a depth of 1 foot of common garden earth at the bottom, planted in it a small clump of *Richardia*, and filled the pond to the depth of 2 feet of water above the earth. The next year I was given a large clump of *Richardia* which had been growing in a border and not flowering well. This clump I divided into two, and threw the pieces into the pond or tank. I have never

given them the least care. The tank is frozen over nearly every winter, sometimes for a fortnight at a time, but the *Richardias* have increased till they have nearly filled the tank, and at this present time I can count nearly forty blooms open, very large and fine in colour and shape. Last year and for many years I have had nearly the same number, and the seeds ripen and seedling plants are plentiful.—C. BEAUMONT, *Tenby*.

THE COMMERCIAL VALUE OF THE ROSE.

ONE of the most marvellous features in the history of the Rose is its commanding influence—the power it has of attracting to itself the notice of almost all classes in this country. As a result of this magnet-like influence which the Rose possesses and exerts, an industry of considerable, even surprising, magnitude has become established. It will not be exceeding the bounds of truth to say that no other flower commands the attention and exercises the powerfully attractive force that the Rose does, simply because no other flower possesses in combination the same qualities of variety, beauty, fragrance, and hardness.

The Rose is the floral emblem of this country. When and by whom it was installed in that prominent position I know not; but this I know, that it is worthy of the country, and I think also the country is worthy of the Rose. Its right as England's emblem is unquestioned, its position undisputed, and its qualities are admitted—in a word, it is the national flower and receives the nation's homage.

That this is so is evident by the extensive commerce in Roses, so extensive as to reach into almost every village and hamlet in the land, and which is spreading not only to other nations of Europe, but which has bridged the mighty Atlantic and gained a footing where it has a right to be, among England's sons on American soil. The export trade in Roses has long been great in France, and now a similar trade is great and growing greatly in England.

What is the inquiry that arises in the minds of visitors to the Rose-growing nurseries of England during the autumn months? Is it not, Whence do all the Briars come? whither do all the Roses go? This twin question is a very natural one, for no one can note the thousands, even hundreds of thousands, of Roses which are annually provided without some feeling of curiosity being evoked and inquiry expressed as to their probable destination. The trade in Roses in England is indeed a mighty trade; how great is not known. Examples of its magnitude might be quoted; approximate numbers of the Roses annually raised by the great Rose-growers—the specialists—might be given. This, however, would be obviously undesirable, especially as it is not necessary to do so. A sufficient instance of the extent to which Roses are grown is gathered from the practice of a firm who are not Rose specialists, and who yet annually bud sixty thousand Briars and as many *Manetti* stocks, and in addition purchase many more Roses to meet the demand of their customers. There are trade rosarians who prepare thrice that number of Roses, and not only prepare them but sell them. So great was the demand for Roses last autumn and winter that it was only by giving early orders that purchasers could secure what they wanted—good plants of particular varieties. One well-known nurseryman, conceiving himself overstocked last autumn, sold five thousand standards to a brother in the trade, and before the planting season was over the vendor had to purchase seven thousand at an enhanced price to execute the orders which steadily poured in. Another nurseryman, on being asked the question why he did not advertise his stock, gave as a reply that he dare not do so, as he had orders for one hundred thousand Roses on his books while the leaves were yet green on the trees. Those are instances which suggest something of the extent of the commercial value of Roses. The annual sale of Roses in England is to be counted not merely by thousands but by hundreds of thousands. There is little or no danger of exaggerating in stating that the aggregate number of Roses yearly propagated in England exceeds a million—that is, Roses propagated for sale. It is more likely that three millions are nearer the mark, since more than one grower has to be credited with five hundred thousand. There are also many thousands of plants imported annually from France. Thus the Rose trade is a great industry, wherein thousands of pounds are invested, in which hundreds of persons are employed, and to which a great extent of land is devoted.

The amount of capital invested in land alone for the cultivation of Roses would be startling by its magnitude were it

possible to ascertain the sum total. Land selected is of the best—the most valuable—land that is capable of growing food in the greatest quantity and of the best quality, but it pays better to grow Roses. Is there any stern utilitarian who thinks it is a mistake and a pity that land capable of producing wholesome indispensable food should be devoted to the production of a flower? Well, it is not a mistake. The land that grows the greatest amount of money is the most profitable to the nation, for money is condensed food—condensed everything that is requisite for a country's population. A considerable amount of money derived from the culture of Roses is expended in labour—in the employment of skilled workers and ordinary labourers. Whole families are thus directly supported by the Rose—families which are certainly numbered by hundreds and almost as certainly by thousands. It is the land occupied by Roses that grows the food for these thousands as surely as if the food were gathered by the consumers of it from the ground producing the Roses. We sometimes hear it said by those who have little or no perception of beauty, who possess no sentiment, but who live in a little matter-of-fact world of their own, circumscribed by the cold bare walls of prejudice, that there is "no good" in growing flowers and in establishing and promoting flower shows. Let the great and respectable portion of the community who derive their livelihood from the industry of flower-growing and its correlative flower-showing answer that question. The answer is convincing, and in itself unanswerable, that as there is "beauty in utility," so also there is utility in beauty. Thus flowers have a use, a matter-of-fact substantial use, and no one flower is more "useful"—the word is used advisedly—than the Rose.

The cultivation of the Rose is commendable apart from the utilitarian aspect of the question. Rose-growing affords congenial exercise for the educated and refined, and those who are in a lesser degree educated and refined enter a school from which they will learn much that is good when they enter the school of the Rose. It has been said that the songs of a nation exercise an influence equal to the nation's laws, and that the pleasures of a nation—the mode of recreation of a people—is only a degree less important than its industry. In that there is truth. The real character of a nation is better and more truthfully ascertained from the manner in which it plays than from the way in which it works. Work as such is in its nature arbitrary, compulsory; recreation is voluntary, natural. It is a hopeful sign, therefore, when the pleasures of a great portion of the community consist largely in the cultivation of flowers. An engagement—a voluntary and ardent engagement, in such a pursuit shows those who indulge in it in their true colours, and tells in a manner which cannot be mistaken of their peace-loving industrial character. The work of those whose recreation is pure and salutary becomes additionally cheerful, and cheerful work is profitable work. England on a memorable occasion was once referred to reproachfully as a "nation of shopkeepers," but it was the peaceful industrial shopkeepers who broke a tyrant's power and laid a war king low. A band of soldiers was once regarded as being feminine, their recreation was not of that coarser kind where the intellect plays but a minor part; but it was the "milk-and-water" contingent, the noble band of a noble leader—Havelock, who in the hour of England's need preserved the brightest jewel in our monarch's crown.

Let, then, the recreation of flower culture pursue its onward course, and let the industry of flowers—of the Rose as the national flower—increase and its shows flourish. Let all who can do so aid in this work, for the nature of it is good, and the results will be beneficial. Let Rose-growing as a trade—an industry—expand, for on its prosperity depends in a great measure the well-being and the domestic comfort of hundreds of humble workers who are engaged in it, and who are indebted to it for their daily bread. Let amateur growers of Roses increase, and Rose shows prosper. Why do those growers cultivate Roses? Because the occupation affords them pleasure—wholesome healthy pleasure—and the blooms add happiness to many happy homes, and gladden distant friends—it may be sufferers in some hospital ward. Why do such growers exhibit their Roses? Is it for gain? No. There can be no gain, no money gain, in travelling hundreds of miles by night and by day conveying their treasures to the exhibition tent or hall to win a chance honour. But there is a gain—a coveted, a cherished reward—of having afforded others the means of sharing the gratification of the growers in enjoying the magnificent blooms. Is not a pursuit so unselfish, so commendable, worthy of support? Are not Rose shows deserving of

success? Does not the industry of the Rose merit prosperity? Nine-tenths of the readers of the *Journal of Horticulture* will answer, "Yes;" and I know, for I have the best means of knowing, that the Editors give a similar and emphatic answer.

Rose shows have done much and are capable of doing more in increasing the industry of our national flower. An unity of effort and an organisation of strength are only required to achieve success. The National Rose Society affords the opportunity of much good being done in widening a source of pleasure and in increasing an important branch of trade. To what extent and in what manner the position may be improved depends on the support that is given to local societies and to the national head. Certainly the central Society is capable of giving a great impetus to Rose culture, and it ought to be placed in a position to provide two shows a-year, and to give at least two medals annually as prizes of honour to be won by members of affiliated societies. The intrinsic value might not be great, but the honour of winning the Society's medal could hardly fail to be appreciated, and the more perfect and extensive cultivation of the national flower would be thereby stimulated.—J. WRIGHT.

ASPASIA VARIEGATA.

THE name of *Aspasia* is derived from *Aspazomai*, I embrace, the labellum partly embracing the column of the flower.

Fig. 12.—*Aspasia variegata*.

It is a native of the tropical part of South America. Dr. Lindley received specimens of it for the first time from Mr. Joseph Knight of the King's Road in February, 1836, and subsequently from Mr. Bateman. The flowers are deliciously sweet in the morning.

Mr. B. S. Williams states in the last edition of the "Orchid-Grower's Manual," that *Aspasia lineata superba* bloomed with him last year, and he describes it as being very beautiful. The *Aspasias* are dwarf-growing Orchids of easy culture.

MOUTAN OR TREE PÆONY.

We are indebted to China for the Tree Pæony, from whence it was introduced in 1789. There are now many varieties of this commanding flower. Sometimes in the spring I have

known the young growth and flower buds killed by the frost, and to ensure good flowers they should have protection or a very sheltered situation. They have a grand effect against a wall, where they are easily protected by mats or branches of fir; but to have them in perfection they should be grown under glass. They may be either planted-out or kept in pots. They are termed hardy shrubs, but they are well adapted for indoor work, and with care and very gentle forcing they are useful for conservatory and other decoration in early spring. Among the best of these Pæonies are *Pæonia rosea semi-plena*, *P. Banksii*, *P. carnea plena*, *P. albida plena*, *P. globosa*, and *P. atropurpurea*. They thrive in good loam, peat, leaf soil, and grit. They require thorough drainage when in free growth with a good supply of water, and are all the better for weak liquid manure water. After flowering they should be plunged in ashes in a rather shaded place. They are increased by cuttings under glass, but I find the best mode of increasing them is by layering. They are great favourites with us, and are worthy of more extensive cultivation.—A. N.

THE WEST OF ENGLAND ROSE SHOW.

HEREFORD, JULY 6TH.

THE eleventh Exhibition of this popular and, comparatively with others, venerable Rose Show, offering for open competition nearly £200, was held at the above date in the Shire Hall of the ancient city of Hereford. The building, all exhibitors and visitors will allow, is exceedingly well adapted for the purpose both from the shape and size of its hall, the airiness and convenience of its corridor, side rooms, and vestibule, supplemented for the occasion by a tent for dressing, and last, but decidedly not least, for the glorious flood of light it becomingly sheds down upon the varied hues of the legion-named family of the queen of flowers. More than once, I may add, has "WYLD SAVAGE" affectionately alluded to this effect in the columns of "our Journal."

The number of exhibitors was not up to the standard of last year, when almost every available inch of space had to be utilised; nevertheless, the Exhibition was generally allowed to be of unusual excellence. Many first-rate judges, indeed, who were present expressed their admiration, and gave their opinion that—whether for form, smoothness or size, colour or freshness—they had never seen Roses surpassed, whether in the nursery-men's or amateurs' division. Doubtless the late warm thunderstorms had much to do in removing the charge of irregularity and a certain coarseness under which blooms have as a rule to a short time ago only too apparently laboured—a marked and unfortunately only too true characteristic of the season when late frosts and cold nights have unpropitiously heralded in the summer, leaving ill-conditioned results in mildewed and abortive buds, except in some exceptionally favoured districts ineradicable and permanent.

The most interesting feature of the Exhibition was the meeting of Mr. Baker of Exeter, the hero of a hundred fights and holder of countless cups, and the new favourite of Dame Fortune, Mr. Jowitt of Hereford, the Rose-garlanded victor of Wednesday's well-foughten field in St. James's Hall. Too much praise cannot be awarded to Mr. Baker, who richly deserves his *nom de plume* of "Hercules" for his prowess in retrieving his despoiled laurels against so powerful an adversary as Mr. Jowitt, meeting him as he did at home quarters on his own vantage ground, although it is only fair to add that stress of weather at a critical period militated doubtless against that gentleman's success, as safe-travelling his grand Roses is one of his many strong points and secrets of success.

In the open nurserymen's division, Class 1, seventy-two single trusses, in which £35 were offered for competition, and out of which Herefordshire nurserymen were excluded, Mr. Cant of Colchester, *mirabile dictu*, was the only competitor, but happily that Rose giant was a host in himself—equal to the occasion and worthy of his high reputation. Mr. Cant's exhibit, which was a feast of Roses indeed, contained marvellous blooms, among others almost equally good, of Horace Vernet; Reynolds Hole, not up to the mark generally (unlike its worthy prototype) this season; Triomphe de France, a large flat Rose, which, although strangely the premier seedling in its native country, has already outlived its early fame, though as a charmingly sweet and free-flowering variety it will be useful in the garden; Hippolyte Jamain; Tea Madame Hippolyte Jamain, a Rose not to be confounded with the good light Hybrid Perpetual of the same name, and like it seemingly a promising variety; Louise de Peyronny, Mrs. Baker, very charming indeed, and well deserving "WYLD SAVAGE's" encomiums.

In the open class, seventy-two distinct varieties; first prize Messrs. Cranston & Co. This was a very grand exhibit, and very hard it is to particularise. Attention may be called to Elie Morel; François Michelon, finely exhibited everywhere this season; Duke of Edinburgh; Sir Garnet Wolseley, a new Rose

raised by the exhibitor, well keeping up its reputation, and finely shown here and at the National; Mons. Etienne Levet, one of the most attractive and certain exhibition Roses catalogued; Marie Cointet, a Rose so good as a traveller and effective as to be indispensable to the exhibitor; Madame Lacharme, exhibited so lovely as to disarm those few wavering in allegiance; Mons. E. Y. Teas, one of the greatest acquisitions lately; Prince Camille de Rohan, superb both in size and depth of colour, but likely to be left in the background by La Rosière, a new dark Rose, equally rich and dark in colour, and of fine substance and better habit; and Général Jacqueminot, an old Rose that happily goes far to prove against the deteriorating theory, so grandly has it been shown this season.

Teas and Noisettes constituted a small but beautiful class. Again at Hereford, as at the "National," Mr. Cant was an easy winner. Especially lovely were Souvenir d'Elise, a perfect gem; President and Souvenir d'un Ami, choicest gifts of Nature assisted by art, to dream over and enjoy, if never to expect to grow them like the Colchester chief. This class, though smaller, was far superior in quality to the National.

Among the new Roses exhibited in a special class (H.P. La Rosière has been already mentioned) two only deserve special mention. H.P. Madame Prosper Langier, a well-shaped clear carmine Rose of good size, well shown by Messrs. Davison, and promises to be an acquisition; and H.P. Abel Carrière, a new Rose of fine dark colour and good shape, indifferently shown here, but useful if it improves in form, staged by Messrs. Curtis of Torquay.

In the amateurs' open division, thirty-six varieties, single blooms, winner to hold Messrs. Cranston & Co.'s £15 15s. challenge cup, first prize R. Baker, Esq. In Mr. Baker's faultless stand were the following superb blooms, the *crème de la crème* of Rose cultivation:—Camille Bernardin, an exquisite bloom; Marquise de Mortemart, exhibited as the fragile variety very rarely is both in single and treble classes, where, by-the-by, Messrs. Baker and Jowitt held the same relative positions. Xavier Olibo was exhibited in great substance and strong habit. How can this variety be called by an authority in the Journal as weak and dwarf? Charles Lefebvre was staged worthy of the variety; Marquise de Castellane, a perfect model of a fine smooth Rose; Lord Macaulay, a splendid specimen of this shy dwarf variety; and Monsieur Boncenne, of rare colour and substance—the best dark useful Rose. In Mr. Jowitt's stand specially fine were Madame Fortado, a speciality of Herefordshire, almost discarded as incorrigible elsewhere, but an early exquisitely sweet Rose; where it takes it is a pleasure. Baronne de Rothschild, very grand; Madame Hippolyte Jamain, a most superb bloom; Maréchal Vaillant, splendid bloom of this old useful Rose; and Mlle. Marie Finger.

In the division restricted to Herefordshire Miss Bulmer's (Broadlands, Hereford) stand of twelve trebles was the theme of general admiration, whether for the size and quality of the blooms or the excellence displayed in their setting-up—an accomplishment amateurs in general fail in. This lady took in style all the first prizes offered in this class. Mr. Arkwright, Hampton Court, Leominster, was an easy winner with grand blooms of Maréchal Niel. Many of your readers will remember he carried off the same honours in St. James's Hall. This gentleman exhibited a bloom of this variety in his stand of thirty-six so enormous and still so perfect that it certainly ranked as the premier bloom in the Exhibition, though, as may be supposed, dwarfing the proportions of his other blooms.

In Class 1, the floral art division, there was an artistic display of dinner and drawing-room decorations (the latter special prize presented by Lord Bute) far eclipsing all previous efforts in this direction, and pronounced worthy of comparison with the best exhibitions ever held in London or the provinces. Mr. Joseph Pulley, Lower Eaton, Hereford, was awarded Lord Bute's prize; and the Hon. and Rev. J. T. Boscawen, who was Judge in this division, complimented Mr. Pulley's gardener, by whom the decoration was made, upon its being the most simple and yet artistic and novel design of the description he had ever seen—a centre piece and four corner pieces of ordinary glass; but the pleasing effect caused by the happy arrangement of Adiantum Farleyense of different shades and some Grasses, with just a sprig of Spiræa or so, was perfectly indescribable.

The day being stormy no doubt kept many from a distance away; but the one drawback to the perfect success of the Exhibition was the absence of the Rev. J. B. M. Camm, who by missing his train deprived our western Show of his valuable assistance as one of its Judges and exhibitors, and the public of the interesting description that would have appeared in the columns of the Journal, now hurried over late on Saturday by—THE HEREFORDSHIRE INCUMBENT.

PACKING.

THE packing of fruits, flowers, and vegetables takes up no inconsiderable amount of the gardener's time and attention in most large establishments during what is termed the London

season, and as that season unfortunately includes the season of cropping, "bedding-out," Grape-thinning, and many other things which take up a great amount of time, and cannot be postponed a day beyond their proper time without increasing the labour, it is doubly necessary at this season to economise time and to prevent confusion.

When I first commenced packing here there was but little to pack, and beyond a few boxes and hampers of various sizes stuck about in corners wherever there happened to be room for one, little was kept in stock for the purpose. Now the work has gone on growing till last month no fewer than 133 packages were despatched, and it is still increasing, so that it became necessary to introduce some sort of system. Before we did so scenes of confusion were not uncommon; a box of a particular size might be wanted immediately, and any size but that of course was at hand, or having found the size required it would be minus a lid, and in the hurry a good hand-saw being a little too convenient, a little piece would, perhaps, be sawn off another lid to make it fit, and thereby create for ourselves the same difficulty to be got over another time. Boxes, too, did not always find their way home when there was no check on them, and when one loses a box there is sometimes a lurking suspicion that something else is lost with it. Besides, everyone knows who has had to pack in a makeshift sort of way, that hammers and pincers have a habit of disappearing just when they are wanted, nails of running short when we thought there were plenty; string, labels, paper, wadding, &c., ditto. The remedy for all this is the packing-shed and packing-book. A shed which I have had fitted-up for the purpose, and which also answers the purpose of office and store-shed, is on the north side of a wall, and measures about 36 feet by 10 feet 6 inches. It has a bench on the north or front side 3 feet wide on which the work is done, and another at the back 2 feet 6 inches wide, leaving a walk of 5 feet in the centre, which is none too much when several people are at work and there is a good deal of passing.

Hampers are numbered 1 to 15, boxes 1 to 66, and their sizes are known by their numbers; for instance, 1 to 20 are flower-boxes all of one length and breadth outside, the lid of one fitting any of them. Another series is for Peaches, Nectarines, and Grapes, varying in depth but not in length and breadth. Strawberry-boxes are another size, and these three measurements answer the purpose for almost everything. They are so distinct in size and appearance, and there being only three or four sizes of lids there is no time lost in hunting them up and fitting them. I have tried boxes with hinges and fastenings; but as both hinges and fastenings soon come to grief, I have long since gone back to loose lids and $1\frac{1}{2}$ -inch brads, and I find they last as long as any and are most convenient.

The packing-book is the next consideration. In this every box and every hamper is marked down as it leaves and as it returns. On the left-hand page under the heading, "packages despatched," are the following items to be filled-in by the packer—viz., date, destination, description, contents, numbers, remarks; and on the opposite page under heading of "empties returned," are date, from whence, description, numbers, condition, and remarks. I find these forms and figures have a wonderful power to bring the packages back and keep them in place. Of course they often come back broken, but that I fear is out of my control. Stock is taken at intervals to see that nothing is short when likely to be required. I hope in a future paper to say something about the way packing is done.—WILLIAM TAYLOR.

BURGHLEY YELLOW ROSE.

In your notice of the Royal Horticultural Society's meeting of July 3rd a Rose called Burghley Yellow is spoken of. I have known the Burghley Yellow for the last forty years. It is the double yellow Provence. It was brought originally to Burghley House, the seat of the Marquis of Exeter, by a French cook. I have also seen it growing in a semi-wild state at Bologna. It is a most difficult Rose to bloom, but of great beauty when the buds will open. I know no such yellow. Mr. George Paul of Cheshunt informs me they are unable to grow it there. I have several times budded it on the Briar. It is known in Lincolnshire, and is grown at this time in great perfection at Enham Place near Andover.—ALAN CHEALES.

THE Rose which was referred to in the last issue of the *Journal of Horticulture* is occasionally met with in the south

of Lincolnshire; at least I presume it is the same that is known as the old Yellow, or, as it is sometimes called, Burghley Yellow. It is a beautiful Rose—I think the brightest yellow of all Roses, and sometimes comes of good form, but frequently fails to open and is at times semi-double. If Mr. Gilbert can tell us how to grow the Rose so that it will bloom freely and well he will deserve a hearty vote of thanks from the whole Rose-loving community. The colour of the petals is as yellow as a Crocus.—SOUTH LINCOLN.

GIVING AIR.

MR. WILLIAM TAYLOR, whose writings on all subjects add, according to my judgment, an extra charm to the pages of the *Journal of Horticulture*, has (page 469) allowed himself to give birth to a suspicion that my practice may not possibly be in harmony with my theory. He may rest assured that I am too old a man and too true a gardener to say one thing and practise another. My years and my experience have taught me that "all wisdom dwelleth with no man," and that it is the grossest presumption for anyone to presume that his way is the only safe one. That is so, particularly with respect to giving air, and admittedly so even by Mr. Taylor himself; so that I think it is rather too much for him to say that I and others who differ from him belong to an old and non-progressive section of gardeners, who have, as he says, "stood still and fostered exploded notions whilst the rest of the world has been moving."

My experience also leads me to dissent absolutely from Mr. Taylor's assumption of the superiority of the young men of the present day over their fathers. I know that "beardless laddies think they are better informed than their auld daddies," but as an "auld daddy" I protest against such a conclusion; and when we are told on almost every hand of the drinking and pipe-smoking habits of young men, of much dressiness, general fastness, and superficiality of attainments, I for one must beg leave to differ from even such an authority as Mr. Taylor. Let us differ from one another with all courtesy, please, for "many men many minds." Let us be just also, for there are many young men of exemplary habits—industrious and persevering; but these are not they who despise "auld daddies" like—X.

ROSES IN POTS.—No. 1.

THE Rose is our national flower, and its national show has come and gone. However much this was appreciated, and notwithstanding all that may be said on the merits or demerits of individual blooms, I would not have Roses as plants grown in pots entirely neglected.

The present season has afforded ample proof of how admirably they can be grown in pots, how amenable they are to training into neat and compact bushes, and how effective they are. Roses in pots have been shown in large numbers this season and in splendid condition. The beautiful groups arranged by Messrs. Veitch & Sons at the London shows in March, and again at Kingston and Richmond in June, and at Bickley in July; the meetings of those champion growers, Messrs. Paul and Son and Mr. Turner, at several places during April and May, clearly show how the Rose season may be extended. Roses in pots are also grown by amateurs, but it cannot be said they have yet attained perfection; but if encouragement is offered I am sure more amateurs will take up the culture of them. I am pleased to find that Mr. Mayo at Oxford has a large collection of Roses in pots, and that they are grown by several amateurs around Reading. At Manchester also I find by your report of the late Show that three growers entered the prize list. Plymouth I find has also made a recruit or two, and were the various societies to offer substantial prizes more growers would enter the field and good plants would be shown by amateurs.

I submit that it is quite within the province of the National Rose Society to offer prizes for Roses in pots; the result would be that not only would good exhibition blooms be arranged on moss, but exhibition blooms would be shown on handsome plants—plants which would make their exhibition more varied and attractive. I do not say that large plants would be forthcoming, but I do not think it impossible. If the plants were pruned, sheltered, and protected in order to keep them back for a certain day, small plants such as nurserymen have would be shown extensively, and which are certainly very attractive to all visitors.

I have grown the following Roses in pots, and will state how they have succeeded with me:—

Anna Alexieff is a very free-blooming Rose in a pot. It is somewhat thin, but indispensable for early work. The blooms are benefited by tying them while opening. It is a very pleasing pink and a good laster, notwithstanding it goes "abroad."

Beauty of Waltham blooms very freely and comes very regular. Too much cannot be said in its praise. It is a quick grower.

Paul Verdier has proved itself one of my best. The colour is pleasing, the shape of bloom good, and the foliage grand. It is very free and a very quick grower.

Victor Verdier.—A very constant and good Rose; always sure to bloom. The blooms being large and of a very pleasing colour it ought to be in every collection.

Marquise de Castellane is the finest forcing Rose out; good substance and very attractive.

Duke of Edinburgh.—Very good for pots. It is a free bloomer, and the colour is most brilliant. Dapuy-Jamain is also very good. Camille Bernardin is very pretty, of good shape and habit, but with me an irregular bloomer.

La France, when well done, is one of the loveliest of Roses grown in pots—the colour so delicate, and the blooms of large size, but every break is not a bloom; foliage magnificent, and good grower.

Paul Néron has only its size to recommend it.

Baroness Rothschild is of the loveliest pink; comes as a rule somewhat thin, a poor laster, very strong grower, and all the blooms do not open at one time; it requires two or three weeks longer growing than several others.

Souvenir d'un Ami I have seen done well. With me it has been an entire failure. The fault may be mine.

Alba Rosea is a sweet and charming Rose, though my plant has not reached the size of some others.

Madame Willermoz is a grand Tea Rose that grows well, blooms abundantly, and has large very showy blooms.

The thirteen sorts named were the plants I first had selected for me. I have since added numerous others, several of which have superior qualities to some described. Madame Lacharme, Capitaine Christy, Madame de St. Joseph, President, Etienne Levet, Edouard Morren, Madame Victor Verdier, Mdlle. Thérèse Levet, Marguerite de St. Amand, Cheshunt Hybrid, Chas. Lawson, Céline Forestier, Marie Van Houtte (a gem of the first water), Centifolia Rosea, Madame Marie Rady, Annie Laxton, and Princess Mary of Cambridge. The above are thirty varieties of very good Roses to grow and bloom in pots, and there are others perhaps equally good.—J. W. MOORMAN.

P.S.—I trust the National Society will receive sufficient support to enable the Committee to hold two Rose shows during a year, and that Roses in pots will be included in its schedule. The Rev. Canon Hole amusingly tells us of the butchers and others around Nottingham growing Roses in pots. If those hard-working men did it then among themselves, surely those who have better and more modern appliances would take the matter up. The Rose season would be extended, cultivation would be stimulated, and the exhibitions would be even more varied and attractive than they are now.—J. W. M.

MANURE FOR AMATEURS—WRAPPING FOR CUT BLOOMS.

I NOTICED in a recent number of the *Journal* that one of your correspondents was in difficulty with regard to obtaining manure. May I ask if any of your readers have tried ivory dust? It is a very valuable manure for Grape Vines and for mixing with the compost for potting plants. Dirty dust—that is, the sweepings of the ivory-cutter's workshop, can be had for about 6s. a cwt., and though I have termed it dirty it is only contaminated by dust from boots and the other accidents of a workshop. Clean dust at about 20s. a cwt. is perhaps the most profitable, because being clean one can extract the gelatine and then have a useful manure. This gelatine, which is obtained simply by stewing the dust, is in reality superior to that obtained from calves' feet, and is especially grateful and serviceable to invalids and young children, the small percentage of phosphate of lime extracted being of great benefit to the latter.

I see that you also speak of wrapping the stems of cut blooms in damp wadding and tinfoil. The latter is rather too expensive when thin sheet gutta percha, such as artificial

flower makers use, would answer as well and be more convenient.—*PRO BONO PUBLICO.*

THE ROSE ELECTION.

As the election this year is to be of a decidedly exhibition character, and as I have also endeavoured to make some qualification for voters, I should like carrying out the thoughts of "WYLD SAVAGE"—to qualify somewhat those on whom we are to vote. "WYLD SAVAGE" has drawn attention to the great similarity between certain Roses. For some years *Lælia* votes have been given to Louise Peyronny.

Now we are only to name forty-eight Roses, and in a stand of forty-eight we should not desire to have two specimens so much alike as to appear the same Rose. I wish, therefore, to avoid this, and unless good cause can be shown to the contrary I propose to give all *Lælia* votes as heretofore to Louise Peyronny; all votes for Ferdinand de Lesseps, Exposition de Brie, or Maurice Bernardin to Ferdinand de Lesseps; all votes for Eugénie Verdier or Mdlle. Marie Finger to Eugénie Verdier; and votes for Baron de Bonstetten to Monsieur Boncenne.

Without some arrangement of this kind the election may in some degree make the position of some of the candidates erroneous. I need not further add that in these similars both Roses must not be named in the forty-eight.—*JOSEPH HINTON, Warminster.*

P.S.—My intention is to bracket these named Roses together in the list, so that it really only amounts to this, that each elector should name only one of each, or any of these four sets in the forty-eight, supposing that they or any one of them is in his forty-eight list.—*J. H.*

NOTES AND GLEANINGS.

THE thirty-fourth anniversary dinner of the GARDENERS' ROYAL BENEVOLENT INSTITUTION was held on the evening of the 4th inst. The chair was occupied by Sir Trevor Laurence, Bart., M.P., who ably advocated the claims of the Institution, and alluded to the great advance that had been made in gardening pursuits during recent years, which was particularly exemplified in the condition of the London parks. Mr. Robert Wrench the Treasurer, Mr. Philbrick, Q.C., Serjeant Cox, and Lord Alfred Churchill also addressed the company in appropriate speeches. Among the company we noticed W. E. Brymer, Esq., M.P.; Major Sandys; Drs. Hogg and Masters; Mr. Shirley Hibberd; Messrs. Veitch, Williams, Fraser, Beale, C. & J. Lee, Deal, and other friends and supporters of this excellent Society.

THE southern show of the NATIONAL CARNATION AND PICOTEE SOCIETY to be held at the Westminster Aquarium on the 18th and 19th inst. is being anticipated with much interest by admirers of those beautiful flowers. The large number of liberal prizes offered will, we hope, induce much competition, for few flowers are more worthy of extended cultivation than Carnations and Picotees. The prizes are open to all exhibitors, whether they are subscribers to the Society or not. A schedule so liberal deserves a liberal response. Notice of entry should be given to the Hon. Sec., Mr. E. S. Dodwell, 11, Larkhall Terrace, Clapham Rise, S.W., not later than the 13th inst. Good prizes are offered for Roses by the Royal Aquarium Company, which will be competed for on the same occasion. Entries in the Rose classes must be sent to Mr. E. Bennett at the Aquarium not later than the 14th inst.

OWING to the short time intervening between the completion of the judging at the NATIONAL ROSE SHOW and our going to press we accidentally omitted from our report the class for twelve Roses in threes; in which class Mr. Baker, Heavitree, Exeter, was placed first; Mr. Ridout, Woodhatch, Reigate, second; Mr. Scott, Warrington, third; and Mr. Jovitt, Hereford, fourth, with varieties very similar to those which were staged in the other prize stands. In the nursery-men's class for twenty-four Hybrid Perpetuals the winners of the second, third, and fourth prizes were Messrs. G. Cooling, Bath; R. J. Veitch, Exeter; and J. Laing & Co., Forest Hill. Mr. Curtis was awarded the first prize, as stated in our report.

MR. GILBERT, Burghley, writes to us as follows on the FRUIT PROSPECTS OF THE YEAR:—"I have just been taking a general view of the garden. The fruit is a wreck I fear, although there was a great show of blossom. Strawberries and Raspberries will not come up to promise. King of the Pippins

is the only Apple with anything like a crop, and strange but true, Glou Morceau Pear is the only Pear. What I shall do for Apples and Pears is a mystery."

MR. W. H. MANSER having tried at our request the EFFECTS OF PARAFFIN on Kidney Beans for destroying millipedes, writes to us that he applied pure paraffin to a portion of the crop: it killed the Beans. He then mixed half a pint of paraffin with three gallons of water and applied it to another portion of the Kidney Beans, and not one of them has been touched since by a millipede, and the Beans are growing very strongly. We are glad to record this experience of Mr. Manser.

AMONG the many hundred Roses in the garden of Shiplate Vicarage, near Henley-on-Thames, are several beautiful blooms of the shy-flowering double yellow Rose—*ROSA SULPHUREA*.

A COMPLIMENTARY DINNER was given to Mr. WILSON (who for so many years has been a valuable assistant at the Crystal Palace Shows) on the 3rd inst. at the Criterion, Piccadilly. The chair was occupied by Mr. Shirley Hibberd, who spoke well, and justly of the guest of the evening. Dr. Denny ably acknowledged the toast of the Royal Horticultural Society, which was proposed by the Chairman; and Mr. Harrison Weir, in responding for the fine arts, dwelt on the good influences of wood engravings on the minds of the masses, and stated that five millions of copies of engravings from his drawings were circulated annually.

THE COLORADO BEETLE.—At the Glasgow Police Board on the 9th inst. it was agreed, on the suggestion of the Lord Provost, that a vigilant look-out should be maintained lest the Colorado beetle should visit our shores. The Privy Council instructions were ordered to be sent to the Glasgow Agricultural Society, with the request to warn farmers on the subject. The Lord Provost said he had seen thousands of beetles heaped upon the American shores as they had been washed in after attempting to cross the Atlantic. While returning home from New York he had seen them on board on the second day at sea. The Dublin correspondent of the *Daily News* also telegraphs that this dreaded beetle "made its appearance on the Dublin quay on Tuesday the 10th inst., close to the Liverpool docks. The specimen discovered was a large one, and was found crawling on a rope."

WE learn that Mr. B. S. WILLIAMS has taken the lead in foreign exhibitors at the Oporto Show, taking the prize of honour offered by the municipality of Oporto, value £50; also four other first prizes. We congratulate Mr. Williams on his success at such an important Exhibition.

WE noticed at the Bickley Show the other day a seedling ZONAL GERANIUM of unusual size which had been raised by Mr. HORWOOD, gardener to J. Lovibond, Esq. The truss almost approached in size the head of a Hydrangea, the colour being orange-scarlet and the flowers of fairly good shape. It is a monstrosity in Geraniums, and will possibly be useful for decorative purposes.

THE bedding-out in the LONDON PARKS is not yet completed. The weather has latterly been too cold for exposing the exotic plants and Ferns, which play an important part in the summer decorations. Many carpet beds are very beautiful. Golden Feather appears to be as popular as ever, and Alternantheras are indispensable. The only plant which is at all likely to rival those in popularity is the Green Gibraltar Pennyroyal, *Mentha Pulegium gibraltarica*. This plant has spread with great rapidity, and must be regarded as the premier "green carpet" plant.

THE quantity of STRAWBERRIES sold in the market of New York city during one day in June was 750,000 quarts, 30,000 of which came by steamer from Charlestown, S.C.; 300,000 from Norfolk, one-quarter of which came from one grower who has over 200 acres in Strawberries; 300,000 quarts came from Delaware and Maryland, a large quantity from New Jersey and points on the Hudson near New York.

THE TEMPERATURE towards the end of last week fell considerably, and the nights were quite cold in the neighbourhood of London. In several districts hail fell, or rather showers of ice. At Kensington on the 5th inst. hailstones were scraped up by handfals, and "snowballing" was indulged in as a novel sport in July. At Swanley in Kent the hail did considerable damage on the 6th inst. in Mr. Cannell's nursery. Dahlias were cut into tatters, and Geraniums and other flowers we noticed in a miserable state. Where the lights were left

open in the Geranium house the ice shower cut quite through the foliage of the plants in the house, and of course destroyed the flowers. No glass was broken. Mr. Cannell is steadily improving this new nursery, and acre after acre is being devoted to the cultivation of flowers. The Geranium house will shortly be a beautiful sight. The collection of these plants is both extensive and choice. A few of the more striking varieties will be noticed in a future issue.

— To PRESERVE FENCE POSTS.—The American *Chemist* says that a western farmer discovered many years ago that wood could be made to last longer than iron in the ground. Time and weather, he says, seem to have no effect on it. The posts can be prepared for less than two cents a piece. This is the recipe: Take boiled linseed oil and stir it in pulverised charcoal to the consistency of paint. Put a coat of this over the timber, and he adds there is not a man who will live to see it rot.

— "T. M." in the "Gardener" says *SYMPHYTUM OFFICINALE VARIEGATUM*, a variegated variety of the well-known Comfrey, is strikingly beautiful. Its large lanceolate leaves are broadly and distinctly margined with creamy white. It is a very effective plant for planting in mixed borders, and is no less so in lines in ribbon borders; indeed, it is one of our very best plants for this purpose, far surpassing the variegated Coltsfoot that was recommended so strongly some years since.

— A TRANSATLANTIC OBSERVER remarks that the value of bones imported annually into England to be used in fertilising the land are computed to be worth ten million dollars. They are obtained from Russia, Germany, South America, and the United States. Throughout Great Britain bones are collected from every possible source of supply. So valuable are bones considered in Germany that a proverb there reads, "One ton of bone dust saves the importation of ten tons of German corn."

— MR. STEPHEN P. SHARPLES, State Assayer of Massachusetts, writing to the American *Cultivator* on the subject of the danger of using PARIS GREEN for destroying the Potato beetle, says that the question of poison is a question of quantities. One pound of poison on a thousand tons of soil is not an alarming quantity when we reflect that the antidote, the hydrated peroxide of iron, is present also. After quoting from Prof. Riley, State Entomologist of Missouri, that Paris green is sure death to the Potato beetle, Mr. Sharples asserts that if he had a field of Potatoes he should neither plough them under nor let them be destroyed, but would protect them with Paris green. Mr. Henry S. Field says, "To get rid of the pests easily take Paris green and plaster of gypsum and mix together in the proportion of 1 lb. of the former to 50 of the latter, and apply the mixture by shaking it over the Vines when the dew is on them." As evidence is forthcoming that the dreaded beetle is now in Europe the American mode of extirpating it is worthy of being recognised.

WEST KENT HORTICULTURAL SOCIETY.

BICKLEY, JULY 7TH.

By the kind permission of G. Wythes, Esq., the Exhibition of the Society was held in Bickley Park, and a site more suitable for such an event it would be difficult to find. The Park is contiguous to the railway station, and is ornamental by the many fine trees it contains, notably Elms and Cedars, and has also a sufficient expanse of open pasturage. The Exhibition was held in three marquees: one, about 150 yards in length, contained the collections of plants; another, somewhat smaller, fruit, vegetables, and cut Roses; and a third table decorations. The day was fine with the exception of a passing shower, and a considerable number of visitors, the gentry and inhabitants of the neighbourhood, attended the Show during the afternoon.

Although the Exhibition was of considerable magnitude, a glance was only needed to show how much the Society was indebted to the chief nurserymen for furnishing the tents so attractively. When such firms as Messrs. Veitch, Williams, Wills, Rollisson, Carter & Co., and Laing unite their forces under canvas there is always sufficient for the public to see. All those firms were well represented at Bickley; many gardens in the neighbourhood also staged creditable collections, in a few cases excellent; and Messrs. Cant, G. Paul & Sons, and others provided a feast of Roses.

Messrs. James Veitch & Sons occupied the stage at one end of the chief tent, and Mr. B. S. Williams the other. Prominent in the Chelsea collection were the bright and massive *Croton Macafeeanus* and the equally bright and not less distinct *C. McArthurii*. *Caladium Madame Alfred Bleu* attracted by its clear sharp colours, and the golden-foliaged *Princess of Teck*

was in excellent colour. *Nepenthes* were also included, and a choice collection of insectivorous plants, consisting of *Dionæas*, *Darlingtonias*, *Sarracenias*, and *Droseras*. The new white *Hydrangea Thomas Hogg* proved its lasting qualities, and colour was imparted to the group by some of the best of the tuberous *Begonias*. Very bright and also very remarkable was the new scarlet *Clove Tom Thumb*, the flowers being large and perfect, yet borne on stems only a few inches in height. Orchids were represented by *Oncidium papilio Kramerii*; *Cattleya Mendelii*, very fine; *Lælia purpurata*; *Masdevallias*, including the bright yellow *M. Davisii*, and several *Cypripediums*, amongst which were such new and beautiful varieties as *C. selligerum* and *C. superciliosum*. *C. Veitchii* was also in splendid condition. Amongst the Ferns *Pteris serrulata maxima cristata* was very noticeable by its stateliness and general elegance. Messrs. Veitch further arranged a semicircular group of Japanese *Acers*, surrounded with small well-grown *Roses* in pots, and margined with *Eurya latifolia variegata*—very effective; also *Spiræa palmata* and an extensive collection of cut *Roses*.

The Holloway collection was also choice, varied, and attractive. Amongst the Orchids *Lælia majalis* was very charming, and not less so was *Cypripedium superbiens*; *Odontoglossum citrosimum* was also in excellent condition. In this group *Ixora fibrobanda nana* was conspicuous, the plant being very dwarf, with handsome heads of flowers. *Dennstaedtia davallioides* Youngii, the fine Australian Fern, was exhibited in a small state, and in that state it is very elegant. *Maranta Massangeana*, *Bertolonias*, *Panax laciniatus*, *Dipladenia Brearleyana*, *Dionæa muscipula*, *Nepenthes*, *Croton Victoria*, and other choice plants were included in this excellent group.

Mr. Wills's plants occupied a large space of staging, and occupied it well. Pitcher Plants were in capital condition, as of course were such *Dracænas* as *Willisii*, *Elizabethæ*, *Leopoldi*, and *Voluta*; *Golden Caladiums* Queen, Prince of Wales, and Princess Royal; *Croton Earl of Derby*; *Phyllotanthium Lindeni*, *Maranta Massangeana*, *Cephalotus follicularis*, *Platycoerium grande*, *Yucca filamentosa variegata*, and very choice *Palms* were noticeable in this good group. Messrs. Rollisson's collection was similar in character, and included some Orchids, notably *Odontoglossum vexillarium* and the distinct *Cattleya granulata*. The group of Messrs. J. Laing & Co. was brightened by some well-grown plants of the best varieties of *Bicolor Geraniums*. *Richard Thornton* is extremely fine; as also is the very dark *Czar*, *C. H. Pollard*, and *Mrs. H. Weir*. Double *Petunias* were also included, one of them, *La Fleur de Janear*, being of wonderful size and finely mottled; also cut *Roses*, *Louis Van Houtte* being extremely fine. Messrs. Carter's was also a large group of general decorative plants—too extensive, indeed, to particularise.

The above collections are first mentioned because of their pre-eminent merit, and we now briefly notice a few of the competing collections. The first class in the schedule was open to all, yet only one exhibitor staged twelve plants in flower—Mr. Mumford, gardener to J. Scott, Esq., and who was worthily awarded the first prize. The classes for fine-foliaged plants call for no comment, nor do the show and fancy *Pelargoniums*, although good prizes were offered; the season, however, is fully too late for *Pelargoniums*. *Zonal Geraniums* were very good; Mr. Neighbour, gardener to G. Wythes, Esq., Mr. Coppin, and Mr. Talmage securing the prizes. Mr. Neighbour's plants were 4 feet in diameter and not more than a foot high, and were good in foliage and flowers. The others were rather too formal—too closely tied. *Tricolor Geraniums* were excellent, the best we have seen this year. The plants were 3 to 4 feet in diameter and in good health and colour, the successful exhibitors being Messrs. Coppin, Lover, and Neighbour. Double *Geraniums* were also very good, especially those staged by Mr. Cole, gardener to A. Mitchell, Esq.

In division 2, for members of the Society, six very good stove and greenhouse plants were exhibited by Mr. Crane, gardener to Mrs. Green, who secured the first prize, also a similar award for six fine-foliaged plants, which were really excellent. *Croton angustifolium* was in superb colour, and *Dæmonorops fissus* and *Areca lutescens* were very good. *Roses* in pots were poor, *Fuchsias* very good, Mr. Neighbour again winning, followed by Mr. Cole and Mr. Pepper. *Gloxinias* were very good, Messrs. Jeffreys and Osborne being placed equal first. Mr. Neighbour won first honours for *Begonias* in flower, and Mr. Talmage, gardener to A. B. Pearce, Esq., first for "foliage" *Begonias*. The exhibition of these was rather extensive. There was a good show of *Achimenes*. Mr. Neighbour was an easy winner, followed by Mr. Monckton, gardener to J. B. Alston, Esq.; and Mr. Jeffrey, gardener to T. J. Smith, Esq. Exotic Ferns were good and British Ferns excellent, Mr. Neighbour winning in both classes for six plants, followed by Mr. Clifford, gardener to J. Batten, Esq., and Mr. Gammon. For single specimens Mr. Osborne won with a grand example of *Davallia Mooreana*; Mr. Field, gardener to W. Palmer, Esq., being second with *Lygodium scandens*; and Mr. Neighbour third with *Adiantum pedatum*. Mr. Mumford staged good *Dracænas* and secured

premium honours, and Mr. Monckton was successful with *Caladiums*. He exhibited capital plants.

ROSES.—In the open class for forty-eight varieties, trebles, grand collections were staged by Mr. Cant, Colchester, and Messrs. G. Paul & Son, Cheshunt. Neither of those famed rosarians have staged better, if as good, triplets this year. They were awarded equal first prizes, and well did they deserve them. There was scarcely a failing bloom in either stand. It is not necessary to name the varieties, but it may be said that the two new Roses, E. Y. Teas and Madame Prosper Langier, were in splendid condition. For twenty-four single blooms Messrs. Cant, G. Paul & Son, and J. Laing & Co. were placed in the order named for collections of remarkable quality. Louis Van Houtte in Mr. Laing's stand was the finest bloom of that fine Rose we have ever seen exhibited. For twelve Roses of any variety Mr. Cant won with magnificent examples of Marie Baumann; Messrs. Paul & Son being second with a charming stand of *Mdlle. Marie Finger*, and Capt. Christy third with Mons. Noman. In the amateurs' classes Capt. Christy won the first place for twenty-four varieties, single blooms, with a really excellent collection; Mr. Hall, gardener to J. Whitehead, Esq., was second; and J. A. L. Lovatt, Esq., Chislehurst, third. For twelve varieties W. Palmer, A. B. Pearce, and A. Mitchell, Esqs., were awarded the prizes for very good stands; and for six blooms of any variety Capt. Christy won with admirable examples of Madame Lacharme, Mr. Field being second with *Senateur Vaisse*, and Mr. Neighbour third with *Pierre Notting*.

Other cut flowers and Grasses were exhibited, but there was nothing noteworthy except the cut sprays of *Fuchsias* in twelve varieties. These were very attractive, the prizes being won by Messrs. Neighbour and Cole. But of special merit was a collection of *Verbenas* in the following twenty-four varieties from Mr. Cannell, Swanley Nurseries:—*Annie*, *Lady Ann*, *Lady Cowley*, *Lady Leigh*, *Basilisk*, *Grand Duke*, *Ariosto Improved*, *Pentonia*, *Grand Monarque*, *Antoinette*, *Peacemaker*, *Ensign*, *Beauté Supreme*, *La Loire*, *Jno. Stainer*, *Pomeraine*, *Blue Boy*, *Jas. Birkbeck*, *Princess of Wales*, *Crimson King*, *Purple Emperor*, *Mrs. Owen*, *Isa Brunton*, and *Lady Folkestone*. Mr. Cannell also exhibited *Silver Tricolor Geranium Lady Dorothy Nevill* in excellent colour, quite small plants arranged as a pyramid. The effect was very good.

FRUIT.—The display, which was only of moderate extent, contained some good Grapes, Peaches, and Strawberries. The best black Grapes, and good they were, came from Mr. Crane, followed by Mr. Rolliason and Mr. Pepper, and the best white Grapes (well-finished Buckland Sweetwater) from Mr. Jeffrey and Mr. Horwood. Mr. Crane also exhibited *Royal Muscadine* in very good condition. Melons were small, but Mr. Crane's *Bloxholm Hall*, which received the first prize, was of splendid quality, and nearly as good was *Eastnor Castle* from Mr. Clifford. Mr. Horwood had the first honours for Peaches, Nectarines, and Cherries. Good Peaches were also exhibited by Mr. Neighbour, and Nectarines by Mr. Boosey, who had the second prizes in those classes. For three dishes of Strawberries Mr. Moyce, gardener to W. Dalton, Esq., won with *British Queen*, *President*, and a variety resembling *Oscar*; and for one dish Mr. Neighbour won with *Sir J. Paxton*.

VEGETABLES.—These were very good indeed. In the collections of nine and six varieties first honours were secured by Messrs. Neighbour and Crane respectively. Messrs. Rolliason, Eke, Gammon, and Monckton also exhibited well in these classes. Messrs. Neighbour, Eke, and Cole were successful in the class for salads. Tender and True was the best Cucumber. It was exhibited by Mr. Neighbour. Mr. B. S. Williams exhibited a brace of *Osamston Manor*, and Messrs. J. Laing & Co. a brace of *Stanstead Rival Cucumbers*. Both were very fine. Some very good vegetables were also exhibited in the cottagers' classes.

TABLE DECORATIONS.—A tent was set apart for these. The arrangements were chaste rather than elaborate. Mr. Russell Oliver's £10 prize was won by Miss J. Lovibond with a charmingly arranged table. Miss Boosey, Miss Oliver, and Mrs. Wood also exhibited well.

The Show was well arranged, and the arrangements reflected credit on the Hon. Sec. and the officers; but the Exhibition was not equal to the Show of the Society that was held last year at Chislehurst.

THE NATIONAL ROSE SHOW.

THERE are many jottings I should like to make anent our grand tournament on the 4th, but I must defer them for the present. There is one point, however, on which I should like to speak very decidedly, and that is the great obligation we are all under to Mr. Newman, who so ably carried out the details. When I asked the Committee to secure his services I felt sure from all that I knew of him we had the right man in the right place, but I had no idea that he was so thoroughly effective an organiser as he is. His quiet and unobtrusive manner

is not indicative of listlessness, on the contrary his energy is very great; while all who work with him can testify that there is nobody with whom it is more pleasant to be associated. And when it is remembered that the Hall was not given up to us until six o'clock the evening before, and that not a hitch occurred in the whole of the arrangements, that the exhibitors found everything prepared for them, and that the Judges were enabled to proceed to their work punctually at the time appointed and the public admitted at the hour announced, I do not think I shall be considered as saying too much when I say that the chiefest merit of all this is due to him. I am sure his many friends would be delighted to hear that he had some fitting sphere in which his peculiar abilities might be appreciated.—D., Deal.

ARTIFICIAL ROCKERY.

THE accompanying figure represents Messrs. Dick Radclyffe and Co.'s decorations at the Royal Horticultural Society's Show on June 19th, which were greatly admired by the visitors, and were referred to as follows in our report of the Show:—

Fig. 13.

"The reception in the great tent was appropriately cool, for Messrs. Dick Radclyffe & Co. had erected a charmingly natural pile of artificial rockwork. The stones were carpeted with moss, and from the crevices sprang fresh green Ferns, Begonias, &c. Spouting fountains sent jets of tiny spray from the base-like miniature springs, and from the top of the rock a gurgling stream of water poured into the pool below. The whole had a very refreshing effect." The figure does not quite do justice to the decoration as arranged at the Show.

COOMBE COTTAGE,

THE RESIDENCE OF E. C. BARING, ESQ.

COOMBE, or Coombe Warren estate, which belongs to H.R.H. the Duke of Cambridge, has long been noted for the purity of its springs. In the reign of King Henry VIII., at the time that Cardinal Wolsey built that magnificent Palace Hampton Court, he had the water conveyed from the Coombe springs to the Palace by means of leaden pipes. The distance these pipes traverse is from four to five miles, and they pass under the Thames at Kingston. The main body of water used at Hampton Court Palace is still supplied from Coombe, and the conduit houses are still remaining, apparently as perfect as they were in Wolsey's time.

Mrs. Loudon in one of her admirable works has mentioned the noble Gorse bushes at Coombe, but of those there are few remaining. The estate was looked upon as extremely sterile, and, to quote the words of an old farmer, "not worth 1s. 6d. per acre." But on this once sterile ground many mansions have been erected, and the Gorse bushes have given place to

choice collections of Conifers, Rhododendrons, and other shrubs, which grow remarkably well.

Coombe Cottage, the subject of our present engraving, has grown from a "cottage" to a mansion. The grounds are beautifully laid out, and are furnished with the choicest of flowering and other shrubs, and the gardens contain many glass structures for the cultivation of indoor fruit and flowers, which are much in demand all the year round. We first entered a large span-roofed house containing a miscellaneous collection of stove plants, principally grown for cutting from, or of a small size for table and room decoration. Trained up the rafters are *Stephanotis floribunda*, *Dipladenia amabilis*, *Jasminum Sambac flore-pleno* and *ligustrifolium*, all very sweet-scented, and hence they are favourites of Mrs. Baring. We also noticed large masses of *Cœlogyne cristata*, *Cattleyas Trianae* and *Mossiae*, and a well-bloomed specimen of *Lælia*

purpurata. Parallel to this house are two other span-roof houses. In the first are planted *Gardenias*, which are models of health. A corner in this house is devoted to *Euphorbia jacquiniæflora* also planted out, which is the best way to obtain a supply of large and brilliant flowers. *Eucharis amazonica* is also largely grown, and suspended from the roof are *Clerodendrons* and *Stephanotes*. The other house is divided in two departments, the first being set apart for the large-flowering section of *Pelargoniums*, which are grown extensively for decorative purposes; and in the inner part is a rare and extensive collection of cool Orchids making extraordinary strong growths. Amongst others we noticed quantities of *Odontoglossum Pescatorei*, *Alexandra*, *citrosmum*, and *nævium*, also several plants of *Lælia Dayana*, *Masdevallias*, *Lycastes*, &c. A few Ferns are also grown in this house, such as *Adiantum cuneatum* and *gracillimum* and a variety of *Gleichenias*, all doing

Fig. 14.—COOMBE COTTAGE.

well. A large *Azalea* house was next entered; it is 60 feet long by 20 wide, and contains an extensive collection of plants, all of which have been repotted and are rapidly making new growths. There are also some very fine plants of *Rhododendrons jasminiflorum*, *Alexandrae*, and *Princess Royal*, which Mr. Baker speaks most highly of. In the same block, but in a west position, is a long half-span house used as a show house, the front being plentifully furnished with such flowers as are in season; and on the back walls are some very fine *Camellias*, *Lapagerias*, *Plumbago capensis*, and other greenhouse climbers, while beneath are large *Camellias*, *Rhododendrons*, &c.

We next arrive at a series of lean-to houses. The first compartment is a vinery carrying a beautifully even crop of *Black Hamburgh Grapes*. The bunches are of medium-size, berries large and of an intense black colour. The second is devoted to *Peaches* and *Nectarines*, which will be soon ready for gathering. *Royal George* and *Violette Hâtive* *Peaches* and *Elruge Nectarines* are carrying heavy crops. The back wall of this house is planted with *Camellias*, which are doing remarkably well, the shade from the *Peach* and *Nectarine* trees suits them admirably. The next compartment has one *Nectarine* in it, and a very fine tree it is, covering a space of 20 square feet, and perfectly furnished from top to bottom. The top of this range is devoted to *Roses*, principally *Teas* and *Noisettes*,

which are in great demand. The *Roses* are planted out and do remarkably well.

Passing through the kitchen garden we come to a large span-roof house rich in general stove plants, Orchids, *Nepenthes*, &c. In this house are some plants of *Calanthe Veitchii* of extraordinary strong growth, some especially fine *Ixoras*, *Crotons*, *Palms*, *Anthurium Scherzerianum*, *Alocasias*, *Caladiums*, *Adiantum farleyense* and other Ferns. *Nepenthes Sedeni*, *Hookerae*, and *Rafflesiana* are of remarkable colour and with very fine pitchers. The cool end of this house is devoted to Orchids—*Pleiones*, *Cypripediums*, quantities of *Dendrobium nobile*, *Lælias*, *Cœlogyne cristata*, *Thunias Bensonæ* and *alba*, and a remarkable plant of the very curious *Dendrochilum filiforme* with wonderfully fine racemes of flowers. At the extreme end of the house a dull and unsightly wall has been converted into a pleasant scene by placing peat against the wall and supporting it with a wire framework, on which a great variety of Ferns are now growing in luxuriance. Adjoining this house is a *Black Hamburgh* house. The crop is fast colouring, and affords evidence of good culture. On the south wall of this garden are the *Peach* trees, which are covered with glass, and in the front near the glass numbers of excellent *Tomatoes* are ripe.

In the frame-ground are extensive span-roofed pits, one of which has been devoted to *Vines* in pots. The crop has

been cut, one of the finest crops we may state that it has been our good fortune to see for many a day. The Vines were grown on the double-root system—that is, the canes were pegged over the rims of the pots into a bed of rich soil, into which they rooted and thence derived much support. On the other side of this house is growing quantities of Negro Largo and Brown Turkey Figs. The Negro Largo Mr. Baker considers the best of all Figs; it is dwarf and prolific as well as of excellent flavour. The corresponding pit is now filled with Tomatoes just ripening, this crop having succeeded French Beans. A very useful range of three compartments for the growth of early Grapes, Melons, and Cucumbers has just been erected under Mr. Baker's superintendence, also a similar but somewhat larger range, the two end houses being for Strawberry and French Bean forcing, and the middle one for Muscats, which were planted during October last, and now cover the roof. Numerous smaller ranges of pits and frames are also provided. The glass structures are numerous and face every point of the compass.

We pass on to what is known as the Dairy Lawn, at the extreme end of which is the model dairy fitted-up with every modern appliance. This lawn has been much extended by Mr. Baker, and is a very pleasant part of the grounds. Leading from this lawn to the pleasure grounds are a series of panel beds, divided by Yew hedges and bounded by a high wall massively covered with creepers, principally sweet-scented, and the beds are filled with sweet-scented flowers, such as Roses, Mignonette, sweet-scented Geraniums, and the Sweet-scented Verbena (*Aloysia citriodora*). A continuation of this border leading to the house is tastefully planted with Abutilons, Cannas, Sweet Peas, and subtropical plants, with a front row of Viola (blue), and *Dactylis variegata* (white), mixed. From this point and on the front lawn a view embracing nearly thirty-five miles of country is to be seen. Leith Hill, Box Hill, and the Crystal Palace are all visible. An ornamental terrace wall fronts the house, where there are numerous tastefully arranged baskets and vases. Two flights of steps bring us below the terrace wall into the rosery, flower garden, and another lawn, on which are some famous and extensive banks of Rhododendrons, including all the best new varieties. These form a grand feature to the place. At the bottom of this lawn are flower beds and some famous standard Rhododendrons, one approaching from 15 to 20 feet high and as many in diameter. There are also amongst the Conifers a fine *Pinus lasiocarpa*. P. Pinsapo and a large specimen of *Thuja Lobbii*, a perfect cone, are noteworthy. Roses are grown in large numbers on arches, pillars, in beds, on their own roots, and on dwarf and tall standards: all are doing well, but Mr. Baker is in favour of dwarfs. Abutting these grounds are several acres of wood with tastefully laid-out gravel and grass walks, some winding to the substantial and well-built model farm.

The kitchen garden is plentifully stocked with every requisite; it is also ornamental from the plan that has been adopted of training the leading shoots of the pyramid fruit trees on arches over the walks. The effect of this arrangement is very pleasing, and does not impair the fruitfulness of the trees.

There are many places of more imposing exterior than Coombe Cottage, but few are in better order; and there are not many gardens where better practice is carried out than that of Mr. Baker, the able, and courteous as well as able, gardener.

A MORNING AT CHESHUNT.

"AFTER thunder, rain," remarked Socrates on a too memorable occasion. After the turmoil of the Rose battle on the 4th how refreshing a morning among the new Roses at Cheshunt!

Starting from Liverpool Street—a great improvement on the old Shoreditch terminus—a pleasant run of forty minutes lands at the Cheshunt station. The Old Nurseries are about twenty minutes' walk, down a lane first, where every cottage has its miniature and well-appointed Rose garden, and then along the high road which once led to the great bed of Ware. Stronger attractions now stay the traveller. On entering the nurseries the attention is at once caught by the collection of Roses in pots. How the beautiful little plants can be such a blaze of beauty and yet do their duty again in the autumn is a marvel, yet so it is; I was informed they would then again be equally fine. But my mission was to the new Roses and seedlings. On our way to these we passed by the original Cheshunt

Hybrid, a dismal-looking affair now the old parent stock, but the parent of flourishing children settled all over the world already. "It grows very well with me in Auckland," was casually remarked the other day to Mr. Paul by a stranger. They are most anxious looking for seed pods on this Rose, but at present have had no success; the hips attain a certain point and then drop off. It seems doubtful whether these hybrids are not hopelessly sterile.

Arrived on the ground, the seed beds of last year were first of all inspected. Funny little things the young Roses are. One sturdy little fellow of 3 inches high had his five buds already, and had been allowed to keep them in compliment to his audacity; ordinarily such precocity is promptly suppressed.

Passing on we inspected some splendid François Michelon as large as Paul Neron, but shaped infinitely better; Julie Touvais with most exquisite—almost Homère petals in half-open bud; Emily Laxton like Monsieur Noman in the bud, but opening far better than that most queer-tempered fair-weather Rose; John Bright, bright indeed, spreading quite a fiery glow over a long row of standards; Sultan of Zanzibar, flashing its dark crimson; and Duke of Connaught, with which I was extremely pleased. It has the peculiar dark red brilliancy of Monsieur Boncenne with an infinitely better shape, and with buds after the manner of Camille de Rohan at his best; foliage very firm and substantial. Altogether a very great acquisition.

And now as to the newest of all. Many "mute inglorious Miltons" are worked on Briars and then suppressed, not appearing afterwards quite good enough for commerce. Others are still *sub judice*. I was much struck with one violet-coloured, which I am not allowed to speak of. I named him on the spot "The Dark Horse" in consequence. Another seedling of the most brilliant scarlet has the Noisette foliage of Boule de Neige; if it can be had solid enough Boule de Feu will begin a new and very charming strain for us. Marguerite Brasseur seems a more robust Charles Lefebvre, but almost too similar for two in a box. Duchesse de Vallombrosa was magnificent; she will speedily take her place amongst the cream of our white Roses. Capitaine Christy very fine. I hope Mr. Camm will recant in this instance, as well as in that of Madame Lacharme. And, to return to the seedlings, the Duke of Teck I may speak of. Mr. Paul thinks him the best Rose since the Duke of Edinburgh, than which there is, I think, no other such light red Rose in existence; its pure distinct scarlet is almost dazzling, the foliage robust, the shape and substance in all ways satisfactory. Amongst other novelties I heard also of a pink sport from Maréchal Niel. It has been obtained from a tree in a nobleman's garden; should the two buds that have been inserted prosper it will one day be famous.

To conclude, in his inviting little red paper of trains and directions to summer-coming visitors Mr. Paul gives a list of various kinds of Strawberries. It was no part of my business to inspect the plants in the nurseries, but I can answer for the excellence of the fruit in combination with cream after luncheon.—A. C.

THE ROSE YEAR.

ROSES here (Longleat) and elsewhere about the neighbourhood where they do not receive primary attention are poor, being wanting in size and substance. They were much injured by late frosts; and the dry parching weather which followed, aided by aphides, made them grow less vigorous than usual. There are some growers, however, who seem to defy the weather, and amongst the former is Mr. Keynes. This veteran showed some splendid flowers at Frome; one François Michelon was a marvel both in size and shape. Other good flowers were Capitaine Christy, Duchesse de Vallombrosa, Etienne Dupuy, La France, Madame Lacharme, Mlle. Eugénie Verdier, Mlle. Thérèse Levat, Souvenir de Madame Boll, Comtesse Nadailac, Madame C. Kuster, Monsieur Furtado, Niphetos, Alba Rosea, Marie Van Houtte, and Souvenir d'Elise Varden. Roses about here were about at their best at the time of the National Show.—WILLIAM TAYLOR, Warminster.

THE very early blooms of Gloire de Dijon and Devoniensis opened very badly, but the later flowers are expanding freely. They are very profuse and very globular. I have had a "Gloire" in every box of twenty-four I have set up this season. I could cut hundreds of blooms from the trained pyramids which were not pruned. Some of the Maréchal Niel blooms were good. Souvenir de Malmaison has been very good. It appears to be

a very good season for globular Roses, but, singular to say, while it suits these it has suited Général Jacqueminot, which was shown by Mr. Paul and Mr. Turner at Richmond in extraordinary condition. Mons. E. Y. Teas is doing well this year; it is a grand addition to dark Roses, and it has a worthy light associate in Duchesse de Vallombrosa. These two new Roses will be in great request. Le Rhone, Abel Carrière, Baron de Bonstetten, Madame Prosper Langier, Star of Waltham, Sir Garnet Wolseley, Prince Arthur, Marchioness of Exeter, Emily Laxton, Miss Hassard, Royal Standard, and John Bright have all been in fine condition, and have attained a foremost place as exhibition Roses. Triomphe de France is not a "triumph" in England, and while the Rev. J. B. M. Camm should be in every garden it has not won a high position in the stands.—J. W. MOOREMAN.

ARTIFICIAL FERTILISERS.

"A RETIRED GARDENER" details a very interesting practice with so-called artificial manures in the garden, but it is of rather an expensive, not to say wasteful a character. He admits as much when he says that an equally good effect will be produced if only half the manurial elements are used, the rest of the dressing being of simple water. Yet even with this reduction his quantities so far surpass any usual or necessary amount, that it will be useful to consider what they really come to. On a few rows of Peas extravagance in manuring is of no particular consequence, but when we come to some acres of kitchen or flower garden it would inevitably be a deterrent from what on a reasonable scale would be a valuable aid to the gardener.

First as to water. "A RETIRED GARDENER" prescribes an unlimited quantity, which he says he is confident would exceed a gallon to the square foot of ground, to be applied once a-week. But this quantity is equal to a rainfall of 2 inches per week, or as much as two days of constant rain in the seven. It therefore exceeds 8 inches per month, which is an amount that does not occur once in a dozen years. Half the quantity, or 4 inches in a month, is above the average of even a very moist summer. Those, therefore, who have not an unlimited supply of water or of labour at their command may well be content if they can in a period of drought administer once a-week only half a gallon per square foot, using, of course, all proper precaution against evaporation.

Next as to fertilisers. "A RETIRED GARDENER" suggests 1 lb. of guano to ten gallons of water, which he would use on 10 square feet of ground, though he admits it would suffice for 20 square feet if the ground were previously soaked with plain water, and a solution of this strength he would apply once a-week; but 1 lb. of guano to even 20 square feet is equal to about a ton per acre, and to 10 square feet it is equal to 2 tons per acre. If this is to be applied once a-week, say during only eight weeks of drought, it will come in the one case to 8 tons, in the other to 16 tons per acre, and the cost of this will be, at importers' prices, £120 to £240. With nitrate of soda and superphosphate of lime "A RETIRED GARDENER" is only a little less extravagant. He would add to each ten gallons of water 1½ lb. of the latter and a quarter of a pound of the former, to be distributed as before, once a-week, on 10 to 20 square feet of ground. This would in eight weeks come to 10 to 20 tons per acre of superphosphate, costing £60 to £120, and 2 to 4 tons of nitrate of soda costing £30 to £60, the total cost being thus £90 to £180 per acre for a single crop!

It need not be said that such quantities and such outlay are alike unknown in either agriculture or horticulture on a large scale, and that no plants exist which could assimilate, far less repay, anything approaching to such doses of manure. In ordinary farming 1 cwt. of nitrate of soda or 3 cwt. of guano are a usual dressing once in the year in addition to farmyard manure. The effect of such an application is instantly visible, and few farmers find profit in more. Mr. Lawes' valuable experiments on farm crops on the same ground during twenty years in succession, show that when no farmyard manure is given the highest fertility may be maintained by annual dressings containing only 3 cwt. of nitrate of soda; that 4 cwt. gives somewhat larger returns, but not in proportion to the increase in the manure; that 8 cwt. gives a little more than 4 cwt., but that hardly any addition is obtained to the crop by manuring beyond that point. It is, indeed, true that the gardener desires his crops to be of greater succulence and luxuriance than the farmer does, and we may therefore concede that

he may beneficially employ double what the farmer finds profitable; but he should also recollect that it has been proved that when plants intended for food are too richly fed their juices contain the manuring ingredients in an undecomposed state, and that sheep and cattle have often been poisoned by eating herbage or Turnips raised by overdoses of nitrate of soda, or ammonia, or guano.

If, then, we take as the limit of safe application to each crop double the amount that a farmer would use we shall find that when we reduce it to pounds, to be applied to 10 square feet of ground, we ought not to exceed—of guano one-third of a pound, or, instead of guano, of nitrate of soda a quarter of a pound, and of superphosphate half a pound. These may be sprinkled on the surface in rainy weather and left to be washed in. In dry weather they may be dissolved at once in five gallons of water and poured on, or, what will be better, they may be divided into four doses and repeated at a fortnight's interval. If too much water is given so as to flow away in the subsoil or the drains it will wash away the manure, and this is no doubt the way in which the excessive doses of manure administered by "A RETIRED GARDENER" were disposed of, and thus were prevented from poisoning the plants and their consumers.—J. B. K.

THE NATIONAL ROSE SHOW.

FROM first to last your Rose number is a pleasure to me, and I doubt not very many more of your subscribers, for throughout the number but one spirit seems to pervade it, and that is of the congratulatory or jubilant order. Why even, *mirabile dictu!* "A PARSON'S GARDENER" can say a kind word about a "WYLD SAVAGE," and also write an exceedingly pleasant letter upon some of the best and oldest of our Roses. Surely the Rose millennium is not a thing of the future, but has come and gone last week.

And this reminds me of the wish expressed by my respected, not opponent (let even a "WYLD SAVAGE" claim fraternity) but *confreire*, as to a wish that I should make some criticism and remarks on the National Rose Show. This I have already done in the Rose number, but the exigencies of going to press were so great that my remarks and yours were mixed up together, so that there is still left plenty to say about our great Show; and indeed strange it would be if so great an event as the first exhibition of the rejuvenated National Rose Society could not furnish food for many articles in the English Rose Journal. Now that the dust has a little subsided from the hot racecourse, now that the Rose boxes are empty and all the great shows are over, now that the stupendous whole is removed from the mind's eye, let me say a few words about some minor things that struck me.

And first of all I wish once more to congratulate you, the Editors and Proprietors of the Rose Journal, in having the best contested fight for the cup which you presented for competition. This, as most of your readers will remember, was for twelve blooms, distinct varieties. The stands which were staged in this class were both numerous and good, but I do not hesitate to say that in my humble opinion the stand which won the first prize was not only the best in the Show but also the best twelve I ever saw. Mr. Smallbones, of Chatteris near Cambridge, must be a wonderful grower to be able to stage such blooms as they were. All my notes of the Show were left at your office, but if I remember rightly there were blooms of La France, Eugénie Verdier, Charles Lefebvre, Marie Baumann, &c., which were all splendid specimens. I never saw a more even lot. There were twelve blooms of equal size, of bright fresh colour, perfect form, and well set up. The only drawback (alas! that there should have been one for such blooms) was that they were too crowded together. The box was never intended for twelve such blooms as those; it might have accommodated six, but not more. No sign of moss was to be seen and very little foliage. The blooms were so large that they touched one another. Mr. Keynes, who judged them and who travelled back with me, quite agreed with me as to their great excellence; so that the Editors may rest assured their cup was well contested for and well won.

Working one's way up the room I do not think anything was more striking than the boxes of nurserymen's Tea Roses. One thing that I remarked was the one marvellous bloom (at least) that each nurseryman had—e.g., Mr. Davison of Hereford showed a marvellous bloom of Comtesse de Nadailac, Mr. Keynes an equally good bloom of Niphetos, and Mr. Cant of Boule d'Or. Now these three Roses are so difficult to make anything of that it is quite an event to see good blooms shown, and if the National was memorable for nothing else it would by me be ever remembered for the astonishing blooms of Tea Roses, which are so difficult of cultivation.

In the class for twenty-four distinct varieties (Hybrid Perpetuals) Mr. Curtis staged a very beautiful lot of blooms. I could not help exclaiming, "Bravo dear old Devon!" as we

marked his name down as the winner of the first prize. The blooms were so very fresh, clean, and even that it would be difficult to imagine a finer lot if they had been cut that morning within a few miles of London. I am delighted to see how well Mr. Curtis has staged this year, and, contrasting his stands with those of the few last years I am amazed at the marvellous improvement. If he goes on in this way he may soon play the part that Mr. Jowitt has played among the amateurs.

Beginning with small things, that gentleman has within (I believe) three years advanced to the highest position and won the premier prize of the year, and this brings me to a consideration of his stand and some of the lessons it teaches me. They may be nothing worth, but such as they are I offer them to the attention and friendly criticism of your readers. I think it will be granted that Mr. Baker's (who won the second prize) blooms were fresher than Mr. Jowitt's, but the latter's were larger and perhaps a little more even throughout. Certainly Mr. Baker's Roses were more highly coloured than his great rival's, but some of his blooms were undoubtedly smaller than any of Mr. Jowitt's. Taking this for granted, let us look at the various Roses shown by these twin giants. Mr. Baker showed forty-eight of the best-known varieties, such as Alfred Colomb, François Michelin, Marie Baumann, Duke of Edinburgh, Ferdinand de Lesseps, Maurice Bernardin, &c., and nothing could have been more beautiful than his stands; but it is evident that some of his best blooms were of varieties which are never large, such as his favourite Duke of Wellington. Now Mr. Jowitt's stands, while containing all the best varieties, also had splendid blooms of older sorts, discarded by many and grown by very few. In his stands were found Madame Charles Crapelet, Lord Herbert, Madame Boutin, Madame Bellon, L'Esmeralda, Jules Margottin, &c. From this I wish to draw the inference that to show forty-eight well we amateurs must largely increase the number of our varieties. Mr. Jowitt, I believe, grows, and grows largely, about 150 sorts; now I am not sure, but I should certainly be "surprised to hear," that Hercules has more than seventy sorts of Hybrid Perpetuals. The advantage, then, that Mr. Jowitt has this year is great, because he has so many more varieties, all of which are capable of bearing grand blooms if forced on and well cultivated, although perhaps as a rule they give you but indifferent flowers.

Now may I without presumption or self-praise speak of my own case as bearing-out this point? I grow less sorts even than Mr. Baker. I certainly have not more than sixty sorts, and when you take out of these Duc de Rohan, Emilie Hansburg, and other late sorts, I have not more than fifty. To show, therefore, forty-eight sorts is always a matter of great difficulty to me, and I never could do it were it not for my Teas. So before the Alexandra Palace Show, after my return from Torquay, as I was settling on the boxes, the thought occurred to me, Don't try and show forty-eight or even thirty-six; throw all your strength into twenty-four trebles, and try and make a respectable stand. I did so and was first, beating both Mr. Baker and Mr. Jowitt. As my small number of varieties are all the very best sorts, and cultivated in twenties, I was able to cut three young blooms of twenty-four sorts with ease, and so was fortunate enough for once to win a first prize. But here I wish to make a remark which will startle if not astound not a few, and that is the fact that I cut in the sun. Yes, at the hottest period of the day. Our last train to London goes at 5 P.M., and my boxes and man were not home from Torquay till 2.30 P.M., so I with fear and trembling did a thing I never ventured on before—I cut my blooms very young in a broiling sun and won a first prize. No one (my man told me), would believe this at the Alexandra, and I should very much like to hear the opinions and custom of some of your readers. I am told that Mr. Curtis recommends cutting in the sun, and as he is a diligent reader of the Journal perhaps he will state his reasons for this, if it is the case. But my own experience, furnished by Mr. Jowitt's stands, makes me feel convinced that we who try to show forty-eight distinct, ought to grow far more sorts than we do, and if we feel disinclined to do this, then let us be content to leave the larger classes for the giants, and confine ourselves to trebles and twenty-four and twelve varieties.

Some reader may here triumphantly exclaim, "But at Hereford this year, on Mr. Jowitt's own ground, Mr. Baker turned the tables on him and won the cup from the lion's teeth." Yes, so he did, and much do I, one of his oldest friends, congratulate him on this great achievement. But my reasoning on this point is not so totally demolished as you may think, for the cup prize at Hereford is for thirty-six varieties, not forty-eight, and the alteration in number makes all the difference, for it is the last twelve that tries us, and which often compels us to put in small blooms. A greater triumph than that won at Hereford by Mr. Baker is not to be imagined, and all, not perhaps excluding even Mr. Jowitt, will rejoice with him on taking Mr. Cranston's cup to Exeter. What a year of great contests will 1878 be when the two giants meet to contend for the ownership of the cup! for I cannot doubt that it lies between these two alone.

Before I conclude this discursive letter let me say a word of

praise as to the arrangements made by the Secretaries and Mr. Newman for the accommodation of the exhibitors in St. James's Hall. I am told that there was a concert the night before, and yet at 6 A.M. all the staging was up, the classes marked out, and every exhibitor's name placed on the exact spot his boxes occupied. There was not the slightest confusion, no alterations made; all went easily and smoothly, and without confusion the Hall was cleared and the judging completed in about an hour and a half. A grand Show it was, and one ever to be remembered—a Show which will, whatever be the fate of future exhibitions, redound to the credit of the Committee and the Honorary Secretaries, and furnish food for discussion and congratulation among rosarians for many months.—WYLD SAVAGE.

NOVELTIES IN THE ROYAL GARDENS, KEW.

THE rockwork presents a pretty show of flowers, inclusive of many species of individual interest. *Delphinium cashmerianum* is one of the best for this position, being dwarf and bearing large blue showy flowers. It was introduced to Kew about three years since, and few only have been distributed. *Anemone obtusiloba*, though known long ago, is now extremely rare, and was perhaps lost to cultivation until a few years since, when seeds were received which produced the present specimen. It has large leaves and is very compact, scarcely at all spreading; the flowers are pure white, and produced several together on short pedicels above a leafy involucre. It is a native of the Himalayas, and was first introduced by the Royal Horticultural Society. The Edelweiss, a plant of interest to tourists in particular, is here in flower. It is said not to grow below a certain elevation, and is brought down by travellers to show that they reached this particular altitude. It is known as *Gnaphalium Leontopodium* or *Leontopodium alpinum*, and though considered difficult of cultivation is not really so. In winter it appears dead, and is then often thrown away by mistake. *Phlox ovata* is one of the best of a genus containing many handsome species. Its flowers are much like those of *P. reptans*, which is used for spring bedding; but the leaves are broad, and the stems stiff and erect. *Primula sikkimensis* is much rarer than need be, and here has been in good condition. *Wulfenia Amherstiana* is a choice and rare alpine. The flowers are blue, prettily disposed on one side of erect stems, and are associated with leaves of somewhat Primrose-like appearance.

Fremontia californica, on the ornamental wall near the Orchid house, is now in splendid condition. A great part of the tree is almost hidden with large golden saucer-shaped blooms, equal in size to those of a Gum Cistus. The tree is clothed with very neat foliage, and forms a first-rate wall-covering. Though perhaps hardy as a shrub, it only reaches perfection in a similar position. Near this the newly-introduced *Lilium cordifolium* is flowering, it is said for the first time in Europe. It is the species to which by some botanists *L. giganteum* is referred as a variety. It is much more difficult to manage. As a garden plant it is likely to be much inferior to *L. giganteum*; the flowers are fewer, and do not compensate by larger size.

Galax aphylla, a somewhat rare herbaceous plant, is striking in that department. It is densely tufted, the leaves round and dark green, among which arise the numerous spikes of pure white flowers. *Gillenia trifoliata* is not often seen, though forming a pretty combination of white flowers, red stems, and green trifoliate leaves. The roots are medicinal, having in some degree the properties of *Ipecacuanha*.

Flowering in house No. 1 we find *Napoleona imperialis*, a plant of great structural interest to the botanist, and of interest to the general observer from its peculiar conformation and resemblance in miniature to *Rafflesia*, the peculiar Vine-parasite of Sumatra exhibited in the adjoining museum. *Rafflesia Arnoldi* is destitute of stem and leaves, the flower, of which it consists, reaching $3\frac{1}{2}$ feet across. Another interesting plant here in flower is *Spathicarpa platyspatha*, a dwarf herbaceous Aroid, the spadix of which is adnate to the flat spathe, so that the flowers appear as if borne along the midrib of a leaf.

In the Palm house we are delighted with a combination of foliage produced by climbers growing together. One of these is *Passiflora quadrangularis variegata*, the variegation of which is extremely good and constant; golden blotches are distributed over the leaf. The other is *Dioscorea vittata*, the leaves of which are reddish purple relieved with grey down the centre. These colours produce a very pleasing effect. It would be easy to suggest other associations of similar character. Thin-growing plants have often room among their branches for the

twining of a slender climber, and bare stems could often be clothed in this way. We may here suggest the attachment of certain epiphytes to the stems of living Tree Ferns. Shade-loving species of suitable habit are found among the Bromeliaceae. Some Orchids might be found to thrive, and a few trailing Gesneriaceae are quite at home in this position.

The newly-imported *Vanda cærulescens* var. *Boxalli* is now flowering in the Orchid house. It is not considered equal to the species, but is extremely pretty, all being pure white with the exception of its blue lip. The showy Orchids of most attraction now in flower are *Phalænopsis Lüdemanniana*, *Aérides odoratum* and *multiflorum*, the nearly white-flowered *Oncidium pulchellum*, *O. leucochilum*, with spikes of great strength; *Barkeria Skinneri*, *Oncidium Krameri* and *Papilio*, and *Cypripedium Hookeri* and *superbissimum*.

The new *Begonia Frobeli* in the cool end of the T range is commencing to flower freely. It seems to have found less favour than it deserves, but here is quite ornamental, and takes a good position among the tuberous species. It is difficult to imagine why these have not been grown for exhibition, considering the gorgeous display they are capable of producing with but little trouble.

In the next house are many beautiful examples of Gesneriaceae, inclusive of the genera *Achimenes*, *Gloxinia*, *Biglandularia*, *Gesnera*, *Sheeria*, *Tydaea*, and others, few only of which are novel; but it is difficult not to mention their value as a class for the greenhouse in summer, a time when houses are often empty or nearly so. These are an important feature in the establishment of L. Van Houtte at Ghent, but in this country at least meet with far too little appreciation. A representative set would be highly attractive at the summer and autumn flower shows.

Roella ciliata is extremely pretty in the conservatory, and to which we draw attention from its great beauty and rarity. It is a small evergreen shrub with slender stems, producing large bell-shaped blue flowers. It was introduced from the Cape more than one hundred years ago.

AMONG THE ROSES AT WOODLANDS.

To obtain a clear idea of the relative value of our best Roses it is necessary to see them growing side by side, not planted singly but in considerable numbers of each sort, so that one may not be misled by individual peculiarities, of which there is an undoubted risk when a single plant only of each variety is before one, as is usually the case in private gardens. It is true that such exhibitions of Roses as the National afford us a sight of picked blooms of our best sorts in such a guise as we unfortunately but too often see them only in a prize stand; yet I much fear that these noble examples of skilful culture convey no very just or fair conception to the mind of the ordinary practitioner of their appearance when not enjoying the special advantages of high culture and most careful tending, or, what is more to the point, of their value or otherwise for the embellishment of a garden. Not that I wish to say one word in disparagement of Rose shows, for our national flower is worthy of all honour, and, moreover, such shows are most useful in a variety of ways, such as in bringing new and worthy varieties prominently before the public, testing the merits of new sorts with old, affording Rose-growers an opportunity for an interchange of ideas, promoting social intercourse in its most innocent genial form, and above all in tending to popularise Roses and Rose culture.

Acting upon the idea set forth in my first sentence I went last week to inspect the Roses of Messrs. William Wood & Son in their Woodlands Nursery at Maresfield near Uckfield; and under the courteous guidance of the head of the firm, Mr. Charles Wood, and his youngest son, I went through the whole of their Roses, comprising I suppose all the varieties really worth growing, every one of which was to be seen by the hundred, perhaps I should be safe to say by the thousand, for in the open air they extend over many acres, and under glass they fill house after house and range after range, affording one such a sight of standards, half-standards, and dwarfs, of Roses in pots, as I will very frankly own I have never seen before, and in my experience of nurseries and gardens has been somewhat extensive. It will therefore be understood that I had a rare opportunity of seeing Roses new and old, good and indifferent, under what may be fairly claimed as the best possible conditions for forming a reliable opinion of their worth.

Maréchal Niel and Gloire de Dijon are undoubtedly our two most popular Roses, as was clearly shown by the immense

numbers of both which were flourishing in rude health and in every form from dwarfs to standards. Messrs. Wood consider that The Garland, a hybrid climber sent out by them many years ago, makes quite the best stock for Maréchal Niel, tending materially to promote that free strong growth for which "The Marshal" is so remarkable when bud and stock agree. This is an important matter, as although I have a splendid tree of it some 20 feet high on the common Briar, others have not done so well, and some have failed outright.

Of other sorts grown in very large quantities—a sure indication of popularity—La France still holds a prominent place as one of the very best pink sorts, as do the rich crimson Duke of Edinburgh and the lovely white Boule de Neige, always good, but occasionally giving us a flower that is the very perfection of form and purity of colour. I was glad to find that John Hopper, too, continues to hold a high position. I suppose we have nothing more beautiful among Roses, or any flowers, than an opening bud of John Hopper with the recurved petals just showing that rosy crimson, or rather pink, tinge which is so charming. Moss Roses are, of course, grown extensively, the old White Bath being more vigorous than I have before seen it. A still more vigorous white Moss is Reine Blanche, very hardy, beautiful in bud, and expanding into large flowers. This is an excellent sort, which everyone ought to grow by the dozen, for we never can obtain enough of it for mixing with other cut flowers.

Reverting now to my notes of the best sorts, a new one named Abel Carrière first claims notice. It has large flowers, very full petalled, of perfect form; is glowing crimson in colour, and is in every respect worthy of Messrs. Wood's description as a "superb new Rose." In Madame Prosper Langier we have another new one with magnificent flowers, very large and full, and of a lovely soft shade of carmine. Madame la Baronne de Medeni is also new in colour. It is pink shaded with violet; it is very full and of perfect form. Another variety of 1876 is named Rosa alba—Pompon blanc parfait, and answers perfectly to the catalogue description:—"Flowers small and of exquisite form, colour pale flesh passing to pure white, a charming miniature Rose," to which I may add that it forms a pretty little bush such as one admires in a border or bed. Dingé Conard as I saw it appeared quite worthy of being termed "one of the finest new Roses of the season;" its petals are of great size, and the colour a brilliant crimson. Olga Marix has charming white flowers, cupped and with elegant petals. It is a valuable sort. Catherine Bonnard of the Hybrid China section has brilliant crimson flowers and is very striking. It is a new variety, and is considered very suitable for pillars. Sultan of Zanzibar is a good new Rose, remarkable for its colour—a deep crimson, or, as the catalogues say, blackish maroon. Panachée Langroise is a very distinct variety with deep flesh-coloured mottled flowers, which tell well among other varieties. Of older Roses Marguerite de St. Amand was as usual most lovely with its abundant bold bright pink flowers. Abel Grand was also very fine; like John Hopper, its expanding flowers are so charming that we should value it for them alone when in that stage, even if they were not so perfect when fully developed. François Michelin was very good; it has lovely deep pink flowers, very large and full. Paul Neron was of course conspicuous, its strong healthy growth and immense flowers never failing to attract attention. Large quantities of it are grown, but it must be termed somewhat coarse and vulgar when fully expanded. Felix Genaro was grown in quantity, and its flowers were certainly very fine. It has now been under cultivation for a good many years, and there has been frequent discussion as to its merits. I have grown it and have not liked it, but after seeing it so perfect as it was at Woodlands I can understand why some should term it a good Rose and some a bad one, for it is evidently much influenced by soil and situation. Bessie Johnson was very good, with large full flowers of a charming delicate pink shade and very sweet. Marquise de Castellane was in splendid condition, but then I have never seen it otherwise; it is undoubtedly one of our best Roses. Abbé Bramerel has deep rich crimson flowers, and is a very striking variety.

Tea Roses, though grown in such large numbers being mostly in pots, were past their best, but I was able to see and admire the crimson-flowered Duchess of Edinburgh, a distinct and valuable acquisition to this class, as is also Cheshunt Hybrid, of which there was a goodly number of standards in the open nursery. Both are vigorous growers, and both are indispensable. They will prove of especial value for clothing buildings of light-coloured stone or stucco, as well as for

mixing with the more numerous shades of white and yellow Roses.

As a curiosity among Roses I may mention an introduction from Japan called *Rosa rubiginosa Regeliana*. It has clusters of large single crimson flowers, has a dense clothing of curious deep green foliage; the stem is thickly set with thorns, altogether forming a plant of singular appearance.

I have thus noted a few, and only a few, of the many sorts of Roses grown at Woodlands. I would fain dwell upon some others, but as that may not be now I may appropriately conclude by congratulating, not Messrs. Wood alone, but Rose-growers generally upon the excellent condition of the whole of the Woodlands Roses; for Woodlands is the source from whence many nurserymen draw their supplies.—EDWARD LUCK-HURST.

WIMBLEDON HORTICULTURAL SOCIETY'S ANNUAL SHOW.

PARK HOUSE, Wimbledon Park, the residence of Mrs. Evans, was the place selected by the Committee of this Society to hold their fifth annual Exhibition, an exhibition worthy of the place and neighbourhood. The schedule consisted of 120 classes in three divisions—gardeners, amateurs, and cottagers. The cottagers came out in great force, but the amateurs were much less numerous. We hope that another season they will take courage and do honour to the Society which takes the trouble to offer prizes for their produce. Division 1 brought out some very good productions.

Class 1 was open to all comers for six stove and greenhouse plants in flower. Mr. Smith, gardener to J. C. Joad, Esq., was placed first with a very fresh collection; Mr. Moorman, gardener to the Misses Christy, second; and Mr. Jordan, gardener to J. Boustead, Esq., third. Mr. Smith's were the smallest plants, but exceedingly fresh and well flowered, and included a very fine *Oncidium sphacelatum* and *Cattleya Mossiae*. The second-prize collection contained amongst others very fine and well-bloomed plants of *Clerodendron Balfourii* and *Stephanotis floribunda*. In the class for six stove and greenhouse plants in or out of flower Mr. Smith was again first, Mr. Jordan second, and Mr. Moorman third. The first-prize collection contained a very fine and beautiful-coloured plant of *Croton Johannis*, and the second a very fine plant of *Cocos Weddelliana*. For four stove and greenhouse plants in or out of flower Mr. Bridger, gardener to F. B. Thomas, Esq., was awarded the first prize; Mr. Bentley, gardener to Sir Thomas Gabriel, the second; and Mr. Stratton, gardener to Miss Forbes, the third. Six miscellaneous plants in 9-inch pots brought a strong competition, and Mr. Jordan, Mr. Smith, and Mr. S. Chapman, gardener to R. Macabe, Esq., divided the honours in the order named. Mr. Jordan's plants were *Dracenas amabilis* and *Youngi*, *Pandanus Veitchii* and *Vandermerschii*, *Demonorops fissus*, and *Aphelexis macrantha purpurea*, all excellent and well-grown plants for such small-sized pots. In the class for six and four exotic Ferns there was also very keen competition, Mr. Jordan being placed first in the class for six plants for good examples of *Davallia Mooreana*, *Neottopteris nidus*, *Gymnogramma chrysophylla*, and *Adiantum farleyense*, *concinnum latum* and *cuneatum*. Mr. Smith was placed second and Mr. Bentley third for good collections; and in the class for four plants Mr. S. Chapman, Mr. Lyne, and Mr. Curtis, gardener to — Barlow, Esq., were first, second, and third respectively.

Fuchsias were exhibited extensively, and seldom have we seen finer plants, most of them being large and well bloomed. Messrs. Lyne, Jordan, Moorman, Roser, and Stratton were awarded the chief honours. Scarlet or Zonal Geraniums were good. Mr. Roser was in his usual place with fine examples of *Matilda*, *Charles Burrows*, *Caxton*, *Mrs. Tait*, *The Shah*, and *Harry King*. Mr. Lyne was placed second; the other winners were Mr. W. Mayer, Mr. Bentley, and Mr. Chapman, who all showed very creditably. *Achimenes* came from Mr. Bentley and Mr. Lyne, who were awarded the first and second prizes respectively for six plants; and in the class for three plants Mr. S. Chapman was awarded the first prize.

Caladiums were extremely fine, more especially those exhibited by Mr. Jordan, to whom the first prize was unhesitatingly awarded for grand examples of *Belleymei*, *Triomphe de l'Exposition*, *Meyerbeer*, *Excellent*, *Prince Albert Edward*, and *Adolphe de Nassau*. Mr. Stratton also exhibited a very good six, and received the second prize. In the class for three Mr. Bridger, Mr. Cole, and Mr. Lyne were awarded the honours in the order named.

Passing some minor classes we arrive at the Roses. In the class for twenty-four blooms Mr. Moorman was a good first; Mr. Fanning second; and Mr. Elliott, gardener to the Rev. J. M. Brackenbury, third. It would be well for the Society to alter the wording of the schedule another year by substituting the word "trusses" for blooms; for the want of a definite term a good collection which would have been placed second was disqualified.

Other prize-winners had a narrow escape; but while the Judges were quick, and properly so, to discern the terms of the schedule in one respect, they did not recognise the important condition that the varieties were to be distinct. In the second-prize stand we noticed two Roses named *Duke of Wellington* when the stand did not contain one of that variety, and two *Paul Verdier*, while the name of *Centifolia Rosea* was attached to a scarlet Rose. In the gardeners' classes for twelve blooms Mr. Kent was placed first, Mr. Tucker second, and Mr. Smith third; and for twelve blooms (amateurs) Mr. W. Scott, New Wimbledon, a most ardent lover and good grower of Roses, was first. This collection was decidedly the best in the Show. Other exhibitors of Roses were Mr. Mayer, Mr. Brown, and Mr. Marsh-Stiles.

Fruit was not very extensively shown, but was very good, especially the Strawberries. The first prize for a single dish was awarded to Mr. Jordan, who exhibited *Her Majesty*, a very large and good-flavoured Strawberry. The other prizetakers were Mr. Chapman and Mr. Cole. Mr. Kent was first for a collection of fruit, and shared the honours with Mr. Burden for both Peaches and Nectarines, and Mr. Lee and Mr. Fanning for Grapes.

Vegetables were well to the front. Mr. Lyne, Mr. Jordan, and Mr. Kent were first, second, and third respectively in the class for twelve sorts; and Mr. Moorman, Mr. Chapman, and Mr. Bridger in the same order for six sorts. The cottagers' productions were both extensive and very good.

Special prizes were offered by Mrs. and Miss Reeves for dinner-table plants. In the class for twelve plants Mr. Jordan was awarded the first prize with graceful examples of *Cocos Weddelliana*, *Areca lutescens*, *Demonorops fissus*, *Aralias Veitchii* and *elegantissima*; *Dracenas terminalis*, *Cooperi*, and *gracilis*; *Pandanus Veitchii*, *Annassa sativa variegata*, and *Croton angustifolium*. Mr. Smith was placed second, and Mr. Lyne third. In the class for six plants Mr. Chapman, Mr. Cole, and Mr. Bridger were placed in the order named. There was great competition in these classes, and the plants exhibited were excellent.

TWO-DAYS ROSE SHOWS.

The neck of these has been pretty well broken; but there is one offender in the metropolis—the Aquarium, and it is to be hoped that all the members of the National Rose Society will remember that they are pledged to do all in their power to discountenance two-days Rose shows. Some intend carrying this out to the letter, and it will hardly be fair for other members to take advantage of their consistency and secure prizes which they might possibly not have obtained had those who held back for this reason competed.—A LOVER OF CONSISTENCY.

NOTES ON VILLA AND SUBURBAN GARDENING.

ADVANTAGE should be taken of every shower to plant out Brussels Sprouts, Savoys, Kale, Broccoli, Coleworts, &c., into their permanent quarters. Those useful vegetables, so necessary for the winter supply, cannot become established too early if both quantity and quality are wished for. The greatest trouble to us, and doubtless to many others, is to have space at command to plant the above-named crops when opportunity offers; therefore clear the ground of all early crops as soon as they are over, such as Peas, Cauliflowers, &c. We gathered our first Peas on the 19th of June, but the crop was not heavy; we therefore cleared them off at once. William I. Peas have podded abundantly and were very fine. They are now over, and our late successions are not looking well. Such sorts as *Champion* of England and *No Plus Ultra* are far beneath their ordinary heights. The ungenial spring, followed by real summer weather, has caused them to flower prematurely. In order to secure a late autumn supply we shall sow a few more rows of early sorts—*Advancer* and *William I*. It will only be a chance crop, and the result will depend materially on the season. The early-sown *Scarlet Runners* and *Dwarf French Beans* are looking well, and there is yet time to make other sowings for late supplies. Asparagus beds must be kept free from weeds, and no more heads must be cut, or the supply of next year will be weakened. Early-sown Turnips have in the majority of cases "bolted," or run to flower before attaining any size. Other sowings should be made. *Veitch's Red Globe* is a very useful sort to sow after this date. Thin-out advancing crops of Turnips, Onions, Carrots, and Beet if not already done. Celery where required should be planted out for an early and main supply. The *Incomparable White* is one of the best for early use, and *Major Clarke's Red* is a good sort to follow. Potatoes are looking well and promise to be good this season. They can be dug as wanted, and the ground planted again with winter vegetables. If a sowing of Parsley is made now on a south or warm border and not picked during the autumn it will, if not crowded, give an abundant supply throughout the winter. A sowing of the *Rosette Colewort* ought also to be made, the plants from which will be useful for filling spare ground as it becomes cleared.

In the flower garden the work will consist principally in removing dead flowers, pegging down and stopping all such plants that are required to cover the ground rapidly, and occasionally mowing and clipping the edges. Roses, Clematises, Wistarias, and other plants covering walls have grown very rapidly, and require thinning and nailing in their places. Clematis lanuginosa and lanuginosa alba are blooming very freely in many places, and C. Jackmanni is promising a fine display of flowers. The small sweet-scented white Clematis flammula is very pretty, and is a fast grower; it ought to be in every collection. Primulas and Cinerarias will now require pricking out of their seed pans, afterwards keeping them close and shaded for a few days. A frame facing the north is a very good position for them, and when well established they will be benefited by the lights being drawn off during mild nights. More seed may yet be sown of Cinerarias, Calceolarias, and Primulas. The seedlings will in all probability make useful little plants for spring decoration.

Chrysanthemums not already in their blooming pots must be repotted at once, for if neglected at this season and the roots become matted together and the tops stunted it will be impossible to have healthy specimens. A rich yet porous compost suits them. We generally pot ours in 9-inch pots if large blooms only are required; but for specimen plants we use 12-inch pots. Pegging, stopping, and tying must be duly attended to, to secure plants of good shape. If the tops of the shoots are made into cuttings and inserted at once and grown-on without allowing them to flag they will make useful little plants, which are often valuable for particular decorative purposes. Four to six cuttings in a 6-inch pot and there allowing them to remain to bloom is the best way of providing showy little plants.

Hedges of all kinds, such as Privet, Yew, Laurels, Holly, &c., will require clipping in order to retain their shape and make a close compact growth; but in cutting Yew and Laurel we prefer a common pruning knife. The Yew hedges are then greener, and Laurels have their leaves left perfect, which in all probability, if the shears were used, would be cut in half. Holly makes one of the finest of hedges, but to induce rapid growth they should not be clipped in their young state, except merely taking off a gross leader here and there to keep the top somewhat level. After they have been established six or seven years they may be cut into shape to form a complete hedge.—J. W. MOORMAN.

DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

HARDY FRUIT GARDEN.

ALL the growths not required on the wall trees have been cut-back, and those that are wanted either to furnish the walls or supply fruiting wood have been secured to the walls. As far as practicable all fruit trees which have ripe fruit have been protected with nets. As usual the birds find out the weak places and carry away the best fruit, notwithstanding all precautions.

We have commenced layering the Strawberry runners, beginning with Black Prince and Keens' Seedling. Before this is printed the largest proportion of them will have been layered. Some growers have tried the system pursued at Loxford Hall of destroying the beds after once fruiting and replanting annually, and having failed they doubt whether the statements made in this Journal are correct. What object, we wonder, could be gained by stating what was not the fact in a case of this kind? The only object most gardeners can have in writing to periodicals specially devoted to their work is to diffuse useful practical information; and our experience, gained by a dozen years of practice, is that the only sure way of securing a crop of Strawberries on this soil is to plant every year. Our plants are now being layered in 60-sized pots—that is, pots about 3 inches in diameter inside measure. No drainage is placed in the pots, except a little moss or turfy peat over the apertures. Over this a pinch of soot is sprinkled to prevent the ingress of worms. The pots are then filled up with a compost of loam and decayed manure in the proportion of three to one. We always select runners from the plants that bear fruit. All barren plants are rejected. This is important, as many plants are to be found without fruit, and the progeny almost invariably is barren the following year. Such plants, moreover, always throw out the strongest runners. In our collection of more than a dozen varieties there is not a barren plant to be found. In two or three weeks at most after layering the plants should be cut away from the parent, and never at any time should they suffer by want of water, or in any way receive a check. The ground should be prepared for them as soon as a space can be cleared from other crops. This year we shall plant after Cauliflowers and Peas. It would be better if we could plant on ground that had been allowed to be fallow from a crop the previous autumn, but this we cannot do. Directly the other crops are cleared off the ground is trenched for the Strawberry plants. We generally have all the plants out by the last week in July, and as they are turned carefully out of the pots they do not feel the effects of removal. Red

spider is a desperate enemy to the young plants, and unless due precautions are taken the plants suffer severely. Another cause of failure may be from the plants remaining in the small pots until they are pot-bound. On one occasion we could not plant out until near the end of August owing to the ground being occupied by another crop. That season all the plants were potted in rich soil in 5-inch pots, and by the time the ground was ready the plants were large and in vigorous health. With many want of time may be urged for all this work. We must find time or our crops would be worthless. Runners for plants for fruiting in pots are prepared in the same way.

PINE HOUSES.

The suckers are ready for taking off and potting from those plants that are now fruiting. We have not a house ready, and will have to delay the work until we have. Pines in most establishments are now being crowded in a corner, or their cultivation being discontinued altogether. As a commercial speculation it will be difficult to make them pay for their cultivation, although there will always be a demand for a limited quantity of good English-grown fruit, especially of Queens. Many gentlemen and the nobility generally will prefer to see the fruit growing in their own gardens, even if it is not any more profitable to grow Pines than it is to cultivate dessert Oranges. Our own stock now comprises Queens principally with a very few Smooth-leaved Cayennes and Charlotte Rothschild. We manage with a very limited number of fruiting plants to cultivate them so that a succession may be obtained all the year round. In cold weather we have kept Smooth-leaved Cayenne a month in good condition. In less than two weeks the suckers will be potted and plunged in a brisk bottom heat. No heat is applied from the hot-water pipes at present, nor will it be necessary for a month longer. If there is any mealy bug in the establishment a careful look-out must be kept to prevent its getting on the Pines.

Fig and Orange Trees in Pots.—The Fig tree when grown in pots requires very different treatment from what is usually given to it when planted in a border under no restriction. It is not likely to grow too strongly confined to the limits of a 12-inch pot, and in such a pot a good-sized tree can be grown, and under good management it will produce a fair crop of fruit. Our Fig trees are potted in good turfy loam and decayed manure, and the potting ought to be performed annually. The trees also must be surface-dressed when they are making roots freely. This—with abundant supplies of water and thoroughly syringing the trees, especially the under sides of the leaves, to prevent red spider from attacking them—will secure good results.

Orange trees are very subject to be attacked by scale, and this pest clings to the branches and the leaves like limpets cling to the tide-washed rocks; it cannot be dislodged by the most furious syringing, nor is it easily poisoned by the use of washes however strong. Hard washing with a sponge and soapy water is the best way to eradicate it. It takes time to do this, but we have not found any other mode effectual.

GREENHOUSE AND CONSERVATORY.

In every department at present there is plenty of work to do. Even here, what with tying-out the growths of the plants and rearranging the stages as plants go rapidly out of bloom, much time is taken up. The secret of success here as in every other department is to have everything done at the right time. If a plant remains pot-bound week after week until the ball of roots is as hard as a cricket ball, it is not possible to pot it as it ought to be done, and the roots cannot be disentangled without causing great injury to the plants. Stopping the young growths just at the right time is a work of some importance: this work if neglected cannot by any after good management be remedied. The plants must also be freely exposed to light, and the air must play freely amongst the branches, although it is also an evil to allow the plants to be exposed to cutting winds.

Softwooded plants, such as Cinerarias, Calceolarias, Primulas, &c., do best in this neighbourhood if the pots are placed in a house facing north and sheltered by a wall a few feet higher than the glass at the highest part. The plants are potted-on as they require it, and especially must they be kept quite free from insect pests. An invasion of green fly very soon destroys the soft brittle leaves of either Calceolarias or Cinerarias; the latter are also much subject to the attacks of thrips. We generally flower the plants in 8-inch pots, and the potting material used is good turfy loam four parts, one part leaf soil, and one of decayed manure. If the plants are doing well they will soon cover the upper part of the pots with large succulent leaves. It is injurious to expose the plants to heavy rains, and it does harm to syringe them overhead.

FLORIST FLOWERS.

We would lift the Tulip roots if we could spare the time; probably they will be done by the end of this week. Next week will be a busy one with southern florists, as it is their national exhibition of one of the most prized of all florist flowers by the general public—viz., the Carnation and Picotee. The flowers at Loxford, if the weather should be warm, will be in about the right time. The Slough collection is not quite so early, but

then it is not necessary that the fourth part of Mr. Turner's flowers should be in to place him in a favourable position. At Larkhall Rise, Clapham, is to be seen the largest and choicest amateur's collection in the south, owned by E. S. Dodwell, Esq. No doubt this will also be about right, although its owner was some time ago rather anxious about having the flowers in at the time of the exhibition. Earwigs are a serious enemy to us, and we have to watch for them every night with the aid of a lamp. They eat the petals at the base, and one will spoil a bloom in a single night. The flowers should be exposed to the light until they are nearly expanded, afterwards it is necessary to shade them to prevent their being injured by sun or rain. Roses have flowered very freely with us this season, and the blooms have been of excellent quality. Pippings of Pinks have been inserted under glass in a shady position. The growth was rather too strong; we would much rather have taken it when it was younger and more succulent. Pansies are flowering most profusely and well. Hollyhocks and Dahlias must be attended to by having the growths trained to the sticks as they advance.—J. DOUGLAS.

TO CORRESPONDENTS.

* * All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

HUMEA.—G. Walsh, Rockbeare Court, Exeter, wants some small plants of *Humeas*.

HYBRIDISING (G. B.).—We know of no good work on the subject. There is an excellent essay among Mr. Knight's horticultural papers.

PLUMS DEFORMED (Irish Subscriber).—They are destroyed by a parasitic fungus, the spores of which are wintered in the bark and soil probably. Scrub the stem and branches with brine. Pare off the soil in a circle extending beyond the circuit of the branches and burn it.

GRAPES SPOTTED (H. B.).—Your Grapes are attacked by the disease called "spot." It arises from a defective supply of sap. The roots require a supply of liquid manure, and more water probably; ventilate also sufficiently yet carefully.

LATE STRAWBERRY (H. C. P.).—Try the Elton.

COLEUS NOT COLOURED (R. H. P.).—We can only advise you to allow the roots of the plants to become pot-bound, yet affording plenty of water and growing the plants in the full sun. Coleuses are sportive, and some plants do not colour well. The best plan is to select the cuttings from the best coloured shoots.

SEEDLING COLEUS (E. R., York).—We think it sufficiently distinct to be worth growing.

PROPAGATING EUCHARIS (A. M. A.).—This is a very free-growing bulbous-rooted stove plant, and it increases at a very rapid rate. It is propagated by dividing the bulbs when they have increased too much for the size of the pot in which they are growing. Pot in turfy loam, a little leaf soil, and decayed manure, with sand added if the loam is of a clayey nature. The plants require considerable supplies of water when they are growing freely, and after blooming less water is required for about two months, when they may be started to grow again, and they will flower as freely as they did before their season of rest. The temperature best adapted to their wants is a minimum of 55° in winter and 65° during the summer months.

CHEAP ORCHIDS (Rev. A. K. C.).—Many of the finest species of Orchids are imported in large quantities at uncertain intervals, and after large importations they can be purchased at a cheap rate, and those who wish to purchase should put themselves into the hands of some of the large firms who import, asking them to advise them of any fresh importation. By watching the advertising columns of this Journal it will be seen that large importations are frequently sold at Stevens's rooms, Covent Garden. The trade growers do not send out the plants until they are established, but even then the choicest species may often be obtained at from 3s. 6d. to 7s. 6d. per plant. At Stevens's rooms they are sold in bundles as imported, and occasionally at very cheap rates. It is quite another thing if a gentleman wishes to form a collection of Orchids and orders them from the nursery, irrespective of the stock in hand; he may require to pay a couple of guineas for a plant that might have been purchased the previous season for three half-crowns. The reason is very simple—the stock has been nearly sold out, and there are no fresh importations expected just at that time.

SEEDLING FUCHSIA (A. B.).—The flowers are fine, and so peculiar that we think it deserves cultivation. The other specimen we think is only a variety of the common Ribbon Grass, but cannot be certain without seeing a spike of its flowers.

TRANSPLANTING LARGE YUCCA AND ESCALLONIA (C. B.).—If you are careful to have a ball of earth undisturbed about the roots you may remove the plants safely.

PARTITIONING GREENHOUSE (A Constant Reader).—It will answer to partition off part of your house, which including the pipes will be a warm house, having lights to open, so as to allow the warm air to pass into the cold division in case of necessity in severe weather. It will be "necessary to partition off under the stage as well as above it," but this part may be of wood or other opaque material, whilst above the stage should be glass.

IMPREGNATING CUCUMBERS (Idem).—It is quite unnecessary unless you require seed—the fruit swells just as well without impregnation as with it. If seed be not wanted the fruit is impaired for use by the formation of seed.

VINE UNFRUITFUL (Idem).—We should say your Vine is unfruitful from the wood of last year being imperfectly ripened, but in the absence of data we are unable to say with certainty. Keep the laterals well stopped and the principal shoots rather thin, fully exposing the foliage to light and air.

THINNING BRANCHES OF FOREST TREES (J. B.).—All those you mention may have their branches moderately thinned now, but if large or numerous

branches have to be removed, mark them now and cut them off at the end of October.

PELARGONIUM SEEDLINGS (C. Bilson).—All the petals had fallen. We cannot select from the legion of new varieties. Go to a flower show and select those you admire. They can be bought of the florists.

ROCKERY (Mrs. W. H.).—Any of the chief florists in London could supply the plants.

DOUBLE GERANIUMS AND FUCHSIAS (T. M., Huddersfield).—Six good double Geraniums are—Wonderful, scarlet; Madame Thibaut, magenta rose; Madame Emilio Ballet, white; Louis Boutard, salmon; Augusta Villamora, orange scarlet; and Député Sadize, purplish scarlet. Six large double Fuchsias are Mrs. H. Cannell, Avalanche, Sir Garnet Wolseley, Miss Lucy Finnis, Marksman, and, having the largest flowers of all, Champion of the World.

PIPING REQUIRED FOR SPAN-ROOFED HOUSE (Crust).—You do not give the height of the house, but we conclude from the width that it will be about 9 feet. About 44 feet of 4-inch piping will be required to maintain a greenhouse temperature, and a length of 90 feet to secure stove heat.

WORMS (R. T. F.).—We know of no trap for them. A poker thrust into the ground and moved backwards and forwards will bring them out of their holes.

ANTS (M. E. P.).—You may drive them away by sprinkling Scotch snuff over their haunts, and repeating the sprinkling until they depart permanently.

NAMES OF PLANTS (P. M.).—A variety of *Aspidium aculeatum*. (Mrs. Holmes).—1, *Iris sibirica*; 2, *Arnica montana*; 3 and 4, *Astrantia major*; 5, *Veronica Teucrium*. (Juvenile).—*Metrosideros tomentosa*. (A. C. B.).—*Cornus sanguinea*. (G. O. S.).—1, *Geranium striatum*; 2, *Erigeron bellidifolium*; 3, A species of *Sidalcea*; 4, *Ranunculus acris*. (W. L. L. H.).—1, *Helichrysum marginatum*; 2, A species of *Heuchera*. (F. Taylor).—*Stanhepa tigrina*. (W. D. H.).—*Spiraea Filipendula*, Dropwort. (W. D. H.).—*Spiraea Filipendula flore-pleno*. (B. Smyth).—*Tilia europaea*, *l. laiciatis*. (W. H. Manser).—We cannot name the Rose, but we think you have been misinformed as to its origin. Make further inquiries on that point and inform us of the result of them. (R. B. L.).—We regret that we cannot name the Rose.

POULTRY, BEE, AND PIGEON CHRONICLE.

A BATCH OF SCHEDULES.—PART 1.

THEY certainly are coming on thickly. We never remember a longer list of forthcoming meetings, and nearly every schedule which comes to hand has some peculiarity. It is either fearfully behind the times, or gives some class which is not commonly found, or has a preposterous entrance fee, or holds out some bait to trap unwary exhibitors. We have a very large bundle before us; some great cumbrous sheets, others elegant little pamphlets with pink or green covers, on which are engraved a happy farmyard family or an impossible-looking Cochin, or a Poland with a wooden sort of appendage upon its head to represent a crest.

Picking out some of the best got-up of these schedules we find a few facts worthy of note, and in mentioning them we do so more to show any peculiarities than to give a general sort of *rechauffé* of the whole. We will take them in no order, but select from a batch which the last fortnight's post has brought to us.

On the top we find, in a cream-coloured cover, the schedule of the first meeting at Cardiff. To be held in the Drill Hall, when the Rev. G. F. Hodson will award the prizes. There are fifteen silver cups or pieces of plate, and we find one of them is for Sultans. This is something novel, and we wish the new venture much success, and hope it may tend to finally prove whether the breed should be bearded or not. Black Cochins here have a class, and Malays two classes, both of which facts their breeders should note. Next in order comes Whitechurch. This Exhibition is to be held in connection with the agricultural show, and we find on the Committee of five three such well-known names as Messrs. Tadman, Darby, and Etches. The Judges again are announced—viz., Messrs. Dixon and Lane, the latter for Game and Bantams. There is one chicken class, but the other classes are all "for any age." We wonder Mr. Darby allowed the Polands to go to the Variety class.

On the same days as the last-named comes the Cambridge-shire Society's meeting at Ely, where the wife or daughter of a tenant farmer in the said county has only the opportunity on this occasion of winning Lady Elizabeth Adeane's annual donation. No Judge's name is announced, but we imagine, all well, we shall find Mr. Hewitt here. In the schedule nothing calls for much comment. Leghorns have a class, but the rest of the breeds are not well subdivided at all. On July 19th there is to be a Show at Bedford. The schedule is in many ways very fair. Game have four classes, one of them being for single cocks. White Cochins have also a class, and there is a £5 5s. cup for the best pen in the Show. Mr. Tegetmeier is to judge. There are also some good local prizes with another £5 5s. cup. Next the schedule for Ormskirk is good. There are prizes for chickens and adults. At this time of the year, and for the next two or three months the awards in old birds are mostly mere lotteries, for the birds in the best plumage generally win before others in ragged feather of however much merit when in full condition they may be. Here there are two classes for White Dorkings, which are in honour of Miss Fairhurst we should imagine. We

are surprised to find at so important a north country show no class for Black Hamburgs. Game and the Asiatics are well provided for. The Pigeon classes are very numerous, but a "note" says "no third prize will be awarded unless there are five entries." Oswestry once more puts forth its annual *menu*, and really in mere charity some Salopian fancier should try and make this Society wiser in its generation. The schedule has been the same for years, and in many classes the classification is positively ludicrous. Class 14 is for Game Bantam chickens, while there is nothing in the schedule whatever to prevent Game Bantams winning again in Class 15. White Cochins, too, are classified with Buffs, while Houdans come after any other variety not mentioned, as if they were something quite distinct from what has preceded them.

It is refreshing to turn to Hereford, where we find well-known fanciers on the Committee and the prizes good. There are two point cups here, where a cup bird counts ten, and so on in gradation till a commended bird gets the modest number of one. There are also ten others besides these two point cups. The prizes are good and the classes well classified on the whole. There are two chicken classes, but we are told that chickens are also eligible in all the other classes. The entry fees are low, but we can find no Judges' names. Rule 20 states, "Exhibitors will have a ticket of admission to any part of the Society's show-yard." The next prospectus in our pile is of a humbler nature, but none the less interesting; it is that of the Warminster Cottage Gardeners' Society. Under the able Secretary, Mr. Hinton, the schedule is much improved both in poultry and in Pigeons, and many chicken classes are added; pens, too, this year will be provided, the Judge remaining as in former years, and being Mr. Sainsbury of Devizes. Another nice little local show follows in its wake, that of Malton and district in Yorkshire, where we find among many useful classes one for Silkies. We notice it with undisguised pleasure, and beg all exhibitors of the breed to patronise this attempt to popularise a most elegant and useful variety. The classification does the Committee credit, and though the prizes are small we venture to think the entries will be large.

Chesterfield is its successor in our packet, and it is but meagre. The name of the Judge (Mr. Teebay) will have more power in making entries than the classification we should think. On the Committee is Dr. Holmes, who is, we believe, an energetic poultry fancier, and will probably see to the welfare of the specimens. Malays have a class, and there are five pieces of plate to be awarded. The next on the file is very modest, but we mention it as being a means by which the clergy and squires of country parishes can promote the love of poultry in their villages. From actual experience we know the love of flowers, birds, and animals keeps big lads and young men in their homes instead of standing at road corners or frequenting places even less worthy of resort. This little list has only five classes, and our great breeders will perhaps sneer at it; but we wish the Rev. E. N. Thwaites of Fisherton near Salisbury much success, and feel sure the same reward for good will attend this new venture of his as has ever attended all those other manifold attempts for the good of his parish, and we beg others to try and do as he has done.

We end Part I of our batch with just a line or two upon two shows in prospective—viz., Ramsgate and Ipswich. For the former we learn good and competent Judges have been engaged, and the prizes are to be most liberal—namely, five in each class of the value of 42s., 30s., 20s., 15s., and 5s., while the entry fee is only 5s. per pen. We do not think such a schedule has ever been before attempted. And then lastly one word for Ipswich. We hear from our worthy friend, the Stoke Park manager, to say that he has consented to be the Secretary, and telling us of lots of dainties which he is providing for the poultry world's benefit. Among them the Show is to last but two days, none but single birds are to be shown, and the judging is to be performed by amateurs, one of whom is the Stowmarket hero for Game and Game Bantams. We wish Mr. Wragg much success, and hope many fanciers will help him with donations or cups to build up under such an excellent leader a show worthy of the breeders of the eastern counties. This schedule will, we hope, be fully described in our second "batch," with many others of much interest.—W.

CHELMSFORD POULTRY SHOW.

THIS was held in connection with the Essex Agricultural Society's Show on the 4th and 5th inst., when the following prizes were awarded.

POULTRY.—DORINGS.—Coloured.—Cock.—1 and Cup, F. Parlett. 2, H. Lingwood. 3, H. Allen. Hen.—1, Cup, and 3, Rev. H. R. Peel. 2, F. Parlett. Any other variety.—Cock.—1 and Cup, O. E. Cresswell. Hen.—1 and Cup, O. E. Cresswell. 3, E. Snell. COCHINS.—Buff or Cinnamon.—Cock.—1 and Cup, S. R. Harris. 2, Lady Gwydyr. 3, Mrs. A. Tindall. Hen.—1 and Cup, C. M. Stackings. 2, A. E. W. Darby. 3, Mrs. A. Tindall. Any other colour.—Cock.—1, Cup, and 3, Mrs. A. Tindall. 2, F. H. Jennings. Hen.—1, Cup, and 2, Mrs. A. Tindall. 3, A. Beaumont. BRAHMAS.—Dark.—Cock.—1, Horace Lingwood. 2, Mrs. A. Tindall. 3, Lady Gwydyr. Hen.—1, Cup, and 3, Horace Lingwood. 2, E. Pritchard. Light.—Cock.—1 and Cup, Horace Lingwood. 2, F. Haines. 3, Mrs. A. Tindall. Hen.—1 and Cup, Horace Lingwood. 2 and 3, F. Haines. GAME.—Black or

Brown Red.—Cock.—2, S. Matthews. 3, C. Rowley. Hen.—1 and Cup, S. Matthews. 2, E. Pettitt. Any other colour.—Cock.—1 and Cup, S. Matthews. 2, H. W. Peck. 3, W. Jefferies. Hen.—1 and Cup, S. Matthews. 2, T. Docwra. 3, E. Winwood. HAMBURGS.—Gold and Silver-pencilled.—1, W. K. Tickner. 2 and 3, E. Snell. Gold and Silver-spangled.—1, J. Rawnsley. 2, J. Long. FRENCH.—2, E. Snell. ANY OTHER VARIETY.—1, T. Norwood. 2, J. Long. 3, G. W. Boothby. BANTAMS.—Game.—1, W. Adams. Any other variety.—1, L. J. Morrell. 2, Ludlow & Backham. SELLING CLASSES.—Cock or Drake.—1, Duchess of Hamilton. 2, S. W. Hallam. 3, W. Tippler. Hens or Ducks.—1, Mrs. A. Tindall. 2, Rev. H. R. Peel. 3, T. Docwra. COTTAGERS' CLASS.—1, R. Brown. 2, T. Pitts. 3, J. Burrell. DUCKS.—Aylesbury.—1, J. Hedges. 2 and 3, E. Snell. Rouen.—1, H. Dowsett. 2, E. Snell. 3, F. Parlett. GESE.—1, J. Everett. 2, E. Snell. 3, W. Tippler. TURKEYS.—1, Mrs. Mayhew. 2, E. Snell. 3, W. Tippler.

BARNSTAPLE POULTRY SHOW.

THIS Show was held in the Market-house, and the entries in many classes were large. Mr. Dixon of Bradford made the awards, which were favourably received. *Malays* with seventeen pens opened the catalogue. Many of the birds were rapidly losing their feathers. We liked the first pair very much, and the second contained a well-made pair of birds standing well on their legs. The first Black Red cock was a stylish bird, with a good hen as companion; the second, too, were of good colour and shape. *Brahmas* had one class of fourteen pens, the Dark being perhaps the best in quality. *Cochins*, again, were all classified together. We saw some good Buffs and a pair of Whites. *Dorkings* were rather out of feather. We liked the colour of Mrs. Radcliffe's third-prize cock; he appeared, however a little leggy. The *Hamburgs* mustered well. The first Pencilled (Barter) was a good hen, her markings clear and distinct. In the Spangles we thought the Silvers the best. The first hen had good spangles, and the cock was very fair in sickles; but Mr. Harris won with his least esteemed pen we suppose, for his winners were in at 90s., while £10 was the price on his second-prize pen. *French* made only half a dozen pens, among which we saw an excellent pen of Crève-Cœurs. An immense class there was of *Minorcas* and *Andalusians*, no less than a score of pens. The first-named showed up in the greatest numbers, and the winning birds were apparently well selected. *Spanish* mustered only seven pens, where a Cornish fancier for once was victorious over celebrated Bristol. The winners were fairly smooth in face and good in combs. The Variety class was truly a beautiful collection. There were seventeen pens, and nearly all of merit. The first went to fine White-crested Polands. The cock was, we think, the first Palace bird, with a young hen which we have never seen before. There were other good Polands in the class, Black Hamburgs, &c., and though the Judge had four prizes to award we think he must have had plenty to do to choose them wisely. *Game Bantams* made also a score of pens. The winning birds were certainly smart in heads and carriage, but we fancy there has been of late a great inclination to coarseness and to too large size in the breed. Many birds seem to be losing that gracefulness which we used to see more often. In the Variety Bantam class of ten pens the Black Rose-combs were excellent and the winners well placed. The *Turkeys* were only three pens, and *Geese* four. The first pair of *Turkeys* (Heal) were entered only for 60s., and were of no very great merit. *Ducks* were all classed together. We noticed a fairly good pen or two of Aylesburys. Two large single-bird Selling classes ended the list, where over seventy pens, in value from 20s. to 12s. 6d. per pen, competed for half a dozen prizes. We daresay many pens were claimed, but such classes can only depreciate the value of fancy poultry, and do but little good.

VISIT TO MR. H. M. MAYNARD'S PIGEONS,

HOLMWOOD, RYDE, ISLE OF WIGHT.

PART I.

THE name of Mr. Maynard has during the last few years steadily advanced in the prize lists of our great shows. Taking up the fancy some ten years since he attached himself to Carriers especially, then he took up Barbs as a second horse, while other Pigeons have followed as favourites with him. Success at small shows led, as usual with a persevering fancier, to at first little notices and minor prizes at large exhibitions; then, as now, to many first and second prizes at the great shows. At this present time the name of Maynard is well known to all Pigeon fanciers, and is a terror to exhibitors. Maynard's birds are looked out for at our shows and are objects of much notice and admiration. As a conclusive proof of Mr. Maynard's success with Carriers, I

may state what is well known in the fancy, that he sold his champion Carrier cock recently for £100, and was rather sorry to let him go; while he sold a pair for £180. But to proceed in order. I had for some time past known that at Holmwood there was a stud of four hundred birds exclusive of feeders, of which latter it may be remarked Mr. Maynard makes but little use. I was naturally anxious to see such a stock of birds. However frequently one may see a fancier's birds at shows, there is always an additional pleasure in seeing them in their own lofts where they were reared and where they live, to notice the style of lofts, what their arrangements, what plans are found to succeed, what nest-boxes used, &c.

Mr. Maynard lives in the Isle of Wight, not a convenient place for an exhibitor when one remembers that shows take place in the winter, and birds must have a sea passage as well as a land journey. I never wonder that so many exhibitors are in the north and manufacturing districts, for there is such a network of railways. It is only just to have the birds carried to the near station, and away they go to this show and to that show. Then still less do I wonder that there are so many exhibitors near London, because Pigeon-fancying requires but little room, though the birds are better for much room; and then London shows are now the shows, and probably, remembering the convenience of the Aquarium, will become more than ever the shows for the upper-class and larger-stocked fancier. But the Isle of Wight is not only distant, but there is the stormy Solent, often very stormy in winter, to be crossed by the tender high-class birds. Genuine must that fancier's love of birds be to face such a drawback. However, the climate of the island is all that can be wished.

Last Crystal Palace Show Mr. Maynard kindly invited me to come and see his stock. More than once I had been on the point of going, but was hindered. After all it was well I had been prevented, for even May was this year more than usual "a fine month spoiled by east wind," and as to the poet's May, that of poor deluded Thomson, we know another and a better poet, Tom Hood, said of Thomson's "gentle spring, ethereal mildness," "there's no such season." But June, leafy June, is all happily different. It was a glorious day when I started for the Isle of Wight. One felt thankful to live to see and feel such weather. Along the line, *via* Salisbury, the hay harvest was in progress, then further by damp water-meadows where the Heron was standing sentinel-like and demure on the banks, and the Moorhen, that joyous, light-hearted little bird, was now on land, now in the water. Stokes Bay, the place of embarking for Ryde, is at length reached. Oh! the bright clear sunny water of the Solent, alive with white-sailed yachts! The sea here seems unsoiled by trade or commerce—a pleasure sea, nothing to mar the joy save forts rising here and there wart-like and ugly out of its surface, which tell of war-possibilities and wounds and death. Ugly forts! May never necessity arise for their use; 'tis bad enough that they should spoil the look of the sea. A half an hour's sail and we reach Ryde pier, far stretching-out into the shallow water, and then a long walk on its resounding boards and we are in Ryde itself, where I find Mr. Maynard ready to receive me and drive me to his home some two miles distant. Straight on through clean pleasure-looking Ryde, through Union Street, which is its Regent Street, and indeed the shops might make at any rate a Bath tradesman jealous. On, still climbing. Oh! the Isle of Wight is a perfect purgatory for horses. None but the vicious and over-spirity ones should go there. Kindly, good, gentle horses for flat country; but the ungentle should be threatened with, not "I'll send you to Coventry," but "I'll send you to the Isle of Wight, that I will." If horses ever take to literature I shall expect to see on the railway stalls a book with such a title as this, "Life and its Misery, by an Isle of Wight Horse." Still climbing, passing pleasant villas and neat cottages, when a halt and we enter a gate, past a thatched lodge, and dipping our heads to avoid the pendulous leafy boughs, we drive up an approach, and presently reach a country house which stands out white and clean from the trees around. This is Holmwood, where Mr. Maynard's family have resided for many years. I am first taken out to the front lawn, from which are peeps of the Solent and the coast of Hampshire beyond. We are high above Ryde, but the planting has been so managed that we see nothing of the town, only the sea and the shore opposite. Pleasant this for a town; a new one especially is never picturesque as seen from a country place.

Having enjoyed and admired air and scene, I am next taken to a wood at the back of the house where are numerous wire-haired terriers. These Mr. Maynard and his clerical brother who accompanies us (brother fanciers as well as brothers are the two), keep in considerable numbers, both from liking the breed and because they protect the fowls and Pigeons from rats. No rats can have peace where the ever-worrying, worrying, restless, wire-haired terriers abound. I was glad to see this breed of dog, bred to points and at the same time not crossed by his smooth cousin. The wire-haired is, I believe, the original English terrier, his thick felt-like coat enables him to face weather and not shiver like the modern fox terrier. I have a

lively recollection of some charming terriers at Holmwood. There were several litters of pups, some pure white, others with the more general dark ear and eye. Keeping this class of thorough vermin-hating dogs with poultry and Pigeons is a point. N.B.—Remember this, ye fanciers who are troubled with and are sufferers from rats and weasels and the like "small deer." The dog kennels scattered here and there in the wood had a pleasant appearance. Here a mother asking for notice, and for her pups to be inspected and admired; then another a little way off asking with bright eyes and wagging tail for like favours. These terriers are about the best of their variety in any numbers that I have seen for some years, and as a defence against rats in somewhat rambling poultry and Pigeon places are well chosen. Some of the dogs will no doubt come another day to the front at our exhibitions.

Turning from the dogs I am called to notice some Black Red Game fowls and some Black Hamburgh chickens. How attractive after all and unequalled in colour and symmetry are the Game. Other cocks may be pretty, but the Game cock is far beyond that. Other hens may look domestic and motherly, but the Game hen is beyond both. A door is opened and we reach the Pigeons.—WILTSHIRE RECTOR.

THE RIGHT KIND OF POULTRY FARM.

A CONSIDERABLE number of trees for shade and shelter from rain (for it is not desirable the fowls should be forced into the houses in rainy weather) are needed, and crop-bearing trees would be necessarily selected, which should not only shelter the birds but at the same time yield a considerable return of their own. Apples, pears, plums, and cherries would probably be the standard trees; and a clump of filberts should also be in every run, to afford better shelter than standards would give. In this way alone at least 5 per cent. on the capital would be obtained, which only assumes 30s. worth of fruit from each half-acre run. We may be asked "Who is to think of all these things?" We reply that if poultry farming is ever to pay it must be conducted like every other kind of wholesale business, and every possible thing must be thought of by which returns may be increased or expenses may be saved. It is by reducing everything to well-ordered system, in which everything necessary is done at the smallest possible expense—or, to put it in a plain way of our own, in which capital is freely employed to save expenditure of revenue—that the leviathan establishments which are the pride of civilised nations have been built up and yield the large revenue which they do to their princely owners: but the difference is this, that while the perfect system in these giant manufactories has been slowly matured, and is the perfected product of long experience, in poultry farming on a large scale we have no successful experience to fall back upon. Such experiments as have been made were failures; and it is therefore all the more necessary to supplement such a want by the most anxious thought and care regarding all details which can bear upon the result.—(*The Illustrated Book of Poultry*.)

THE ANGOLA RABBIT.

THE Angola or Angora Rabbit is a native of France and midland portions of Europe, where it flourishes in abundance. In England, however, it has never been a great favourite, presumably owing to its requiring rather more attention than most other foreign varieties.

The Angora is a fair-sized but not a very large animal, unusual size being generally indicative of impure blood, although there is considerable variation in this respect. The animal is generally small-boned and rather delicate in appearance. The fur is long and fine, being more like wool than hair, and quite unlike the orthodox covering of the Rabbit kind. In good specimens it lies along the body in frills or curls, the appearance being very handsome. The ears are short and erect, but not so stiff or strong as in the case of Silver-Grey or Himalaya Rabbits, and in some cases the ears are inclined to be pendant, although the less they are so the better. The head is rather small, but the forehead is prominent. The general appearance is neat and delicate. The chief point of excellence is the wool, which varies very much in strains. The long, soft, and curly variety is certainly the one most admired, and the finer the quality the better. Long, straight, and coarse hair, however it may lie in profusion, is never liked so much as the finer variety.

It is necessary to keep the Angora in a warm and dry hutch, and to subject it to periodical combings, or the wool will become matted, and nothing but the next moult will bring it right.

Mr. Rayson remarks that if the wool does not become matted it is not of the fine nature so admired, and he is quite right. The coarse and straight wool but seldom mats, while soft and fine curly wool rarely remains clear unless combed and kept clean. There need be but little trouble if the matter be properly attended to, but if neglected a free cropping will often be necessary before the animal can be made to look correct. It is strange that a little more is not done in the way of preparing

these animals when sent to exhibitions. Ten minutes' brushing will make a great improvement in their appearance. It is well not to put hay into the hamper, or the seeds will stick in the wool, and if you are not on the show ground to brush them out will detract not inconsiderably from the beauty of the Rabbit.

The colour is usually white, although coloured specimens are occasionally met with. These, however, are not generally so profusely covered with hair, nor is it of so fine a nature. Black, black-and-white, blue, blue-and-white, grey, and grey-and-white are the usual self and broken colours, fawn and fawn-and-white being very rare. We do not recollect having seen a tortoiseshell, a colour that the long wool would be hardly suited to show off to advantage. Winners are sometimes met with of a broken or dark self colour, but most of the successful animals are pure white, the colour which seems naturally to be most fitted to exhibit the lustrous nature of the wool. Still, a well-marked coloured one is rare, and hence to be admired and prized.

As a rule they breed very true to colour, and when a little coloured blood has been admitted into a white strain it seems almost impossible to eradicate it. It is worthy of notice that the most successful strain extant is pure white, long in the wool, curly, and with ears moderately short and slightly inclined to be pendant. The specimens of this strain are generally of pretty good size. The Angora is exceedingly delicate, and requires a little warmth in order to keep it in good condition and to bring its wool into good form, otherwise it will but seldom attain a good size, nor will the wool be as fine as can be wished. Too much warmth will make the ears too long and lopping, so that it is necessary to use a good deal of discretion in the question of heat. As a rule it may be said that the air should be kept at a genial temperature, with a copious supply of fresh air. In disposition the Angora is extremely gentle. Instead of fighting right and left when in company members of this variety will generally fraternise, and with a few exceptions will not fight,

Fig. 15.—THE ANGORA.

especially does; the bucks, though not so quiet, being still considerably more so than those of most breeds.

The doe is fairly prolific, the litters occurring frequently, and five or six being the number generally brought forth. The doe will tear the wool off her chest, often laying herself perfectly bare, and of necessity spoiling her appearance, so that exhibition does must not be worked as breeders. The best age for showing is about a year or eighteen months, the wool seldom attaining its full length or fineness before that time. The young are born quite bare and perfectly pink. At the end of the first week they begin to show a little white down, which increases in length and thickness with age until when the animal has attained the age of a month it is nicely covered. The young are delicate, and a warm and dry hutch is absolutely necessary.—GETA.

THE ALEXANDRA PALACE AND MALAYS.—The Committee have offered £4 towards the Malay prizes. I have undertaken to try and collect sufficient to make prizes for the class, £3, £2, £1, and 10s. I shall be grateful for any help from Malay-breeders. The following have already promised or sent the money:—Mr. E. Stanley, 10s.; Mr. S. B. Perry, 7s. 6d.; Mr. R. Hawkins, 2s. 6d.; and 5s. from—JOSEPH HINTON, Warminster.

VERMIN ON POULTRY.

JNO. E. ROBERTS, in the *Southern Poultry Journal*, says:—“Many fanciers use the carbolic (or carbolated) powder in order to rid their fowls of lice and mites. It is considered the very best of remedies. My plan is one which I think is used by no other breeder, has never failed me in completely ridding my fowls of every insect, and has demonstrated to me its infallibility. It is simply the use of oil of sassafras mixed with sweet oil. To 1 oz. of oil of sassafras put 5 or 6 of sweet oil, and apply

a small quantity to different parts of the body of the fowl, selecting those points where the vermin would be most apt to hide.

“In applying the preparation I fill with it a small oil can, so that I can force out as much or little of the oil as I wish. A very small bit can be made to go a great way, for one drop can be rubbed over 2 or 3 inches of space, and is no more trouble to apply than the various insect powders. I use sweet oil because of its curative powers, but any kind of grease, no matter what, will do to mix with the oil of sassafras. The oil of sassafras is the eradicator, the other oil merely the vehicle. I believe common sassafras tea would be wonderfully efficacious.

“Make it in a large pot, then after allowing it to cool dip the fowls in bodily. In one second the lice will be dead, and in ten seconds the fowl will be perfectly dry if placed in the sunshine. It is hard to form an idea of the magical effect produced by the oil of sassafras. I have never tried the remedy in greater attenuation than that mentioned (one part to five or six), but believe that it would be equally good if composed of 1 oz. oil of sassafras to ten or twelve of any other oil or grease.”—(*Rural New Yorker*.)

BEEES PIPING.

The question of piping is fully discussed and explained in “Bevan on the Honey Bee,” and I can fully corroborate all that is there advanced upon the matter. Bevan says, “It is now, however, ascertained beyond a doubt that the sharp clear notes uniformly proceed from a princess that is at liberty, and that the notes which are uttered in a hoarse key as uniformly proceed from one that is still imprisoned.” Old queens never pipe, and where several young queens are being raised it is only when the bees wish to swarm that piping occurs. When the bees do not wish to swarm the eldest of the young queens is allowed to emerge from her cell on arriving at maturity, and is permitted

to attack and destroy her rivals who are still in their cradles. This is at any rate usually the case, though sometimes a second young queen is permitted to escape, and a duel then takes place between the aspirants to the throne.

Some years since an account appeared in your Journal of what I witnessed in my unicombe hive. The eldest princess when at liberty constantly attempted to gain access to the cells of her rivals, and was as constantly repelled by the workers who had charge of the imprisoned queens. If she came near to the royal cradles the workers seized her by her legs or wings and speedily compelled her to retire. She would then begin to pipe in a clear shrill note, and the imprisoned queens responded in hoarse, dull, short notes.

About a fortnight since the eldest princess in one of my hives began piping in a hoarse note before she had obtained her liberty, and, as I predicted, the following day sharp clear piping was audible, showing that she was at liberty, and I could hear two imprisoned queens responding in hoarse notes. Wishing to save the queens without allowing the bees to swarm I opened the hive and removed two royal cells, the only sealed ones which I then discovered, and the young queens were introduced to queenless hives and were well received. I saw the queen which was at liberty, and heard her pipe while the comb was still in my hands. Next day piping was still going on in both keys, and after some trouble I discovered another closed royal cell. This I opened and allowed the queen to walk out; she was then introduced to a swarm in my unicombe hive. Piping in a shrill note continued in the parent stock during the remainder of the day, but there was no response, as only one queen then remained in the hive.—J. E. BRISCOE, *Abington, Wolverhampton.*

CRACKED EGGS.—It often happens that valuable eggs get cracked in the nest, or before putting them under the hen, or in the incubator. Such may be saved by the application of a little mucilage or liquid glue with a camel-hair brush over the crack, and then rolling the egg in fine plaster of Paris.

TURNING OUT BEES.

Last year I made what Mr. Pettigrew calls a "turn-out," but was disappointed in finding a considerable quantity of young brood in the combs of the old hive. What was the reason of this? The hive swarmed on the 10th of July, but the bees returned and swarmed again on the following day. Twenty-one days after (August 1st) I turned the bees out, and found several combs containing brood varying from the egg to the stage when the brood is still white. According to Mr. Pettigrew there should have been none in the combs but some drones nearly matured. The bees had been hanging out about a fortnight before they swarmed.—C. S. MILLARD, *Notts.*

[We are obliged to Mr. Millard for the above communication, for it gives us an opportunity of explaining what may occasionally happen in an apiary. The brood, or some of it, which was found on the twenty-first day after swarming was, we imagine, about six days old, for the brood of working bees is sealed over when it is from eight to ten days old. The young queen had begun laying about the fourteenth day after swarming. Queens are fourteen days in their cradle cells, and generally speaking begin laying from eight to fourteen days after being hatched. In trying to explain the mystery of the case before us we shall give two reasons why young brood was in the hive. One is that the queen which commenced laying so soon after the hive had swarmed was perfect and ready to burst out of her cell at the time of swarming. A matrimonial alliance may have been effected three or four days after her birth. It is just possible that both of these events happened, and that the queen commenced laying at an early day. These things come within the circumference of possibilities, though they rarely happen, for it is very unusual for bees to permit young queens to be perfected before the mother queen leaves the hive with the first swarm. If weather prevents bees from swarming (first time) till the young queens are approaching maturity they are torn from their cells and cast out of the hive dead. It is rare indeed that bees allow young queens to come within forty-eight hours of the time of their maturity while the mother queen is in the hive.

The second reason we have to give of the brood being unusually early is probably the right one. No history of the queen that went with the swarm has been given; nothing has been said of her doings either before or after swarming. Most likely she was sister (not mother) of the queen left in the hive, both having been produced from the eggs of the old or mother queen, which died about fourteen days before swarming took place. On the supposition that the old queen died when the bees began to cluster outside, it will be observed that swarming took place and egg-laying commenced at the usual times or in the ordinary course of events. All is natural and common on the supposition that the old queen died before the bees swarmed, and this is not an unusual occurrence. In such cases swarming is postponed till the young queens arrive at perfection, when "piping" commences. If we had seen the hive at the time we could

have told with certainty whether the old queen had died or not before swarming. The turning-out process is a useful one, and twenty-one days after swarming is the right time for it. Mr. Millard may turn out bees for as many years to come as we have done in the past without finding another case so exceptional.—A. PETTIGREW.]

OUR LETTER BOX.

GUINEA FOWLS (G. P.).—The time required for incubation is from twenty-eight to thirty days.

HONEY REMAINING IN CELLS (H. T.).—The pressure of the air keeps it in. If there were a small hole made through the bottom of the cell the honey would flow, for then the pressure of the air would be equalised at each end, and the gravity of the honey would cause it to flow. There is a slightly elevated rim round the mouth of each cell, which rim also helps to retain the honey.

ARTIFICIAL SWARMING (Rose).—You have done well to swarm your bees artificially, and thus prevent them from wasting their time in clustering about the door of their hive. The swarm we think will be strong enough without the bees of the old stock, though doubtless they would make it stronger. If the stock is heavy now you might succeed in getting another bar-frame hive filled by driving all the bees of the stock into it on the twenty-first day after swarming; and if you take the honey in the autumn from the other hive, which you have supered, its bees could be united to the second swarm or turn-out. Thus two hives of honey and the super and two good stocks of bees would be obtained. Dahlias are not hurtful to bees. Your success this year will give you courage and confidence amongst your bees.

FLIES IN ROOM (Musca).—Burning coarse brown paper in a room drives some out and stupefies the remainder.

REMARKS.

- 4th.—Morning rather grey; fine at midday, and pleasant throughout.
5th.—Fine morning; showers during the afternoon, and heavy thunder between 6 and 7 P.M., with heavy rain and some hail.
6th.—Fine morning; rain at noon; thunder in the afternoon, but fine night.
7th.—Fine all the morning; but severe thunderstorm and heavy rain at 8 P.M.
8th.—Fine morning; sharp shower at 1 P.M. and again at 6 P.M., but fine afterwards, though cloudy at night.
9th.—Fine morning; rather stormlike in the afternoon, but soon passing off, and fine night.
10th.—Very fine all day and very warm.
Much cooler than last week, with somewhat frequent thunder. The very low grass minimum on the 4th was due to the heavy fall of hail on the previous evening.—G. J. SYMONS.

COVENT GARDEN MARKET.—JULY 11.

OUTDOOR fruit is now beginning to put in an appearance, but showing at present a light crop and making good prices. Trade for best goods brisk.

From observations taken near London during forty-three years, the average day temperature of the week is 74.7°; and its night temperature 50.7°.

DISBUDDING ROSES.

Do we exhibitors—amateurs I mean, for I do not of course presume to speak of or to discuss the practice of the profession—do we disbud our Roses too freely?

This is a very important question, and now that the shows are over—for before these notes are printed the last show of the year will have been held at the Westminster Aquarium, and the great nurserymen will all be hard at work budding, and the pressure on your space will be much lessened—now is a good time to discuss it. The question occurred to my mind as I read “*D., Deal’s*,” account of the Rev. W. F. Radclyffe’s Roses, and the force of it has been increased by two visits I have lately paid, one to a nurseryman’s and the other to an amateur’s garden.

“*D., Deal*,” in speaking of his visit to Okeford Fitzpaine, says, “My friend never exhibits and never disbuds;” and then he proceeds to name certain varieties which were splendid. He especially names Charles Lefebvre, saying how beautifully the petals were shaded with velvet of a darker colour. With the exception of some blooms of Mr. Baker’s I have not seen this Rose really good this year. Certainly I have not had one good bloom myself and I have fifty plants, and I can remember quite well that the year I commenced growing Roses how fine this Rose was on the Manetti, and then I did not disbud. I think Canon Hole describes this Rose or Lord Raglan, I am not sure which, but the description is so beautiful and appropriate to Lefebvre that I prefer to claim it for that lovely Rose—“The colour is exactly like a sunbeam in a goblet of Burgundy;” and since the first few years of my growing Roses I have never seen that variety so nearly come up to this description as it did then. Of course I am open to correction, indeed to annihilation, when I ask, Can disbudding be carried to too great an extent? and I answer it can in my opinion and often is.

Now, there are two kinds of disbudding—first, the thinning of shoots; and secondly, the rubbing-out of the side buds and of the buds all down the shoot, so as to drive all the sap and strength of the plant into one bud. In some large nurseries which I will not name this is done to an enormous extent, and the results certainly are splendid blooms of extraordinary size, but when these are cut all further blooming of these plants for this season is over. Of course this is not of the slightest consequence to the great nurserymen, who as soon as the shows are over care not for blooms, nor indeed have time to think of anything but budding; but it is a very different thing with amateurs.

Let me state my own case. On the day I cut for the Crystal Palace—viz., the 23rd of June, I was not able to cut a single bloom in my front garden. On the 5th of July, when I staged for Hereford, I only cut three blooms (in the front) of Hybrid Perpetuals. Between the Alexandra Rose Show and the National—i.e., between the 29th of June and the 4th of July, the blooms on my front

came and went. They are now completely over. For Clifton-to-night I did not cut any blooms but Teas and one solitary bloom of Mdle. Marie Cointet. Not one week out of the fifty-two did my blooms last. And what is the reason of these short-lived blooms? I answer, Disbudding and excessive forcing.

As I looked over my front to-day I could not help asking myself, Have I not been a little selfish? For fifty weeks in the year the whole of my front has looked hideous; nothing in the shape of a flower. Roses growing in lines on terraces one below another, next a blaze of colour for one brief week, and then the same monotonous sight again. “Second blooms,” some one may exclaim; “what of them? Won’t you have numbers of them?” Second blooms, I answer; what of them indeed. Let me quote once more our President’s words—“They are but the gleanings of the Grapes, the echo of the chorus.” Where they do come they are scarcely fit to be called Roses, and they do the plants no good. Now, if I had not disbudded so much all the side buds would follow after the central blooms and still make the garden gay, and give poor Mrs. Savage something to look at and some blooms to cut for her drawing-room, but now there literally is not a bloom, except, always excepting, the lovely Teas. This is, of course, to a certain extent a sentimental reason, but certainly it is an unselfish one, and should have a certain weight.

But I now come to a more prosaic question. Is so much disbudding really necessary? Cannot good show blooms be obtained without it? I almost tremble as I write No to the first question, and Yes to the latter. But I do still assert my conviction that fine blooms can be obtained from plants which are left to grow naturally; and why do I say so? Because I have seen them. Let me now say where.

Mr. Walters is a nurseryman at Exeter from whom I buy many Roses every year. He is one of the best rosarians I know. He also supplies Mr. Baker with the main portion of his plants. He grows splendid stuff; he works his dwarfs very low, suckers from his plants are unknown, and he buds them all himself with the assistance of his sons; and in July his nursery is one of the grandest sights I know. His blooms are always good and very often superb, and he never disbuds. Mr. Baker and I have pressed disbudding upon his notice, entreated him to practise it, but he only replies, “I can get good blooms without. I can sell all the plants I can work without going to exhibitions, and I like to have blooms to show my customers when they visit me.” And so he always has, and wonderful good blooms too.

The other place I visited was of quite a different order. In Lyme Regis a little above the town is situated the vicarage house belonging to the Rev. Dr. Hodges, who is exceedingly fond of Roses. He cultivates these not largely as exhibitors would consider, but very largely for a man who thinks only of garden decoration. He asked me to go and see his Roses, and though I could ill spare the time I did so, and so pleased was I with what I saw that I was very glad I had gone. In this lovely garden on

terraces sloping towards the east are beds of standards and dwarfs beautifully laid-out and planted—garden decoration being the only object in view; but the blooms were so fine that I persuaded Dr. Hodges to let me show a box for him at Clifton, and went over myself and staged them for him. Many of the blooms I saw were as fine or finer than any I have had this year, and yet he never disbuds; I believe he would think it sacrilege to do so. He positively shuddered as I proposed it to him.

Here, then, are three cases—Mr. Radclyffe's, Mr. Walters's of Mount Radford, Exeter, and the Rev. Dr. Hodges's of Lyme Regis. All grow splendid flowers, and none disbud. It seems to me, then, that it is evident that good blooms can be grown without excessive disbudding.—WYLD SAVAGE.

FERTILISERS AND THEIR APPLICATION.

ON the face of it the excellent letter of "J. B. K." on page 33, criticising the mode I detailed of applying fertilisers to garden crops, appears to possess crushing force. It is a common saying that figures when put clearly cannot be "got over." I have no occasion to attempt to "get over" the figures of your correspondent, because he has left ample room between them. We sometimes see allusions made to reading between the lines. I am now going to indulge in reading between the figures, and I hope thereby to find and point out a lesson that may be useful, and one that has an important bearing on the subject at issue. Possibly in doing so I shall interfere with the logic of your correspondent, but that I cannot help; in fact, my object, which I will not attempt to disguise, is to weaken the case of "J. B. K." and to strengthen my own. It is just a case of practice against science—a plain worker against an accomplished rhetorician and skilled theorist. I do not find the slightest fault with the way in which "J. B. K." has discussed my letter, and I feel sure he will not demur to my mode of dissecting his. It has been said, and I think truly, that when science and practice clash that either the one or the other is wrong—the science is not true, indeed is not science at all, or the practice is not sound. I will now endeavour to prove that my practice of applying guano, &c., to garden crops as detailed on page 476 is not unsound. I cannot do this by figures, but I can by evidence, which is equally powerful—results, facts.

But in the first place I must refer to the figures of "J. B. K." and see what is in them, and especially what is between them. Guano is first mentioned by your correspondent, and it will suffice that I refer exclusively to that manure. I will not question the accuracy of the figures but will take them as they stand. According to my showing and which was fairly admitted by "J. B. K." my mode of applying guano to rows of Peas and Scarlet Runners in trenches—namely, pouring a gallon of water holding in solution about 1½ oz. of guano to a square foot of soil, is reduced to just half that quantity of manure, as I particularly explained when a soaking of pure water was given just previously, which is the right mode of applying liquid manure in dry weather. Now the cost per acre at that rate of application according to the reckoning of "J. B. K." is £120. Now for the "between," for it is there that "J. B. K." is at fault—seriously at fault—and where his science must, I think, fall before my practice. I assert, and will prove my position to demonstration, that the amount there given is at the least five times too large, for the simple reason that the rows of Peas were 5 feet, and the rows of Beans more than 6 feet apart, and not a particle of manure was used between the rows. I must ask "J. B. K." therefore, to deduct the quantity and amount from the space between the rows—more than four-fifths of the acre, and further ask him if he seriously believes that the amount actually given "poisoned the crops?" I will not, however, permit a matter so important to rest on the mere opinion or belief of anyone, but will answer the question myself, and I desire my reply to be firm and emphatic. It did not poison the crops, it did not injure them, but it benefited them.

In point of fact it could not do otherwise than benefit such crops during such a season as the one referred to, and I further assert that the fertilisers were used profitably—hence economically. The great advantage in applying support in that form is that it goes direct to the object. It is not wasted between the crops by making the weeds (where there are any) more luxuriant, but is appropriated by the crops which require assistance and which give a profitable return on the outlay invested.

Let me here remark that the homœopathic mode of applying fertilisers is during some seasons—perhaps during most, and under a majority of conditions—not only not economical but often wasteful. I have recently read an account of an artillery duel between two opposing batteries. The shots from one battery all fell short. The powder was no doubt the best of its kind, but there was not enough of it; it was wasted. It is precisely the same with fertilisers. They may be of the best, but if they are not applied in sufficient quantities and in obedience to the dictates of the state of the crops and the requirements of the owner of them, taking into account also the character of the season and the nature of the soil, they are wasted, and what was considered as economy really becomes extravagance. In such a season as the one referred to guano is wasted when merely sprinkled on the surface of the soil "once a-year at the rate of 3 cwt. per acre." I can adduce actual proof of that—namely, that 3 cwt. per acre applied once a-year is extravagance, while frequent applications of the quantities I recommended are profitable. That statement appears paradoxical, but I have proved the truth of it by results. I have had something "to do" with a farm. During the year referred to the orthodox quantities of fertilisers were applied to the farm adjoining the garden where I was engaged; but the farm produce was miserable—a failure and loss, great loss was incurred, yet the garden crops were full, good, and profitable. By want of food lambs died by scores, and the shepherd sent every morning to the garden for such green food as he could be supplied with to prevent further loss by the barrenness of the farm.

But the question is one of gardening, not of farming, and I should not have brought forward that experience had not "J. B. K." advocated farm quantities. I say that farm quantities are totally inadequate for garden purposes. The quantities I recommended on page 476 are for garden crops. I have proved that they are safe quantities, and, when applied as there stated, profitable. The quantities are safe, but the frequency of their application depends on circumstances—on the condition of the crops and the weather. During the year referred to the crops were soaked no doubt about "eight times," and I am sure not one too many. In a season like the present one or two applications would suffice to enable the crops to be luxuriant—full—profitable.

Farm quantities of fertilisers as applied to garden crops are starvation quantities, and would drive a market gardener into the Bankruptcy Court. The amount of manure annually used in the market gardens of London is five times as great as is ordinarily used on farms. Would those thrifty, industrious, and I may justly add splendid cultivators expend such immense sums in purchasing manure as they do if it were not profitable? It is obvious that they neither would nor could do so. It is half manuring and half watering that are really extravagant; adequate manuring and adequate watering which are lucrative, and therefore economical. The quantities of water and manure that I have recommended are every year appropriated by the crops in the London market grounds.

It may be well to pause for a moment and ask, What is a good farm crop and what a good garden crop? I do not know that the former can be put more fairly than by stating that the produce of two acres of average land is required for three years to grow and fatten a good bullock, which is then worth about £30. Now, let us take a typical garden crop—Onions. Mr. Aberhant of Mitcham has grown 16 tons of Onions on an acre of ground, and sold them for £12 per ton—£192 per acre; and last year Mr. Bishop, Bylaugh, East Dereham, produced a crop which averaged 30 stones per square rod, or about 30 tons to the acre. This extraordinary crop was produced by the aid of liquid manure, principally stable urine, and much stronger than any applications which I have recommended, and which "J. B. K." alludes to as wasteful. But I do not consider that Mr. Bishop wasted the liquid manure when he produced a crop of Onions worth, at £12 per ton, nearly £400 per acre. These weights and values are not arrived at by any mere rules of logic, but are crops which have been actually produced. They prove also the great difference between farm and garden culture, and how utterly inadequate are the quantities of fertilisers recommended by your correspondent for the full and lucrative production of garden crops.

"J. B. K." has also stated that the quantity of water that I named as having been given during the tropical summer of 1868 was excessive. His position on this point is admittedly theoretical, and is, I submit, fallacious. Your correspondent takes the rainfall as his base, and says that as the average

rainfall of a very moist summer is about 4 inches a month, therefore I gave twice as much water as the crops required. I had two very powerful reasons for not giving more than was required—namely, the difficulty of procuring water and the lack of time for using it. If my twenty-five years of experience as a gardener has taught me anything—experience which I think the Editors know has not been without some fruits—it is this, that the crops did not receive a drop too much.

Opinions deduced from rainfall are not always sound, and they never can be sound unless something besides the mere rainfall is considered. The rainfall in the hill district of Cumberland is of more than twice the weight of the rainfall in the fens of Lincolnshire and the flats of Cambridgeshire, but the influence of the water on the soil and crops is about the same in both cases. No one can say that Cumberland has twice the quantity of rain that is necessary for the district, or that the fen country on the east coast has only half sufficient. The fact is that during most seasons it is more than the crops require, notwithstanding the little that is caught in the gauges.

The rainfall taken alone is no test as to the real dryness or wetness of a district, nor is the amount falling on a "rainy day" a sufficient guide for applying water artificially during a period of tropical weather. A dull rainy day when only an inch of rain falls has more power in supporting the crops than has water representing in amount 3 inches of rain when the element is applied artificially during a period in summer when the days are cloudless and the nights dewless. It is not the actual water that falls from the clouds that must be the sole guide in determining the requisite artificial supply, for there is another all-important factor in the sum (measureless it may be, but is yet immense)—evaporation—which must be taken into account, and without which any conclusions arrived at will and must be erroneous. "J. B. K." appears to have overlooked the question of evaporation as he had forgotten the ground between the crops. I adhere to all I have previously written on fertilisers and their application.—A RETIRED GARDENER.

ROSES IN SOUTH WALES.

MUCH, but not a line too much, is written about Roses in England, but reference is rarely made to Roses in Wales, hence an allusion to them may be acceptable.

Some varieties of Roses commenced blooming here about the second week in June, but the earliest buds do not as a rule produce the finest blooms, as they are often injured by the cold winds in April. The best flowers follow the buds formed in May and the early part of June, and consequently ours were about at their best during the "Rose week"—the time of the National Show. The season has been favourable to a certain extent for Roses in this part of Wales—a mild spring, plenty of rain, and a good deal of heat, only too frequently overbalanced by cutting east winds. The winters here are comparatively mild and the summers hot. The soil in every part would not grow Roses well, but abundance of excellent loam can be had to form beds, and the situation is well sheltered from the north about two miles off, and partially protected from the sea, but is much exposed to the east, from whence much damage is done in spring.

There is more in having a good situation for Rose-growing than good soil. Deficiency in the latter can always be made up by manure, but it is no easy matter to have good Roses in a bad season without shelter. Some say that late pruning will induce late blooming. This may be so, but early pruning will not cause the plants to bloom early. Some Roses were pruned here in November last, and others in March and April, but they all bloomed together just as if they had been pruned on the same day.

Referring to our best varieties and those which seem to succeed best in this part, Duchess of Edinburgh has come out well, and so has the Duke of Edinburgh, which is much superior in form and colour to the first-named. By far the best dark Rose we have is Louis Van Houtte. It has not grown very strongly, nor the blooms are not large, but the depth of claret shade in them is superb. La France, in a position where it only gets an hour or two's sun in the afternoon, has grown well and opened some good blooms, and they remain much longer perfect than when fully exposed to the sun all day. Hippolyte Flandrin is somewhat after the same colour, but more globular in form and a freer bloomer. The old Général Jacqueminot still shows up well amongst the others, and this, with Charles Lefebvre and John Hopper, are three Roses which would, I think, succeed anywhere. Baronne de Rothschild

bears the same character and is doing well here. Sénateur Vaisse has some splendid blooms. Thomas Mills and Thomas Methven have not succeeded. The first is weak in growth; the latter has grown well enough and shown plenty of buds, but not one of them has opened. Prince Camille de Rohan, a fine Rose in some districts, is not so with us; and Princess Antoinette Strozio is poor; but Marquise de Gibot and Marquise de Mortemart are both splendid, the latter especially, although it is said to be delicate in many places. François Michelson does as well here as it need be desired anywhere. Centifolia Rosea has plenty of wood and leaves, but is deficient in flowers. Edouard Morren is splendid, its massive pink blooms not being surpassed in size or substance by any other sort. Without enumerating more varieties I may state that, with the few exceptions which occur in all gardens, Roses will do equally as well in South Wales as in any part of England, and the only thing to be regretted is that they are not grown more extensively than they are.

There is only one really good amateur's collection in the neighbourhood, and that belongs to Mr. Powell, Eglwyswmyd, who has a garden that shows there are exceptions to all rules when it is asserted that farmers' gardens are invariably characterised by bad management. All our Roses are on the Briar and Manetti stocks, and so are a good many of Mr. Powell's, but this season he is trying some on Mr. Prince's seedling Briars, and so far they have done well.

Amongst the Hybrid Perpetual varieties of more than ordinary merit in the Eglwyswmyd collection I may name L'Esperance, Fisher Holmes, Horace Vernet, both magnificent darks; Dupuy-Jamin, Duc de Wellington, Countess of Oxford, Boule de Neige, Abel Grand, Baronne Prevost, Sir Garnet Wolseley, Dr. Andry, Jean Cherpin, Madame Victor Verdier, Pierre Notting, May Turner, and Monsieur Claude Levet. Tea-scented—Cheshunt Hybrid, Alba Rosea, Clotilde, Homère, Madame Falcot, Safrano, Marie Van Houtte, Souvenir de Paul Neron, Madame Margottin, and Perle de Lyon. These Teas are chiefly growing in a border against the house, and if they are more tender or worse to cultivate than the Hybrid Perpetuals they have not yet shown signs of it here.—J. MUIR, Glamorganshire.

CARNATIONS AND PICOTEEES.

PHILLIPS has written the history of these flowers, and we have little to add to his notes. Chaucer says that the Clove Gillyflower was cultivated in this country as early as the reign of Edward III., and that it was used to give a spicy flavour to ale and wine, and from hence it was called Sop-in-wine:—

"Ther springen herbes grete and smale,
The Licoris and the Setewale,
And many a Clove Gilofre,
——— to put in ale,
Whether it be moist or stalle."—Chaucer.

It seems to have been a flower in high estimation in Queen Elizabeth's time, since we find it so often celebrated by the poets of her day. Spenser, who was remarked for his care in retaining the old manner of spelling, calls them Coronations, probably because they were used on these festive occasions, and from hence the name of Carnation seems a corruption. Some writers are of opinion that they were called Carnations after a flesh colour so distinguished, whilst others suppose that the colour was so named from the tint of the Carnation flower.

"Carnation'd like a sleeping infant's cheek."—Lord Byron.

Spenser says in his "Shepherd's Calendar":—

"Bring hether the Pincke and Purple Cullambiae,
With Gelliflowres;
Bring Coronations, and Sops-in-wine,
Worn of paramours."

The name of Clove, as well as that of Caryophyllus, was given to this species of Dianthus from the perfume being similar to that of the spice so called, and the flower was on that account frequently used to flavour dainty dishes as well as liquors, and it was also thought to possess medicinal properties. Gerarde tells us that he had a Carnation with yellow flowers, "The which," he says, "a worshipfull marchant of London, Master Nicholas Lefe, procured from Poland, and gaue me therof for my garden, which before that time was neuer seene nor heard of in these countries."

He enumerates by name forty-nine kinds of Carnations that were cultivated in the time of Charles I., whose Queen was excessively fond of flowers; but although it appears that varieties were then procured from France and other parts of

the Continent," yet the largest and principal kind of Carnation was then distinguished by the name of the Old English Carnation.

During the civil commotions of the latter part of the reign of Charles I. and of the Commonwealth, this flower seems to have been nearly lost in England, as Mr. John Rea remarks in the "Flora" which he published in 1665, that we had formerly many good kinds, but that few of them were then to be found in any of our gardens. The Dutch had then taken up the cultivation of the Carnation, and we renewed our gardens with these flowers from Holland during the reign of Charles II., as Rea observes:—"Of these Dutch flowers I have known more than a hundred distinct varieties by several names, all of them fair, large, and double flowers." He also remarks that these plants were not so hardy as those that had been formerly cultivated in England. In a later edition of Mr. Rea's "Flora" 360 good sorts of Carnations are enumerated; and to show how high this flower was in the estimation of that author, we give his own words:—

"For various colours Talips most excel,
And some Avemonies do please as well,
Bannunculus in richest scarlets shine,
And Bear's Ears may with these in beaute joyn;
But yet if ask and have were in my power,
Next to the Rose give me the Gillyflower."

Modern florists divide these flowers into three classes—Flakes, Bizarres, and Picotees. The Flakes are so called from

Fig. 16.—The Carnation.

having two colours only, and their flaky stripes going quite through the petals. Bizarres are so named from the French word, which signifies odd or fantastical. These kinds have not less than three colours, and are variegated in irregular stripes or spots. Picotee is a corruption of the French, *piquetée*, pricked or spotted. These flowers are distinguished by having a clear ground, pounced or spotted with purple, rose, red, or other colours. These classes are again subdivided, as Pink Flakes, Scarlet Flakes, Purple Flakes, Yellow Flakes, &c., and the Picotees and Bizarres run through the same changes almost to an endless amount.

It is gratifying to observe that a flower so old and honoured as the Carnation—the "Coronation flower"—a fit flower for a diadem—is honoured still. "Next to the Rose," said old Rea, "give me the Gillyflower" (Carnation), and more than two hundred years later we say the same, for like the Rose it is hardy, beautiful, and sweet. Wherever the Rose will flourish there also will the Carnation prosper. Let them dwell together in sweet companionship. But while the Carnation will succeed

where the Rose thrives, the Rose will not always flourish where the Carnation grows and flowers in healthy freedom. The Rose, although otherwise so hardy, speedily succumbs to a polluted atmosphere; the pure breath of nature is indispensable for its well-being. But the Carnation is a flower of and for the town as well as the country. A murky atmosphere cannot prevent its beauty unfolding or its perfume penetrating the smoke-laden air. It is the flower of flowers for town gardens—the little home plots which skirt our cities, and we would like to see it in all of them—a hardy garden flower. We know of some Carnations now in a little London garden which are viewed with envious eyes (is not such envy pardonable?) by the passing crowd.

As an exhibition flower the Carnation is equally worthy of patronage. It is the cultivating and exhibiting of beautiful flowers—florist flowers—which increases their popularity. Had it not been for a previous exhibition of the National Carnation Society the flowers referred to in the little London garden would not have been there. We know, too, of another town garden where some of the varieties which charmed the visitors at South Kensington last year are now growing and blooming. Perhaps these small collections are owned by exhibitors in embryo. Who knows? But at any rate the flowers are doing good, for they are imparting pleasure, and brightness, and sweetness where such influences are required and where they are appreciated. These are only two instances of the power

Fig. 17.—The Picotee.

of exhibitions in promoting the cultivation of flowers. Can they be the only two? We think not; but, on the contrary, we think and we hope there are many more. We wish, therefore, to see exhibitions of florist flowers increase and expand, because their direct tendency is to increase the love for flowers. All who are engaged in such a work are engaged worthily, for we consider the object to be of great public advantage, and our hope is that the exhibition of Carnations and Picotees now on the eve of being arranged will be very successful.

It was recently stated by a correspondent that the season of blooming and the time of increasing the Rose occurring together contributed materially to increase the cultivation of that flower. The Carnation possesses the same advantage. It is during the period of flowering that layering must be effected and pipings inserted. A good old florist has given the following directions on propagation. If any modern florists can describe better modes we shall be glad to record them:—

"**LAYERING.**—The plant should be placed in the sun, so that it may become dry and pliable before the layers are bent

down, as when they are too full of moisture the branches frequently snap off at the joints. The layers are prepared by cutting off their lower leaves, and an incision is made by entering a quarter of an inch below the joint, and passing the knife up through the centre of it. It is then placed on the earth, which should be first stirred up, and after it is properly pegged down the branch should be covered with a good light but rich earth, about half an inch in depth.

"PIPIINGS.—Where shoots are too short for layering, or where they become broken by accident, it is necessary to have recourse to piping, and for this purpose it is necessary to have a slight hotbed, and cover it 4 or 5 inches deep with fine light soil, laid very regular and even. The cuttings intended to be piped are to have two complete joints—that is to say, they are to be cut off horizontally close under the second joint. The pipings are then to be firmly inserted in the soil, but not more than half an inch deep; they are to be very gently watered, in order that the earth may adhere more closely to them, and thereby keep out the air. After this watering they are to remain open, but not exposed to a hot sun, till their leaves become perfectly dry, after which the glass is to be placed over the same mark that was made by it upon the surface of the soil. The soil should be kept regularly moist till they have formed their fibres; but too much moisture is as prejudicial as too little. The pipings should have a little of the morning sun, but must be shaded from it when the heat becomes considerable."

The characteristics of a Carnation are, says one of our contributors, best seen by the figure, which is, however, not more than half the size to which modern floricultural skill has brought this flower. The pod (as the calyx is technically called) should be long, as then the flower is not liable to burst it, as is the case when it is short. The flower should be quite circular, and rising up gradually towards the centre, so as to form half a ball. The outer or guard petals should be large and few in number, and the other petals should be regularly disposed on them, and diminish in size towards the centre. In saying this he begs it to be borne distinctly in mind that such a flower as is represented in the drawing is what is called a dressed flower. The texture of the petals should be thick and waxlike, and the markings distinct and clear; the ground a pure white, any flushing or running of the colour being a decided disqualification.

In the case of the Picootee the same rules hold good in reference to shape and substance; while the colour should be confined to the edge, and not run down the petals in bars.

ROYAL HORTICULTURAL SOCIETY.

JULY 17TH.

For several months past the meetings, which have often been exhibitions of considerable magnitude, have been held in the conservatory, but on this occasion the Council-room was occupied by the Committees and exhibits, and it must be added was occupied well. The tables surrounding the room were quite filled with Vines in pots, flowering and fine-foliaged plants, cut flowers such as Roses, Fancies, Pelargoniums, &c., several dishes of fruit, and good examples of vegetables. There was also a good attendance of horticulturists.

FRUIT COMMITTEE.—John Lee, Esq., in the chair. Messrs. Lane & Son of Berkhamstead sent six Vines in pots of extraordinary growth, which were considered by the Committee to be the finest that had ever been exhibited at any meeting of the Society. The Committee recommend them for the award of a silver medal. There were four Black Hamburgs and two Foster's Seedlings. Some of the bunches on the former would exceed 3 lbs. in weight, and on one of the latter we counted twenty bunches averaging a pound each. Mr. Ollerhead, gardener to Sir Henry Peek, Wimbledon House, sent a well-grown Queen Pine weighing 4 lbs. 12 ozs., to which a letter of thanks was awarded. Mr. Miles of Wycombe Abbey exhibited a remarkably fine dish of Bigarreau Napoleon Cherry, to which a cultural commendation was awarded. Mr. Burnett, The Deepdene, Dorking, sent two fine dishes of Peaches and one of Nectarines, which received a cultural commendation. Mr. W. Bull, King's Road, Chelsea, sent a brace of Cucumber Excelsior, fruit of which was exhibited at the last meeting. It is a handsome Cucumber of the old-fashioned White-spine class, to which a letter of thanks was awarded. Mr. J. Geary, Moreton Gardens near Bideford, sent a seedling Cucumber which was not an improvement on other varieties in cultivation. Mr. Charles Turner, Slough, sent a dish of Schoolmaster Potato and Dandie Dimont Peas, and as both of these are growing at Chiswick the decision of the Committee was reserved for a meeting at the garden. Mr. I. Collett, gardener to W. J. J.

Higgins, Esq., Hambledon, Hants, sent a dish of Peas, which is no improvement on ordinary Peas. Messrs. Carter & Co. sent plants of a fine-looking Pea named Little Wonder, of which they entertained a high opinion, and recommended that it be tried at the garden. Mr. H. J. Hardy, Bures, Essex, sent plants of a new Pea called Sequel, and it was recommended to try it at Chiswick.

FLORAL COMMITTEE.—W. B. Kellock, Esq., in the chair. Messrs. James Veitch & Sons, Chelsea, exhibited a collection of extremely fine tuberous Begonias. First-class certificates were awarded to Monarch—a real monarch in its class—of robust stately habit, and with fine vermillion flowers; also to Charles Scorer, the finest and richest of all the varieties yet raised. This variety possesses a combination of good qualities—namely, dwarf habit, great freedom of flowering, good-shaped flowers, and colour of such a rich velvety crimson scarlet as is seldom seen in any flower. B. Davisii, a dwarf species, in this group was clear, bright, and dazzling; and B. roseiflora, another dwarf species, was very distinct and pleasing. The collection also included the double varieties Gloire de Nancy and Lemoinei. Messrs. Veitch also exhibited dwarf examples of the valuable conservatory decorative plant *Lisianthus Russellianus*; its fine, purple, Tulip shaped flowers were highly effective. The same firm also exhibited the new white *Hydrangea* Thomas Hogg, and owing to its distinctness, also, we presume, to its good keeping property, a first-class certificate was awarded. A few other plants were also exhibited by the same firm.

Mr. Pithers, The Gardens, Munster House, Fulham, also exhibited some seedling tuberous Begonias, one of which, *Illuminator*, was extremely brilliant and had fine flowers, but the plant was somewhat drawn and shaken. This class of Begonias especially, were they are not grown in too much heat, are invaluable for summer decoration.

Mr. B. S. Williams, Holloway, exhibited a small group of plants. *Croton* Queen Victoria was in splendid condition and was awarded a first-class certificate; it must rank as one of the finest of the genus. *C. fasciatus* had very large Magnolia-like foliage clearly veined with yellow. *Lobelia Lilac* Queen, a variety of the *Pumila* section, is a charming decorative plant, distinct in colour, close in habit, and pleasing. *Adiantum palmatum* and *Woodwardia radicans cristata*, two distinct Ferns, were included in this group.

Lælia Brysiana, with four spikes and seventeen grand flowers, was exhibited by Mr. Spyers, Orchid grower to Sir Trevor Laurence, Bart., M.P., Burford Lodge, Dorking, and for which a cultural certificate was awarded; also a fine plant of the remarkable *Brassavola Digbyana*, for which a medal was recommended; and the equally singular *Dendrobium Jerdenianum*. Mr. Selwood, gardener to the Duke of Westminster, Eaton Hall, exhibited a fine plant, like a fountain of gold, of *Dendrobium filiforme*. This plant was growing in a basket, and was a fine example of superior cultivation. A medal was recommended to be awarded to Mr. Selwood.

Mr. Mill, gardener to Lord Rendlesham, Rendlesham Hall, Suffolk, was awarded a first-class certificate for *Odontoglossum miniatum*, a splendid *Odontoglossum*, resembling in colour a fine variety of *Oncidium crispum*. The spike had eighteen fine flowers, and was much admired.

G. F. Wilson, Esq., F.R.S., exhibited cut blooms of *Lilium* eximium, *Robinsoni*, *Pardalinum*, *Kramerii*, *Martagon album*, &c., all very beautiful; also flowering spray of the hardy *Tropeolum speciosum*, which is so brilliant in Scotland, but which Mr. Wilson has proved will flourish in England if a cool place is selected for the plant. A vote of thanks was awarded. Messrs. Barr & Sugden, Covent Garden, staged a very gay collection of *Lilium* in about thirty sorts; also richly-coloured Irises, including *I. Kæmpferi* General Grant. H. J. Elwes, Esq., Preston, Cirencester, exhibited a very richly-coloured variety of *Lilium elegans*; also a spike of *Pentstemon Cobæa*, a pale purple species from Texas, which is seldom seen, and a vote of thanks was awarded.

Mr. Woodbridge, gardener to the Duke of Northumberland, Syon House, sent flowering sprays of *Stewartia* (*Stewartia*) virginica, a beautiful North American shrub with large white flowers resembling those of Clematises, and foliage very like that of *Syringa*; also *Cerasus ilicifolia*, and received a vote of thanks.

Messrs. William Paul & Son exhibited a collection of Roses raised at or first introduced to commerce from the Waltham Cross Nurseries—the finest collection of the kind that we have seen staged. Twenty of the varieties were named and six numbered. Amongst the former *May Quennell* was pre-eminent. It has the same stout petals as *Star of Waltham*, but is far superior to that good Rose, and indeed to all others of its colour—crimson suffused with magenta. It was certificated at a previous meeting. Some other Roses in this collection will be heard of again. The colour of one approaches to violet. Mr. Turner exhibited *Penelope Mayo*, a fine Rose of the *Marie Baumann* type; also a white Clove Carnation *Mrs. Matthews*,

pure, smooth, sweet, and altogether good, and for which a first-class certificate was awarded. Mr. Noble exhibited his new Rose Queen of Bedders, one truss of which was composed of twenty buds.

Mr. J. Croucher, gardener to J. Peacock, Esq., Sudbury House, Hammersmith, exhibited *Echinocactus grandicornis*, globular-shaped and about 8 inches in diameter, boldly ribbed and covered with extraordinary hooked spines 4 inches in length. A first-class certificate was awarded; and Messrs. Croucher & Boller, 73, South Row, Kensal New Town, staged several examples of the Old Man Cactus (*Piloceris senilis*), and received a vote of thanks.

Mr. Parker, Tooting, received a first-class certificate for *Lathyrus latifolius splendens*, a fine hardy perennial Pea with purplish-crimson flowers. Mr. Parker also exhibited blooms of the York and Lancaster Rose, and some *Liliums*. Mr. John Reeves, nurseryman, Acton, exhibited a collection of Balsams of an excellent strain. The plants were extremely sturdy and well flowered, and the flowers were large, perfectly double, and in distinct colours. The strain was highly commended, and a vote of thanks was accorded. Mr. James Pattick, florist, Acton, staged about a hundred "market plants"—well-grown examples of *Lycopodiums*, *Fuchsias*, *Kalosanthes*, and other plants in season, and received a similar award. The thanks of the Committee were also awarded to Mr. Cannell for collections of cut flowers of fine varieties of double and single *Geraniums*; also a plant of a variety correctly named Half-and-Half, half of the pips being rosy crimson and the other pale salmon; also for a *Geranium* half Zonal and half Ivy-leaf, and for cut blooms of *Mimulus* and Sweet Williams. A similar mark of recognition was made to Messrs. Downie & Laird, Edinburgh, for a collection of Pansies.

NATIONAL CARNATION AND PICOTEE SOCIETY'S SOUTHERN SHOW.

ROYAL AQUARIUM, JULY 18TH.

A WELL-ARRANGED schedule, numerous and liberal prizes, a tolerably fortunate date for holding the Show, a place where it could be seen to advantage, also a fine day, combined to render this field day of southern florists, or rather of florists in the south, a successful one. Possibly if the season had not been so late more blooms would have been staged, but they could scarcely have been finer. The finest flowers in the Show—those from Mr. Douglas and Mr. Turner—had been advanced under glass. Splendid blooms were staged by both those growers, and it is no small honour to Mr. Douglas that he was placed equal first with Mr. Turner in the class for twenty-four Carnations, while he fairly beat the great Slough champion in the corresponding class for Picotees.

The claims of florists' flowers to special patronage are great; their intrinsic beauty will always command admirers and able and ardent cultivators; but for some time past flowers for massing—flowers of brilliant hues, of rapid increase, easy culture, and quick display have been fashionable, while those of slower growth and requiring closer attention and greater skill to bring them to perfection, have suffered a certain and too great amount of neglect. Roses it is true have not been neglected, but much of their popularity—that is, the popularity of blooms of high quality, is due to the special efforts which have been made by the specialists, now known as rosarians. The Carnation, next to the Rose, ought to be the most popular of English garden flowers. It possesses the same attractive qualities as the Rose, while it is even more lasting in its beauty than the queen of flowers, as will be doubtless proved by the condition of the blooms during the second day of this real English Show of real British flowers. It is gratifying, therefore, that a few friends of the Carnation are still left in the south, and none having a real love for the flowers which they cherish can do otherwise than rejoice to find success attending what must be a work of considerable labour—pleasant labour, nor cease to hope that the efforts now made will give a stimulus to other cultivators, and result in adding new recruits to the florists' ranks, and to a Society whose object is so laudable as the Society which is in session to-day.

For once the Carnation has priority over the Rose—the Roses exhibited being a supplementary branch, and not an inappropriate one—a powerful ally, but only an ally, of a show of the Carnation. It was an opportunity for Roses being brought to Westminster, where surely they must be welcome—for one day at least; and for the sake of that one day of enjoyment to many, the few who can only view a faded or imperfect Rose with feelings of pain, must endure whatever share of disappointment falls to the lot of those who are "martyrs to circumstances."

But we must refer to the Show. We pronounce it without any reservation good—such a show of these hardy garden flowers that has certainly not been seen in Westminster before, if anywhere else; and the promoters of both sections of the Show—Mr. Dodwell of the Carnation department as the zealous Hon. Sec. of the National Society, and Mr. Bennett of the Rose department, the Aquarium Company's Floral Manager—are to be congratulated on the arrangements and results.

The boxes were arranged on two tables, and the plants in pots from Mr. Turner and Mr. Douglas added greatly to the effect of the Show. They were in 7-inch pots, each plant carrying six to twelve exhibition blooms.

CARNATIONS AND PICOTEEES.

CARNATIONS.—Four classes were provided, and forty-four prizes.

Class A, twenty-four blooms in not less than twelve varieties, brought out five competitors. The prizes were 70s., 50s., 30s., and 20s., and the winners of them were—first, Mr. Turner, Slough, and Mr. Douglas, gardener to F. Whitbourn, Esq., Loxford Hall, equal; second, Mr. E. S. Dodwell; third, Mr. T. S. Ware, Tottenham; fourth, Mr. Hooper, Bath. Mr. Turner staged Sybil (Holmes), Eccentric Jack (Wood), James Douglas (Simonite), Mary Ann (Fletcher), Ajax (Hextall), Duke of Edinburgh (Abercrombie), Merrimac (Woods), John Bailey (Dodwell), John Keet (Whitehead), Florence Nightingale (Sealey), Sportsman (Hedderly), Flora's Garland (Holmes), Mr. Hextall (Simonite), Squire Trow (Jackson), Annihilator (Jackson), and Admiral Curzon (Eason). Mr. Douglas had James Douglas, Admiral Curzon, Lovely Ann, J. D. Hextall, Rose of Stapleford, Mr. Battersby, Samuel Newman, Rifleman, Premier, Dreadnought, Falconbridge, True Briton, John Keet, Earl of Stamford, Mars, Sarah Payne, John Bailey, Juno, James Taylor, Lord Raglan, The Clipper, and Marshal Ney.

In Class B, for twelve blooms, the six prizes offered were awarded as follows:—First, Mr. Douglas; second, Mr. Dodwell; third, Mr. John Hines, Ipswich; fourth, Mr. S. Bertram, Woodbridge; fifth, Mr. J. Buxton, 32, Wandsworth Road, London; sixth, Mr. Catley, Bath. Mr. Douglas staged grand blooms of John Keet, Marshal Ney, Admiral Curzon, James Douglas, True Briton, J. D. Hextall, The Clipper, Rifleman, Sportsman, Mary Ann, Satisfaction, and Premier. Mr. Dodwell's blooms were rather smaller, but most of them were highly finished, especially James Merryweather, True Briton, John Keet, Sportsman, and Mrs. Dodwell, rose flake, very beautiful.

In Class C for six blooms there were four competitors, the awards being made in the following order:—First Mr. A. Medhurst, 32, Priory Road, Wandsworth Road; second Mr. Ellis, Wandsworth Road; third Dr. Abercrombie, Cheltenham. The first-prize collection consisted of James Douglas, John Bailey, Admiral Curzon, Mars, John Keet, J. D. Hextall.

Class D, single specimens. In *Scarlet Bizarres* Mr. Douglas was first, second, and fifth with Admiral Curzon, and third with Companion; and Mr. Hines was fourth with Lord Randolph. *Crimson Bizarres*.—Mr. Turner was first with Unexpected, and second with Mr. Hextall; Mr. Douglas being third, fourth, and fifth with Marshal Ney, John Hextall, and Graceless Tom respectively. *Pink and Purple Bizarres*.—Mr. Turner was placed first, second, and fourth with James Taylor, and third and fifth with Sarah Payne. *Purple Flake*.—Mr. Turner was first with True Blue, second and fourth with James Douglas; Mr. Hines third with Mayor of Nottingham, and Mr. Turner fifth with Ascendant. *Scarlet Flake*.—Mr. Turner was first with Sportsman and fourth and fifth with Annihilator, and Mr. Douglas was second and third with Sportsman. *Rose Flake*.—Mr. Turner was first and third with Sybil, Mr. Hine was second with the same variety, and Mr. Turner was fourth with Mary Ann and fifth with John Keet.

Premier Carnation selected from the whole Exhibition.—This proud honour was won by Mr. C. Turner with Sybil.

PICOTEEES.—The number of prizes and the amounts offered were the same as in the Carnation classes.

Class E, for twenty-four blooms, brought out five competitors, and the prizes were awarded as follows:—first Mr. Douglas, second Mr. C. Turner, third Mr. Dodwell, and fourth Mr. Ware.

Mr. Douglas's collection contained splendid blooms of Mr. Price, Obadiah, Mrs. Bower, Mrs. Allcroft, Mary, John Smith, Edith Dombrain, Prima Donna, Princess of Wales, Ann Lord, Miss Small, Mrs. May, Mrs. Little, Lord Valentia, Ethel, Gany-mede, Picco, Juliana.

In Class F, twelve blooms, there were seven competitors, with the following result:—Mr. Douglas was first again with grand blooms; second Mr. Dodwell; third Mr. Buxton; fourth Mr. Bertram, Woodbridge; fifth Dr. Abercrombie; sixth Mr. Hines.

In Class G, for six blooms, the following exhibitors were successful:—First Mr. Medhurst; second Mr. Ellis; third Mr. Gibson, gardener to T. F. Burnaby Atkins, Esq., Sevenoaks. The first-prize collection consisted of Leonora, Mrs. Niven, Alice, Juliana, Clara, and J. B. Briant.

Single Specimens.—*Red Heavy-edged*.—Mr. Bertram was first with Col. Clarke; Mr. Douglas second with Princess of Wales; Mr. Turner third and Mr. Hines fourth with Princess of Wales; and Mr. Turner fifth with Rev. F. D. Horner. *Red Light-edged*.—Mr. E. S. Dodwell was the only exhibitor, and had the first prize with Thomas William. *Purple Heavy-edged*.—Mr. Turner was first with Leah; Mr. Douglas second and fifth with Chanticleer, and third with Mrs. May; Mr. Turner being fourth with Cynthia. *Purple Light-edged*.—Mr. Douglas was first and third with Mary; Mr. Turner was second with Cynthia, fourth with

Harland, and fifth with Alice. *Rose or Scarlet Heavy-edged*.—Mr. Turner was first with Lady Louisa, second with Leonidas, fourth with Venus, and fifth with Gem of Roses; and Mr. Hooper was fourth with Princess Alice. *Rose or Scarlet Light-edged*.—Mr. Douglas was first with Mrs. Allcroft, second with Ethel; and Mr. Turner was third, fourth, and fifth with Miss Wood, Mrs. Allcroft, and Miss Wood respectively.

Premier Picotee selected from the whole Exhibition. This high prize was won by Mr. Douglas with John Smith.

Yellow-ground Picotees, twelve blooms in not less than six varieties, the prizes went in the following order—first, Mr. T. S. Ware, Tottenham; second, Mr. Catley, Bath; third, Mr. Hooper, Bath. These were generally small and not particularly attractive.

Miscellaneous, *Sells or Fancies*.—In the class for twenty-four blooms in twelve varieties there were six competitors with the following result—first, Mr. C. Turner; second, Mr. Douglas; third, Mr. J. Buxton. Mr. Turner's blooms consisted of The Bride, Dr. Foster, Ambassador, James Merryweather, Flora's Garland, Lady Avenel, Albert, Golden Queen, Seedling, Sultan, Sybil, Elysian Beauty, Ajax, Unexpected, Mars, Cremorne, and Bridegroom. Twelve blooms *Sells or Fancies*—first, Mr. Turner; second, Mr. Dodwell; third, Mr. Cooper. Two others competed.

Plants in Pots.—"Twelve specimens, dissimilar (from any or all of the classes, including Tree Carnations), in pots not exceeding 8 inches in diameter." Mr. Turner and Mr. Douglas were awarded equal first prizes.

THE ROSE SHOW.

"A TWO-DAY Rose show and you at it! Fie, Fie, "WYLD SAVAGE." Where are your principles? Was it not you as much as anyone else—nay, were not you foremost at the National Meeting in repudiating such shows? And you to be at the Aquarium judging and showing, and then having the audacity to write about the Show, to publish your shame to the whole Rose world! I am ashamed of you, I blush for you."

Such I can well imagine may be the comments of some of your readers, particularly of one "LOVER OF CONSISTENCY," who in Journal and Chronicle has uttered his solemn warning and made us all tremble in our shoes. Well, I own it looks bad upon the face of it, but there are redeeming features about even this case. First, my proposal that we should pledge ourselves not to show at two-day exhibitions was opposed by all, and what we did was to resolve to do all in our power to discountenance these shows; secondly, this is not a regular Rose show, and at the meeting it was particularly objected by the great nurserymen to my proposal, that often Roses were affiliated to several horticultural or even agricultural exhibitions, and in my eagerness to pass my resolution I said, Of course excepting "mongrel exhibitions." So that even if we had pledged ourselves not to show we should be free from censure in this case, for it is the Show of the National Carnation and Picotee Society, and Roses are only added for the sake of variety, and to attract, I suppose, more visitors.

Then, next, if I am a sinner in this case I am not alone but in good company, for the question is, Who was not at the Aquarium? not who was. All the great nurserymen were there, and the leading amateurs, so do not be too hard on us dear Consistency, for we have very tender feelings, and it is the last show of the year, and our season is such a brief one, and there are (comparatively) so few shows, and we rosarians really cannot afford to lose an opportunity of meeting together at the court of our queen. What a beautiful place the Aquarium is for a Rose show. Here is space, light, no steps to drag our boxes up, civility, attention, a good place for the refreshment of the body and mind, a fine orchestra, and a hearty welcome. What more can we want? Perhaps the light on a very sunny day is a little too strong for our blooms, but we cannot have everything, and no doubt the authorities will some day put up an awning, when we shall have everything we want.

And now for the Show. What of it? I can imagine that in future years anyone who by chance came on my account of this Show might exclaim on seeing the date, "The 18th of July, and a Rose show in London! Surely it must have been a miserable failure, for what Roses would be worth anything so late as the 18th?" Well, it was not a failure, but very much the reverse, and the Roses were very fine, and the fixture was a remarkably good one, for a more exceptional season I for one never knew. When I remember that the first show of the year was at the Crystal Palace on Midsummer eve, and that the last was on the 18th of July, and that at each show Mr. George Paul and Mr. Turner showed, and showed finely, I am struck with amazement at the length of time their Roses held out. For nearly a month these great nurserymen have shown Roses, and shown them well too. And this is the more remarkable when we consider what scorching weather we have had in July. Mr. Cant was about a week behind his great rival, but when he was in bloom he was quite up to his old form. Mr. Cranston is always the latest of the quintet, but when his time does come how grand are his blooms! The Aquarium fixture just suited him, and

glad am I for one that this good fellow and fine rosarian should at last have one London show which was not too early for him. The distance that he lives from town must always handicap him; and when to this is added the exposed situation of his extensive nurseries, it is a marvel to me how he manages to show as well as he does at the metropolitan exhibitions. Mr. Keynes has also a very late soil and an exposed nursery, added to which his soil is one of the poorest that can be imagined, except where his standards and Dahlias are cultivated. In fact, his soil is as poor, or nearly so, as mine. The prizes at the Aquarium were exceedingly liberal when the number of blooms required for the various classes is taken into account, and I cannot too highly commend the Secretary or Manager who drew out the schedule for his liberality and discretion in making the classes easy for all growers. The leading class for the trade was for forty-eight varieties, and for this £5, £3, and £2 was offered. The head amateur classes were for twenty-four distinct and twelve trebles, and for these £4, £3, and £2 were given. Then there were classes for twelve Tea and six blooms of one Tea, and other miscellaneous classes. And now for the Roses, or rather for the prizes which were awarded for them, for time does not permit a comment on the several collections.

In the chief nurserymen's class, forty-eight varieties, single trusses, the prizes went in the following order:—First Messrs. Cranston & Co., Hereford; second Mr. Cant, Colchester; and third Messrs. G. Paul & Son, Cheshunt. In the next class—twenty-four varieties, trebles—Messrs. Cranston & Co. again had the premier place, followed by Mr. Turner, Slough, and Mr. Corp, Oxford. For twenty-four single trusses Mr. Corp was first, Messrs. Cranston & Co. second, and Mr. Bennett, Stapleford, third; and for twelve single trusses the prizes went to Messrs. Corp, Turner, and Bennett in the order named.

AMATEURS.—In the class for twenty-four Roses, distinct, single trusses, Mr. Jowitt, The Old Weir, Hereford, was placed first, Mr. Baker and Rev. E. N. Pochin equal second, and Mr. Davis, Wilton, third. For twelve trebles the awards went to Messrs. Baker, Camm, and Davis in the order named. In the class for eighteen singles Mr. Pochin was first, Mr. Jowitt second, and Mr. Davies, Aynhoe, Banbury, third; and for twelve blooms Mr. Pochin again had the first place, followed by Mr. Pemberton, Romford; Mr. Burnaby Atkins, Sevenoaks; and Mr. Whitwell, Darlington, in the order of their names.

OPEN CLASSES.—In the class for twelve Tea or Noisette Roses Mr. Cant was placed first, Mr. Corp second, and Mr. Davies, Aynhoe, third. For six blooms of any one sort of Tea or Noisette Mr. Tranter was first with *Maréchal Niel* in grand colour; Mr. Davies was second with almost equally good blooms of the same variety; and Mr. Keynes third with *Marie Van Houtte*. For six blooms of any one sort of Hybrid Perpetual Mr. Cant was first with splendid examples of *Alfred Colomb*, Messrs. G. Paul & Son second with *Duke of Edinburgh*, and Mr. Corp third with *Mlle. Marie Cointet*. The last class in the schedule was for six new Roses of 1875 or 1876. Mr. Turner, Slough, won easily with *Sir Garnet Wolseley*, J. S. Mill, very fine; *Maréchal Robert*, Prince Arthur, very fine; *Jean Liabaud*, and a splendid bloom of *Madame Prosper Langier*. Messrs. G. Paul & Son were second with Mrs. Baker, *Jean Liabaud*, *Royal Standard*, *Avocat Duivier*, and *Marguerite Brasseur*; and Mr. Corp third with fresh examples of *Duchesse de Valombrosa*, *Jean Souperet*, *Madame F. Janin*, *Jean Liabaud*, *Star of Waltham*, and *Abel Carrière*—all in excellent colour.

Many of the blooms exhibited bore unmistakeable signs of the lateness of the season and of having received rough usage by the late storms, yet many more were of undeniably good quality, and the colour of the darks and yellows was perhaps unusually rich; but more anon.—WYLD SAVAGE.

Seventy-two varieties of *Verbenas* from Mr. Turner, Slough, were highly effective, as were the plants of *Lilium auratum* from the same cultivator, which were placed down the centre of the tables. Mr. Cannell staged twenty-four varieties of *Verbenas*, and it is not too much to say that the collections of these flowers were as much admired as the Carnations and Roses. Mr. Turner also exhibited his fine new white *Clove Mrs. Matthews*, the blooms much resembling perfect *Gardenias*. Mr. Ware, Tottenham, staged a large collection of Carnations and *Pansies*; Mr. Hooper, Bath, also exhibiting *Pansies* well. Mr. Corp, Oxford, staged a large and charming collection of Tea Roses, and Mr. R. Dean submitted fine examples of *Mauve Queen Stocks*. The Vines in pots from Messrs. Lane & Son, Great Berkhamstead, attracted considerable attention.

The Show continues open this day (Thursday), and is highly worthy of a visit by all admirers of Carnations. The Roses on the second day, like many of the trees and plants in the Aquarium, will, of course, be dead or dying.

NOTES AND GLEANINGS.

It is gratifying to observe how much encouragement is being given to promote DOMESTIC FLORICULTURE IN LONDON. City flower shows are of weekly occurrence, and are doing

much, especially when patronised by ladies of rank and aided by the clergy, to improve the tastes of an important section of the community. One of the last of the city flower shows was held in the parish of St. Philip's, Clerkenwell, when H.R.H. the Marchioness of Lorne distributed the prizes; and Lord Selborne, speaking on the cultivation of flowers, remarked that "nothing was more important to religion and morality than the cultivation of what was natural, and pure, and beautiful. Natural tastes, natural manners, natural habits, natural affections were, they might depend upon it, much better than what was artificial, and therefore the love of nature was a great means of education, and he knew of no branch of the manifold varieties of natural objects more calculated to purify and sweeten the taste, and with the taste other qualities, than a love of flowers."

— At the meeting of the Prince Consort's Royal Association at Windsor on the 13th inst. Messrs. Sutton, the Queen's seedsmen, exhibited a beautiful collection of ANNUALS grown at their seed farm, Reading. It consisted of upwards of two hundred varieties.

— WELL may it be said that Kent is the garden of England, for Mr. Cannell states that his neighbour Mr. Vinson sent to market last Wednesday 2500 pecks of STRAWBERRIES. This, reckoning 14 lbs. to the peck, would amount to upwards of 15½ tons.

— THE BEDDING-OUT IN MR. RALLI'S garden at Cleveland House, Clapham Park, has been completed by Mr. Legg, who has won a foremost position by the excellence of his work in artistic garden decoration. In the planting of eight beds and a border fully 200,000 plants have been employed. They are arranged in a different, but none the less effective, manner than in former years. Mr. Legg is an originator, not a copyist, and modes of beautifying flower beds are annually seen in this garden which have not been seen before. By the kindness of the owner of the garden the public will have the privilege of inspecting the beds during Fridays in the months of August and September. It is expected that the garden will be open to visitors on the first Friday in August—not before—when a display of no ordinary character will be provided in these flowerless yet beautiful beds. The term "carpet bedding" is no longer applicable to some of these beds, for the bold yet clearly-defined irregularity of surface is foreign to the nature of a carpet, and artistic bedding becomes the more appropriate term. Some of the beds are extremely chaste and striking.

— SINCE there is evidence that the COLORADO BEETLE has by some means effected a passage across the Atlantic we must be prepared for rumours of an alarmist nature of its appearance in Britain. We are glad that the account which we cited from the *Daily News* last week of the appearance of the beetle at Dublin proved incorrect; but it is none the less necessary that a good look-out must be kept for the enemy to prevent its gaining a footing on our shores.

— WE regret to announce the DEATH OF MR. PETER DRUMMOND, late of Stirling, which took place at Wardie Road, Edinburgh, on the 9th inst. in the seventy-ninth year of his age. Mr. Drummond was for many years the head of the old-established nursery and seed business of W. Drummond and Sons; and it was mainly to his untiring energy that the house attained the wide reputation it acquired. With him the idea of forming an Agricultural Museum first originated; and he was also the founder of the Tract Institution at Stirling, which became so widely known throughout the world.

— WHAT in many seasons would be very commonplace becomes this season noteworthy—A CROP OF APPLES. We recently saw in the gardens of Munster House, Fulham, a long row of dwarf trees, every one of which is now laden with fruit. The trees are several years old, and on every branch of every tree the fruit hangs like "ropes of Onions." We do not remember ever observing a heavier crop of Apples on any trees. The soil is good and the situation low, and the blossom did not receive any protection. Every tree is of the same sort, and that sort the Hawthornden.

— WE record the DEATH OF MR. WOOD, late gardener at Ravensworth House, Fulham, for two reasons—first because of his great length of service in the same family, and secondly because of the unusual cause of his death, which resulted from he cutting of a corn and mortification ensuing. Mr. Wood was gardener at Ravensworth House first to the Hon. Thomas Liddell and subsequently to the late and the present Lord Ravensworth, his term of service extending over thirty-five years. He died on the 10th inst in his sixty-sixth year; he

was an industrious and trustworthy man, and was much respected in the neighbourhood in which he lived so long.

THE CAPER PLANT (CAPPARIS SPINOSA).

THE Caper grows abundantly in the south of Europe, along the shores and on the islands of the Mediterranean, and in Syria. It is generally found wild on walls and rocks; it is met with on the walls of Rome, Sienna, and Florence, and is extensively cultivated in the south of Europe, particularly between Marseilles and Toulon, and in many parts of Italy; but it is from Sicily that the greatest supply is brought. The flower buds form the Capers so much used as a pickle and a sauce, but in some parts the fruit is also employed. In the early part of summer the plant begins to flower, and the flowers continue to appear successively till the beginning of winter. The young flower buds are picked every morning, and as they

Fig. 18.—The Caper Plant (*Capparis spinosa*).

are gathered they are put into vinegar and salt; and this operation continues for six months, as long as the plants are in a flowering state. When the season closes, the buds are sorted according to their size and colour, the smallest and greenest being the best; these are again put into vinegar, and then packed-up for sale and exportation. Capers are stimulant, antiscorbutic, and are much employed as a condiment, but the medicinal virtues of the plant reside in the root, which is slightly bitter, somewhat acid and sour, and is diuretic.

The Caper is, according to Dr. Royle, the Hyssop of Scripture (*esob* or *esof*), "which springeth out of the wall," of which Solomon spoke. It produces long trailing branches of sufficient length to be used as a stick, on which the sponge filled with vinegar was offered to our Saviour when on the cross. "They filled a sponge with vinegar and put it upon Hyssop," says John (chap. xix. verse 29), and this accounts for the seeming discrepancy which some writers fancy they detect between John's and Matthew's account of the crucifixion, because the latter says they "put it on a reed." It is the same plant which was used by the children of Israel to sprinkle the blood on the door-posts at the institution of the Passover.—(*Hogg's Vegetable Kingdom*.)

WRITERS ON ENGLISH GARDENING.—No. 33.

ROBERT THOMPSON.

MR. THOMPSON was born at Echt in Aberdeenshire early in September, 1798. The precise date of his birth is not known, as at that period the birth registers of Scotland were not preserved with that care with which they are now. But from his baptism having been on the 16th of October in the same year, we may reckon with some degree of certainty that this ceremony was performed, as it usually is in Scotland, a month or six weeks after birth. His father was a small farmer, and

after he had received the solid education of his native parochial school he was placed under his uncle, who was gardener to Mr. Skene of Skene, where he was employed in the garden and plantations. He then removed to Haddo House, the seat of the Earl of Aberdeen, where he remained till 1820, and then left for the garden at Dunottar Castle, the residence of Lord Kennedy. After remaining there for one year he removed in November, 1821, to the gardens of Robert Ferguson, Esq., of Raith in Fifeshire, where he was for nearly three years.

In 1824 Mr. Thompson reached London, and went directly to the garden of the Royal Horticultural Society at Chiswick, to which he had been recommended by his late employer's brother, Sir R. Ferguson. The garden was then nearly completed; the collection of fruit trees had just been planted, some

of them, which were worked on Paradise stocks, were coming into fruit; and the walls which enclose the orchard and kitchen garden had then been just finished. Mr. Thompson was at once placed in the fruit department, which was then superintended by Mr. Christie, and no time could have been more opportune for his entering on his duties, as from the first he had under his observation the immense collection of fruits which then and subsequently has existed in the gardens. Early initiated by Mr. Knight and Mr. Sabine into a knowledge of the characters and merits of the then existing varieties, Mr. Thompson acquired a knowledge and taste for the study of fruits and fruit trees which increased with his years, and which he retained to the last. During the whole of the forty-four years of his active life at Chiswick pomology was his special

Fig. 19.—MR. ROBERT THOMPSON.

and passionate study, not only as it was exhibited under his eye in the garden, but in the literature and practice of the pursuit as existing on the Continent. It was this well-grounded and thorough knowledge of the subject which enabled Mr. Thompson so well to produce that laborious work, the "Catalogue of Fruits Cultivated in the Garden of the Horticultural Society of London," which has formed the foundation of modern pomological synonymy. No one except such a person as Mr. Thompson could have done this work so well. His proverbial patience and painstaking, his excessive care and caution, admirably fitted him for such a work, and stamp it with an authority which has never been assailed. It was not, however, in pomology alone that Mr. Thompson excelled. Every department of horticulture received from him its due share of attention; and not in the practice only, but also in the higher principles of the pursuit, did Mr. Thompson eminently shine. His love of physical science was equalled only by his love of gardening; and his knowledge of mathematics was of a high order. No better evidence of the combination of these qualities can be given than that which is furnished in that admirable compendium of horticulture "The Gar-

deners' Assistant." Meteorological science is much indebted to him for the constancy and correctness of the observations he conducted at Chiswick from 1830 till within a few months of his death, a period of thirty-nine years. And here we may take the opportunity of noticing a remark we sometimes have heard made by others who note meteorological observations. Doubts have been expressed as to the correctness of the instruments used at Chiswick. It has been said that the temperatures announced by Mr. Thompson were, when excessive, too high or too low, and that they did not correspond with those of other observers. It is, nevertheless, a striking fact that on an average of thirty years' observations—from 1826 to 1855—the difference in the records of mean temperature between Chiswick and Greenwich amounts only to 0.06°—a lasting tribute to the care with which the Chiswick meteorological observations were made.

Mr. Thompson was a voluminous writer, though he does not appear as the author of many works. In the "Transactions of the Horticultural Society," besides the bulky meteorological tables, there are many valuable papers on horticultural subjects. To Loudon's "Gardener's Magazine," the *Gardeners'*

Chronicle, the "Edinburgh Philosophical Magazine," and other periodical publications he was a frequent contributor. In the preparation of most of his great works Mr. London acknowledges the aid rendered by Mr. Thompson, and especially in the "Encyclopædia of Gardening" and the "Suburban Horticulturist." He contributed also to the "Penny Cyclopædia," Morton's "Cyclopædia of Agriculture," Maunder's "Treasury of Botany," and we believe he was the sole author of the letter-press of the "Pomological Magazine."

Towards the close of his career a tribute to the services he had rendered to horticulture was paid to Mr. Thompson, by the presentation of a testimonial, amounting to the sum of £400, raised by public subscription, and on the end of his active services in connection with the Royal Horticultural Society he retired on full pay. He died on the 7th of September, 1869.

A portrait—as good as is obtainable—of this excellent gardener, able writer, and worthy man will be acceptable to many, especially to the great number of our readers who have profited by his practice and teachings.

AN ELECTION OF TEA ROSES.

IN your issue for June 28th I observe that Mr. Hinton has again undertaken his labour of love—the Rose election, or rather the exhibition Rose election. I am sure all amateur cultivators of the Rose feel deeply grateful to Mr. Hinton for his great trouble in bringing thus periodically before us the *crème de la crème* of Flora's queen. I for one return him my most sincere thanks, as I have been profited and greatly interested in former elections, so I shall look forward anxiously to the declaration of the poll in the present one. I much wish for an election of those fair jewels the upper ten of our queen's court—viz., Tea Roses. The question I propose would be, Name the best twenty-four exhibition Tea Roses, marking the twelve hardiest, best growers, and freest bloomers.

Can any of your readers give me their experience of Abel Grand as two-year-old cut-backs? With me it barely manages to exist after the first year, each shoot after being pruned dying back several inches before pushing a bud, and then in a most weakly manner. The plants are on the Manetti; my soil being a light sandy loam on gravel.

Yet another question. Has anyone observed that the shoot on which zinc labels are tied dies? With me fully seven-tenths of them do so. How is this? They are tied on quite loosely, some with tarred twine and others with lead wire.—A TYRO, Co. Down.

[To this proposition I hardly know how to reply. But firstly, gratefully as to the kind expressions bestowed on past labours; secondly, hopefully as to the exhibition election, in which I fancy there will be even harder labour than heretofore, but in which I shall still try to do justice to the queen of flowers; lastly, in a spirit of procrastination. Acknowledging all the loveliness of the Teas, I feel that I shall have my hands full; but if spared to try another year, such an election as the one proposed with one of best garden Roses is what I thought would be useful.]

As to Abel Grand, my experience is that it does not like the Manetti. I should say, Try it on its own roots or on the seedling Briar.

I cannot explain the injuriousness of zinc labels, and certainly have not noticed it. I rarely tie my labels on the plant itself, but on a stick close by.—JOSEPH HINTON.]

WASPS.

WASPS are a great annoyance to any person who has fine fruit, for they not only destroy the fruit, but one is not safe in pulling Plums, Apricots, &c., from being stung. I was very much troubled with wasps when gardener to the Earl of Wemyss, but I waged war against them in real earnest, and the fruit was saved. Besides killing all the queen wasps that could be caught in April and May, about the middle of July when the nests were getting strong so that there was no difficulty in seeing them, during a calm sunny day I went with four men and walked over the plantation and burnside near to the garden, and as soon as a nest was found a stick with a white rag on it was stuck up, and the following day two men were sent to kill it; and if thirty nests were destroyed the men took thirty full-sized bottles about half-full of water and plenty of strong match paper made with saltpetre and coarse paper. Sixpence-worth will do for a hundred nests. It is safe to be liberal with the match paper, or the wasps might

not inhale enough to sicken them; and on digging out the nest, if they can fly, they will attack anyone near them, but if the digging the nest is carefully done not one wasp will get out. In setting fire to the match and when fairly burning, a bit of turf to keep in the smoke should be put on the hole for three minutes, and then knock them into jelly; and sink a bottle as near the nest as possible quite level with the ground, and the wasps will tumble in at railway speed, and if the nest is not very strong one bottle will hold all the wasps, but in September it will require two bottles. I have seen two crammed and about 1200 in each. The wasps coming in from their work seldom or never attempt to sting, unless the nest is under a bush; but if a nest is opened and the wasps have not enough of smoke to sicken them, and they happen to come out a retreat is necessary; but if gloves are used and a veil, then one can dig away with impunity. One season upwards of three hundred nests were killed at Gosford.—J. ADDISON, Ormiston, Edinburgh.

NEWCASTLE BOTANICAL AND HORTICULTURAL SOCIETY'S SUMMER SHOW.

AFTER a career extending over half a century this Society has latterly exhibited new life, and has given a great impetus to horticulture, in the north particularly, while it has not been without influence in the country generally, for it has secured support from the south as well as the north, and which has enabled the Society to provide the best show ever held in Newcastle. The Hon. Secretaries, Mr. Taylor and Mr. French, are evidently believers in the old French adage that "Heaven helps those who help themselves," and they, with the aid of an able Committee, commenced working in a zealous and withal systematic manner. Their object was to devise a plan which promised to provide a great horticultural display at a moderate charge, and to fix a deserving public institution on a solid foundation. The results have been extremely gratifying, for no less than 1300 new members were enrolled under the new system in less than two months, and at the time of the spring Show the list of members contained about 1500 names. The number has since doubled, and there is at present upwards of 3000 members, whose subscriptions yield about £1500. It is pleasing to note that the scope of the Society extends beyond exhibitions, for besides providing three shows annually—in the spring, summer, and autumn, the Society aids the Flower Mission and the Children's Flower Show and Window Gardening; and we understand that it contemplates conferring a benefit upon the public by planting in the Leazes Park a considerable number of fine trees to be brought from abroad.

The last and greatest show was held in Leazes Park, and it appears to have been as successful as it was extensive and well arranged. The plants, &c., were grouped in five marquees, placed parallel to each other, containing 20,000 square feet, and so arranged as to display the contents of all at one time, except where the view was intentionally broken by Fuchsias and other light and graceful plants. All woodwork was covered with paper, the whole having been handsomely decorated by Messrs. Carnegie & Gullachsen. The flowers, &c., both in quantity and quality, were equal to those seen at the best exhibitions of the year. During the two days of the Exhibition there was nearly twenty thousand visitors. Nearly nine thousand persons entered the show ground during the second day. Between noon and four o'clock, when the admission was 1s., the amount received at the gates was £70, and the sum realised by the 6d. rate in the course of the evening was £142. On the first day £258 was taken, making a total of £470 paid for admission during the two days. Since Monday week £130 has been paid by the new members, so that there will be handed to Mr. Councillor Gray (the Hon. Treasurer and also the Chairman of the Society), the sum of £600 which the Society has received within ten days. Yet while commanding an income probably ten times the amount of that which it formerly had at its disposal, the Society has, of course, increased the value of its premiums to a very great extent. For instance, for a collection of greenhouse plants, to which the sum of 7s. 6d. was awarded in 1872, £10 is now given, and the total amount of premiums, which was formerly perhaps not more than £60, is for the present Show £550. The general expenses of the Exhibition have also largely increased—the total cost of the Show is estimated at £800, and exceeds the subscription income; but a favourable balance is secured by the money paid for admission, whilst the large additions which are expected to be made to the membership will, it is confidently anticipated, place the Society in a sound condition financially. The backwardness of the season in the north of England has retarded the growth of nearly all kinds of plants and flowers. Local exhibitors, though they showed well, were therefore scarcely up to the standard of some former years, and the splendour of the Show was in a great measure due to the numerous entries of floral cultivators in the south.

Amongst the exhibitors who did not compete, and whose contributions occupied the circular or entrance tent, there were Mr. B. S. Williams of Victoria Nurseries, Upper Holloway, London; Mr. Watson of Fenham Nurseries; Messrs. S. Nairn & Son, Pilgrim Street; and Mr. Isaac Charlton, South Parade Nursery, Newcastle; Messrs. Stuart & Mein, Kelso; Messrs. Birkenhead, Sale Nurseries, near Manchester, and many exhibitors of garden requisites. Mr. B. S. Williams staged in the central entrance marquee a handsome collection of plants, many of them not yet in commerce. Sixteen of the plants were sold for a hundred guineas to one of the officials of the Show, Colonel Joicey of Newton Hall, and many other large sales were effected by the different nurserymen present. A very concise catalogue containing an alphabetical list of all the exhibitors, also the position they held in each class, was issued immediately after the awards were made.

The following were the successful exhibitors in the classes for plants:—The prize (£10 and the Silver Knightian Medal) for six plants in bloom was gained by Mr. E. Tudgey, gardener to T. F. G. Williams, Esq., Henwick Grange, Worcester; and Mr. R. Sleightholme, Armley, Leeds, was the winner of the first honour, £5, for three plants in bloom. The first prizes for ornamental-foliaged plants were won by Mr. Tudgey and Mr. A. Methven, gardener to Mr. Theodore Lange, Heathfield, Gateshead. The winners of first prizes for Ferns were Mr. Tudgey and Mr. T. Wilson, Normanby Hall, Middlesbrough. The chief honours in other classes of plants were won by Mr. Tudgey; Mr. Sleightholme, gardener to Mrs. Wood, Armley, Leeds; Mr. Henry May, Bedale; Mr. James Sanderson, gardener to Mr. W. H. Parker, The Elms, Gosforth; Mr. George Stockley, Elswick Park; Mr. W. Moul, gardener to Earl Ravensworth, Ravensworth Castle; Mr. J. Herbert, Grammar School, Durham; Mr. P. Sherwin, gardener to Mr. J. Young, Netherford; Mr. Thos. Battensby, Haghill (Bronze Knightian medal), and Mr. George Murray, Dipton.

CUT FLOWERS.—Of these the Roses were the chief exhibits. Many splendid blooms were staged, and no part of the Show was more greatly enjoyed by the visitors than the Rose classes. The county prize of £5 and silver Banksian medal were won by Mr. C. Turner, Slough, in the class for forty-eight blooms in not less than twenty-four varieties, followed by Messrs. G. Davison and Co., Hereford, who were placed second, and Messrs. Cranston and Co. third. The Mayor's prize for thirty-six Roses was won by Messrs. Cranston & Co., Mr. Turner second, and Messrs. Davison third. They held precisely the same positions in the class for twenty-four blooms; while for twelve blooms Messrs. Davison & Co. had the premier place, as they were also in the class for Tea-scented Roses, Mr. Turner second, and Mr. Whitwell, Barton Hall, Darlington, third. Mr. Thomas Flowdy, Gateshead, won the chief prizes for yellow Roses, and Mr. Laws, Ponteland, was awarded the first prize and bronze Banksian medal for twelve blooms with buds attached. Amongst other winners of prizes for cut flowers were Mr. John Harland, Arthur's Hill; Mr. R. Scott, Arthur's Hill; Mr. W. J. Watson, Fenham; and Mr. W. Moul.

The silver cup presented by the President, Major Woods, for the best and most tastefully arranged table decoration of flowers, plants, and fruits, was gained by Mr. M. Thompson, gardener to Mr. Lindsay Wood of South Hill, and the second prize was won by Mr. J. Gellender, Newcastle. Amongst the other winners of prizes for table decorations were Mr. R. Sleightholme, Mr. E. Tudgey, Mr. M. Larke, gardener to the Rev. R. F. Wheeler, Whitley Vicarage; Mr. A. Develen, gardener to Mr. Joseph Davison, Benton; and Mr. Thomas Ramshaw, Dryburn, Durham.

FRUIT.—The principal prizewinners were Mr. Wm. Moul; Mr. C. H. Letts, gardener to the Earl of Zetland, Upleatham; Mr. John Hutchinson, gardener to J. J. Hunter, Esq., Whickham Grove; Mr. Thomas Wilson; Mr. J. R. Jowsey, Sedbury Park, Richmond; and Mr. R. Lundt.

The officials of forty-one horticultural societies in Northumberland and Durham were invited to the Show, and 260 boys from the *Wellington* training ship, under the command of Capt. Roccock, attended the Exhibition and went through their evolutions in front of the marquees.

ROSES EUGÉNIE VERDIER AND MDLLE. MARIE FINGER.

Will you allow me to enter a protest against the idea, started by "WYLD SAVAGE" and endorsed by Mr. Hinton, that E. Verdier and Marie Finger are the same Rose under different names? Can it be that "WYLD SAVAGE" has no eye for colour, or is it that he has not grown Marie Finger in a sufficiently large quantity to form a correct judgment? I have had two lines of these two Roses side by side this season, and can most positively affirm that Marie Finger is at least two shades darker than Eugénie Verdier as grown here. As a Rose I consider the former superior to the latter in every way.

It is of better habit, freer growth, and the flower is much more lasting and of better shape; and I think the majority of rosarians will agree with me that it is one of the best light-coloured Roses yet introduced, lacking only perfume to make it perfect. I should be glad to hear what others think, as it would be a pity to confound Roses together that are really distinct.—R. W. BEACHEY.

WEST OF SCOTLAND ROSARIAN SOCIETY'S SHOW, HELENSBURGH.

THERE are few things that to my mind show the hold that the Rose has, I will not say on the general public, but on those who really love flowers, than the institution and successful carrying-out of such a show as this. In a country of which, as the worthy Chairman of the day said, an Englishman is reported to have declared "that it had no climate at all and the weather was beastly," and where at any rate the average rainfall is double that of the south of England, and where south-west gales are so prevalent that they threaten to blow the Roses off the bushes, not only do they manage a Rose Show but offer such prizes as to induce some of our leading growers to compete at them; and it was a real pleasure to meet Mr. George Paul and Mr. Cant in the streets of Helensburgh, and to see them busy staging their Roses in the skating rink; for taught by past experience the promoters of the Show, instead of holding it in a tent as last year, had migrated to the rink, which proved a very excellent place for it. The room was commodious, and owing to one side being thrown open more light was admitted than in ordinary cases where shows are held in a room, while it also afforded room for a promenade. The Show was truly international as far as the British Isles were concerned, for not only were there English but Irish growers competing with the natives. These latter were under a great disadvantage. The season has been late everywhere, but later in Scotland than in England, and hence this date (July 13th) which had been fixed upon as one most likely to suit Scotch growers was fully a fortnight too soon. I drove round the Gareloch and walked about Helensburgh before the Show and saw no Roses, and my wonder was that so many were enabled to put in an appearance.

Messrs. Paul and Cant contributed two stands of forty-eight blooms in their usual style and far outdistanced their competitors, although the Messrs. Dobson's stand was a very creditable one. Unfortunately Mr. Cant's, owing to an irregularity, was disqualified. Both contained some very grand flowers. François Treyve, Duke of Edinburgh, Etienne Levet, Paul Neron, Marie Cointet, Thérèse Levet, Mons. E. Y. Teas, Annie Wood, John Hopper, François Michelon, and other well-known sorts being in good form, especially for the season, which is not a favourable one for the Rose. In the class for twelve new Roses the same competitors appeared; and good blooms were shown by Mr. George Paul of some of the new varieties emanating from Cheshunt—Dr. Hooker, Duke of Connaught, Mrs. Laxton, Marchioness of Exeter, and others, while Mr. Cant showed a stand of English and foreign raised varieties of great excellence. In the class for twelve blooms of any one Rose the first and second prizes went to Marie Baumann, and the third to La France. In the amateurs' classes the first prizes were taken in every instance by an Irish grower, Mr. Hawkins of Belfast, with flowers of considerable merit, and the home growers made a very fair display under all the difficulties they had to contend with. A step in advance has been made since last year by offering prizes for blooms without any adventitious foliage; and we can only hope that the strong expressions made on this subject will produce fruit, and that this flourishing Society may set the good example of discountenancing all additions to the flowers.

The warm-hearted hospitality and kindness which one met with was something remarkable, and made my sojourn of a few days a most happy one; and I am sure all of us Sassenachs retain a most lively and pleasant recollection of the West of Scotland Rosarian Society's Show, which the energy of Mr. Galloway, so well known in the south for his triumphs as a *Gladiolus* grower, have tended to make so successful.—D., Deal.

RICHARDIA ÆTHIOPICA.

Two years ago I turned one plant of it out of its pot into a pond where it was about 18 inches deep. It was cut down by the frost, and there was for some time a thick coat of ice over it. But it flowered so well in summer that I put out some more plants last autumn. They were all cut down below the surface of the water, but are now in strong foliage with five or six flowers or large buds on them, and make a very handsome ornament on the edge of my pond. The foliage is not so large as on plants when well grown in a greenhouse, but very healthy. I purpose turning out a good many more this year. As I am living in the county Donegal (in the extreme north of

Ireland), growing it in that manner here is putting it to a very severe test.—JOHN R. BORD.

HIGHGATE FLOWER SHOW.

THE annual Exhibition of the Highgate Horticultural Society took place on the 12th inst. in the beautiful grounds of Edward Brooke, Esq., J.P., Caen Wood Towers. A more charming place for a flower show would be hard to find, for fine views are commanded from every part of the grounds, with London as it were lying at your feet. The Exhibition was held in two large tents, the larger one for specimen plants and gardeners' produce, the other for amateurs' and cottagers' produce. On entering, the first group to attract attention was a collection of foliage plants and Palms, edged 3 feet wide with dwarf Roses in pots in bloom from W. Outhush & Sons of Highgate and Barnet. At the other end Mr. B. S. Williams of Upper Holloway exhibited an unique group of six very fine specimens of *Allamanda grandiflora*, *Statice profusa*, *Dipladenia Brearleyana*, *Erica obtata*, *Ixora javanica floribunda*, and *Bougainvillea glabra*, edged with graceful Palms, Ferns, and new and rare plants, such as *Cocos Weddelliana*, *Adiantum gracillimum*, various new *Crotons*, *Dracenas*, &c.

The best competition was for the special prize given by S. Cumming, Esq., for twenty plants, distinct. Mr. Sheen, gardener to E. Brooks, Esq., Caen Wood Towers, was placed first, having good plants of *Dicksonia antarctica*, *Croton variegatum*, *Adiantum farleyense*, *Alocasia macrorrhiza variegata*, *Stephanotis floribunda*, &c. Mr. Fuller, gardener to E. J. Nettlefold, Esq., The Grove, Highgate, was placed second with much fresher plants, but not so large; he had a good *Stephanotis grandiflora*, *Clerodendron Balfouri*, a bright *Croton majesticum*, *Alocasia metallica*, *Crotons Weismanni* and *variegatum*, *Sanchezia nobilis*, &c. Third, Mr. F. Newman, gardener to W. H. Michael, Esq., Cholmeley Park, with *Thrinax elegans*, *Yucca aloifolia*, *Adiantum farleyense* and *cuneatum*, *Davallia Mooreana*, &c. For six Palms Mr. E. Ayling, gardener to S. Cumming, &c., Harbeston, was first with *Cocos Weddelliana*, *C. nucifera*, *Demonorops palembanica*, *Lantana borbonica*, and *Areca lutescens*. Mr. Fuller was second, having a good *Chamerops humilis*, *Areca lutescens*, *Seaforthia elegans*, &c. Mr. S. Clarke, gardener to Sir S. H. Waterlow, Bart., Fairseat House, was third. For six Ferns Mr. Sheen was first with excellent plants of *Cyathea medullaris*, *Alsophila excelsa*, *Dicksonia antarctica*, &c. Mr. Clark was second and Mr. Ayling third, also with clean and well-grown plants. Four Ferns, first Mr. Sparks, gardener to J. W. Jeakes, Esq.; second Mr. Shepherd. Six *Caladiums*, first Mr. Bullen; second Mr. Branderick, gardener to R. Prance, Esq., Hampstead. Four stove and greenhouse plants, first Mr. Branderick, second Mr. Sparkes. Six foliage plants, Mr. Ayling first and Mr. Branderick second. Six table plants, first Mr. Sheen, second Mr. Ayling. Three table plants, first Mr. Fuller, second Mr. Sheen, third Mr. Ayling. For six Cockscombs Mr. Kent, gardener to J. Lane, Esq., was a long way ahead with six grand plants; second Mr. Clark, third Mr. Taylor. Six *Achimenes*, Mr. Fuller was first. Six *Gloxinias*, Mr. Newman was first. Six zonal *Geraniums*, Mr. Catley, gardener to Mrs. Lermitt, Finchley, showed very fine plants. Six variegated *Geraniums*, first Mr. Taylor. Six *Pelargoniums*, first Mr. Pope. Twelve British Ferns, first Mr. Shepherd. Twelve bunches of cut flowers, first Mr. Fuller, second Mr. Ayling, third Mr. Rowson. Twelve cut blooms of Roses, first Mr. Taylor, second Mr. Shepherd. Twenty-four blooms, Mr. Eason was first, Mr. Silvester second.

FRUIT.—Mr. Akehurst, gardener to S. Copestake, Esq., showed three bunches of Black Hamburgh Grapes not for competition, by far the finest in the Show. For Black Grapes Mr. Clark was first, and for White Grapes Mr. Branderick had premier honours. For six Peaches Mr. Clark was first, Mr. Fuller second, and Mr. Sparkes third. Six Nectarines, Mr. Fuller first, and Mr. Birse second. Three dishes of Strawberries, Mr. Sheen first. Collection of Fruit, Mr. Birse was first; he had also the same position for a collection of Fruit and Vegetables. Second Mr. Clarke, third Mr. Sparkes.

The Baroness Burdett Coutts gave several special prizes for kindness to birds, &c., likewise the cottagers and amateurs showed well; but it would take up too much space to mention all prizetakers. The Show was a very successful one and reflected credit on Mr. Buick the Secretary; and was visited by several thousand people during the afternoon and evening.

MAIDENHAIR FERN.

It may interest the Editors of our Journal and "WILD SAVAGE" (vide vol. xxxii., page 64) to know that on Saturday last (July 7th) I found *Adiantum Capillus-Veneris* growing in Portland, and as "seeing is believing," I send a small piece in a tin box for your inspection.

I have not yet discovered *Asplenium marinum*, but a nur-

serymen who used to live in Weymouth showed me plants from the same locality. I gladly record this, as the Fern books give Dorsetshire credit for only the commonest kinds.—CHAS. T. HALL, Osmington, Weymouth.

[The specimen sent though small is true.—Eds.]

LUDLOW ROSE SHOW.

THERE was held on the 12th inst. in the Assembly Room, Ludlow, a little town picturesquely situated on an eminence (Did not our Rose boxes find this out?), about midway between Shrewsbury and Hereford, a most enjoyable and in every respect, floriculturally and financially, a successful Rose Show *pur et simple*, well worthy of being chronicled in more than a passing notice in the annals of our Rose Journal; if only *pour encourager les autres*, and to induce other provincial towns to realise what an inexhaustible fund of pleasure may be their own by calling into life an annual Rose show. For if the proud Salopians (and fairly are they so entitled), have achieved for themselves so signal a success without any exceptional circumstances in the way of celebrated local nurserymen or amateurs, why may not scores of other provincial towns be moved by the contagion of this good example to go and do likewise? Indeed, without assuming the garment of prophecy, every observer of the past history of the Rose must allow that its whole success depends on these provincial gatherings. They are the little pebbles thrown in here and there, producing a diversity of fresh circles, but all eventually merging in one grand central brotherly embrace—the very life blood of her roseate majesty, of which the National Rose Society is both the offspring and the parent. The mountain—Mahomet was said to complain—would not come to him, so he had to go to the mountain; and just so many an unfledged exhibitor who would not dare to scale the uphill task of reaching the National, would by means of his own provincial show gradually gain in confidence, skill, and experience, aye even to carry back home the chief laurels of Queen Flora's highest court.

But to return to the Ludlow Provincial Show, happily not in the clouds but an accomplished fact. A first glance of the schedule would suffice to show that it was framed on the lines of the West of England Rose Show. Very proud indeed is that Society of its offspring, and very strong did the Herefordshire contingent muster on that auspicious occasion. Messrs. Cranston & Co. were competing at four different shows, and either were not cutting their usual strength or underrated their rivals, for they had to be content with second honours, though there were some grand blooms in their exhibits, notably Hybrid Perpetual Thomas Mills, an indescribably grand bloom of François Michelin, perfection of size and smoothness; also Maurice Bernardin, shown so different that our friend of Warminster must hesitate about classing him with his other four pseudo-suggested synonyms. Mr. W. Lee of Lyonshall Nurseries, Kingston (who formerly belonged to the King's Acre staff) was *facile princeps* in all three open classes; indeed, it is to be doubted whether grander, smoother, and deeper-coloured blooms have been shown this year. Specially noticeable were Sénateur Vaisse, in great substance of petal and colour; Camille Bernardin, nearly equal to Mr. Jowitt's at Hereford; Charles Rouillard, a superb specimen of this shy but exquisite model of a Rose; Marquise de Mortemart, grand; Horace Vernet, Duke of Wellington, and Lord Macaulay, each of intensely glowing colour and great substance; Mons. Furtado and Lælia, splendid specimens; and last, but not least, Elie Morel, of a colour approaching carmine, a marvellous bloom, and very puzzling to the Judges. Mr. Lee assured them that it was an undoubted specimen of this light pink variety, but attributes his depth of colour running through nearly all his three boxes to a liberal top-dressing of soot to his Manetti maidens (budded Manetti of the first year?) in the spring just before they began to break. Doubtless this may partly be the reason, but Mr. Lee's strong-holding red deep clay on gravel or marl plays an important part as regards enriching the colour of his blooms. Mr. Griffiths of Tillington Nursery (where Andrew Knight grew most of his pomological novelties) took a good second prize, his stand containing grand blooms of Madame Hippolyte Jamin; Reynolds Hole, a superb bloom; and Thomas Mills, a Rose which deserves wider cultivation.

AMATEURS.—Mr. Jowitt, as may be supposed, carried off two of the first open prizes in thirty-six varieties. Very good indeed were Marie Rady, Mons. Bonstetten, Hippolyte Jamin, especially grand and symmetrical. The Rev. C. H. Bulmer was second. In his stand were grand blooms of Beauty of Waltham; J. Stuart Mill, one of our greatest recent acquisitions in crimson Roses; and Mons. Woolfield. Mr. J. H. Arkwright was first in twenty-four varieties. This gentleman also exhibited—besides his irrepressible Maréchal Niels, which command first prizes wherever exhibited, and which for the benefit of exhibitors at late and early shows I may mention are grown on trellises in a recess facing south between two gables—a box of twenty-two

varieties of old Roses, which would have gladdened the heart of the Marquis of Bute, who once gave a prize at Hereford for such old varieties. The stand was exquisitely grouped, and contained varieties, now seldom seen, of the old Austrian Briar in three shades, the white and pink Provence, the old red indica, the yellow, orange, and pink Persian, the old Maiden's Blush, several varieties of the old Moss, China, &c. The class locally restricted was neither as well filled or exhibited as doubtless will be on future occasions, as the prize list is liberal. Next year a larger prize to nurserymen in the open class would attract the Rose chiefs of a distance and be of mutual advantage, as the county of Salop is admirably adapted for Rose culture, and as yet little has been enterprised.

The only remark to be made in concluding this sketch is to congratulate the Committee and Mr. Salwey, the courteous Hon. Sec., in particular, on the success of their very excellent Exhibition, and to suggest that on a future occasion it be held in the grounds of Ludlow Castle, a locality that would lend wonderful enchantment to the scene from its natural picturesqueness, from its association as formerly a Royal residence, and from its being the favoured spot where Milton wrote his "Comus."—THE HEREFORDSHIRE INCUMBENT.

THE BURGHLEY YELLOW ROSE.

I SHALL only feel too happy to tell your correspondent "SOUTH LINCOLN" the best way I know to flower the Burghley Rose. If your correspondent grows fruit trees on the wall of his garden, I would advise him to procure good layers of this Rose and plant them between the trees, but not to forget the larder. When established this Rose grows something like *Maréchal Niel*, from 10 to 15 feet in a summer. Grow-up a single stem between the trees, and when it reaches to the top of the wall train it along it, and when the dark days of winter set in take the Rose away from the wall and tie it to the Pear or Plum spurs. This will effectually preserve it from the frost. When the fruit trees are in flower the Roses will be showing, and the fruit blossoms keep it warm and comfortable. In due time you will see the yellow buds of the Rose peering through the green leaves, which add the necessary shade and all comes perfect. Many people wonder at the green eyes which the *Maréchal* shows when exposed to a powerful sun all day and a frost at night, but if they think a wee the reason is simple enough. I may add that no letters of thanks are needed, I have so many from "the Royal" that they have become common.—R. GILBERT.

[We have inquiries whether the Burghley Yellow will grow and flower if budded on the Briar. Will Mr. Gilbert oblige by informing us if he has adopted that mode of culture?—EDS.]

CLIFTON ROSE SHOW.

A VERY pretty little Rose Show was held at Clifton on the 12th inst., which was successful in every way. It was held in the gardens of the Zoological Society, and a prettier place for such a show cannot be imagined. The prizes, particularly for amateurs, were very poor, but that did not prevent a large and goodly muster of rosarians.

Among the nurserymen were Mr. Keynes of Salisbury, Mr. Cranston of Hereford, Mr. Corp of Oxford, Mr. Durbin of Bath, Mr. Bennett of Stapleford, and Mr. Curtis of Torquay, so that the nurserymen's classes were well filled, and if no other exhibitors had been there, still a good exhibition of Roses would have been the result. But when to these are added the names of such amateurs as Mr. Baker of Heavitree, Mr. Jowitt of Exeter, Mr. Davis of Wilton, Mr. Chard of Clarendon Park, and a host of others, you may imagine that there was no lack of Roses. The nurserymen filled one tent and the amateurs another, and it was very interesting to compare the effects of the stands in the one with the other, and to see in what one section failed and the others succeeded.

There was no class for seventy-two distinct varieties, the highest class for nurserymen being the one for forty-eight trebles, and for this three exhibitors staged. Mr. Keynes won the first prize very easily, but his blooms were not, in my opinion, quite up to his old standard; but then we are getting late on in the season. Mr. Cranston was second and Mr. Curtis third. Mr. Keynes showed a treble of *La Rosière*, a new Rose, which I admired at the Crystal Palace, but here it was only a poor *Camille de Rohan* or *Souvenir de Dr. Jamin*. He had several good trebles of *Teas*, and most of his blooms were clean and even, but a little undersized. He showed also a good treble of that difficult Rose to open *Black Prince*. For twenty-four trebles confined to Bristol nurserymen four candidates put in an appearance, and a more miserable lot than the generality of the blooms I never judged. Mr. Durbin's were a long way the best, but he spoilt his box by putting a treble in the back row of

such a wretched Rose as *Abbé Bramerel*, and one or two more flat and coarse blooms also were sad eyesores; but the other Bristol nurserymen would have been wiser to have kept their blooms at home than to have made such an exhibition as they did. I do not at all approve of these close classes, and wish secretaries and committees would set their faces against them. Often and often have I seen money positively thrown away, the exhibits being quite unworthy of a prize, but the committee feeling compelled to award them prizes.

For the class for twenty-four distinct Roses (nurserymen) there was great competition, for eight good stands were staged, and we had no light task to decide on the second and third prizes. Mr. Corp of Oxford won the first prize with a splendid box. To my thinking this stand was by far the best in the Show. He had marvellous colour, good form, freshness, and indeed all good qualities which a Rose can possess. His most remarkable blooms were the novelties *Margaret Brassac* and *Mons. E. Y. Teas*. His *Charles Lefebvre* also was the best I have seen this year. Here we saw the Rose as described by "D. Deal," as he saw it at Okeford Fitzpaine; each petal shaded with velvet, and the form pure centifolia. He had also a grand bloom of *Marie Baumann*; indeed, his stand was very like what we have been accustomed to see Mr. Baker show. *Hercules* was once more first for twenty-four and twelve trebles, and very fine they were, but perhaps a little overpast. The *Teas* were exceedingly good, and altogether it was a very successful Show.—WYLD SAVAGE.

ROSES IN HAMPSHIRE.

I HAVE noticed just now very general complaints of the present year (1877) being a late and bad year for the queen of flowers. This I am forced to concede must be generally the case. I went to the Crystal Palace Show, hoping to be very much pleased; I came away disappointed. I venture to record my experience. I am an amateur, living in Hampshire within a mile of the Solent, on a soil light and gravelly 1 foot or 18 inches deep; subsoil a hungry, open, clean gravel or shingle, one that you would almost think it hopeless to grow *Roses* in. I have nevertheless attempted it, and succeeded sufficiently well to induce me to continue the enterprise. I have about 250 *Roses* in my garden, principally on the Briar and *Manetti* stocks, but some few on their own roots. I have none on the Maiden Briar.

With the soil as described above, as may be expected, the *Manetti* answers best, care of course having to be taken to eradicate shoots from the stock, which it is very apt to make, and which if allowed to remain growing will in a short time very much weaken if not destroy the scion. The Briar loving a stiff loamy soil has not succeeded so well. The same may be said of self-rooted *Roses*, which like a rich loam.

This season has been with me excellent. I never had such a number of good blooms; without any special cultivation I could have brought a case which I should not have been ashamed of exhibiting against the smaller amateurs at the Crystal Palace. I send a few extracts from my garden memoranda for this year (1877):—May 16th, *Yellow Banksian* in bloom; 19th, *Pink China* in bloom; 25th, cut *Devoniensis* and *John Hopper*; 28th, cut *Gloire de Dijon*, *John Hopper*, *Devoniensis*, and *Lord Clyde*; June 3rd, cut *Charles Lefebvre*; June 9th, splendid show of *Climbing Devoniensis*, *Gloire de Dijon*, *John Hopper*, *Charles Lefebvre*, *Lord Clyde*, and *Duke of Wellington*—several exhibition blooms; June 15th, 105 blooms of above in front of house, besides a profusion of buds, blooms to a large extent having been previously cut.

Since the above date I have had a magnificent show of *Roses* all blooming together, so much so that I have remarked to many of my friends that I have been much better pleased with the show of *Roses* in my own garden than with that at the Crystal Palace. I do not profess to obtain every new Rose as it comes out. I am satisfied with such as *Charles Lefebvre*, *Climbing Devoniensis*, *John Hopper*, *Madame Lacharme*, *Jules Margottin*, *Prince Camille de Rohan*, *Baroness Rothschild*, *La France*, and *Roses* of that character. I have had perfect pictures of dwarf bushes on the *Manetti* of "the Baroness," *Fisher Holmes*, *Duke of Edinburgh*, *Général Jacqueminot*, and *Madame Lacharme*, a dozen perfect flowers expanding at once in some instances. I take it that the true aim of a cultivator of flowers should be to select those which are good and to grow them well, so as to please the eye, not to run about collecting plants the same or nearly so as those that have come before, distinctions without a difference, multiplying names with scarcely any variation of flower. The culture I have adopted is this: I manure highly with stable manure a year or two previous to planting, cut back hard annually in March

and with such a winter and spring as we have had refrain from watering entirely. Mine have not had a drop except what nature has given. About every two years I cover the Rose quarter 2 or 3 inches thick with stable manure in October or November, and shift all the plants by trenching the ground and digging in the manure and replanting in March at the time they are pruned back. Watering I have observed gives a tendency to mildew, with which they have been affected in previous years. I have seen none in this, and scarcely any aphid or other blight. The Roses may be characterised as perfectly clean, in fact pictures as to foliage.—CONSTANT SUBSCRIBER, *South Hants*.

[Do not hesitate to communicate your experiences in Pear and Apple-growing, especially as, unlike many cultivators, you "have a good crop of each."—EDS.]

DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

KITCHEN GARDEN.

We have given over trying to produce Cauliflowers as an autumn crop, but those who find it necessary to make sure of good examples at that time should now put out their plants. To make sure of good results the plants ought not to become stunted in their growth by overdryness at the roots, which is certain to produce mildew, and caterpillars ought to be destroyed if they are observed on the plants. Hand picking is the most certain way. A friend recommended ducks to us as a sure way of clearing crops of caterpillars; but we found on turning them into the garden that they cleared-off Peas, Cabbages, Lettuce, and caterpillars indiscriminately. Hens, too, we were told would soon clear the Rose bushes of aphid, but our hens prefer to scratch the plants out by the roots in their search for underground insects. It is best not to allow any sort of poultry in the garden. The autumn-sown Onions are nearly ripe; a few specimens have thick necks and stand upright. A good plan is to bend the tops down so as to cause the bulbs to swell and ripen more rapidly. Spring-sown crops have been gone over and all the weeds removed.

Brussels Sprouts and Savoys have been planted-out on good ground, the Sprouts 2 feet apart, and the Savoys 2 feet between the rows and a foot between the plants. Cardoons should now be thinned-out, leaving the plants at the distance of 9 inches apart in the rows. The ground should be stirred-up a little amongst the plants, and all weeds be removed. As the plants increase in growth they must be earthed-up a little at a time when the ground is dry. We have planted some Kidney Beans for a late crop. This sowing when the weather is favourable in September and October is very useful to us. The plants will continue bearing into October, but it is quite necessary to gather the pods as soon as they are fit for use. Turnips ought also to be sown for use in autumn and winter. The plan pursued by the growers for market in this district is a very simple one, and consists in merely scratching the ground after it has been cleared of the early Potatoes, and sowing the seeds broadcast, and then harrowing the ground to bury them. When large enough the plants are thinned-out to from 6 to 9 inches apart, and to prevent the attacks of the Turnip fly it is often necessary to scatter a quantity of spent hops from the brewery over the crop. As the ground is usually very dry at this time it is a good plan to give it a thorough watering before sowing the seeds. It is best to sow Lettuce seeds, Radish, and any small salad under a north wall. In whatever position they may be sown, watering in very dry weather is absolutely necessary. See that the Celery crops are carefully attended to that have been planted-out early. Want of water will cause many of the plants to bolt. More trenches must be planted for succession.

VINERIES.

We have been able to clear the Vines of the early crops of Grapes, and were glad to give the leaves a thorough cleansing with a garden engine, applying the water with considerable force, but taking care not to injure the leaves. The ground is also well watered if necessary; not the outside border, but the inside generally becomes too dry before the crops are gathered. In the late houses it is easy to perceive which berries are likely to be small and stoneless, and it is a good plan to remove them at once. Shanked berries are also better removed as soon as they are perceived. A very little attention to the small details of Vine culture makes all the difference between a houseful of bunches with even-sized berries and branches regularly arranged, and a house where the bunches are uneven and the branches disorderly. We have recently gone over the late houses and pinched back the lateral growths, taking care that each bunch is securely fastened to the wires by means of a stout strip of matting. It would be well to again remark on the importance of judicious ventilation, and in arid weather see that the atmo-

sphere is kept sufficiently moist by sprinkling water on the paths, borders, and walls of the house.

CUCUMBERS AND MELONS.

During the next six months no artificial heat is required for these, whether they are cultivated in pits and the Vines trained over the surface of the ground, or grown in span or half-span houses. Those who have the means to do so (and we question whether it would not pay better even for those who wish to grow for market) should grow their plants in a house where they can walk underneath them, as so much more enjoyment is derived from their culture in this way; and those who have to attend to the plants find it so convenient to water, syringe, train, and regulate the growths; and one great advantage gained by training to a trellis overhead is that the under sides of the leaves can be washed with the syringe, and that is where spider attacks them. Excellent Cucumbers and Melons can be produced in ordinary garden frames, nor is it necessary to trouble about the linings of fermenting material. The best frame Cucumbers we have ever seen grown received no more attention as regards watering than to have two pots of water placed inside the frame, and after having been exposed to the heat of the frame through the day, each light received about three gallons, applied through the rose of a water-pot. This was done every day through the summer months, and the shoots were thinned-out as required, and the young growths pegged down once a week. In houses the usual routine of work is syringing and damping three or four times a-day and closing early in the afternoon. When the Melons approach the ripening stage syringing must be discontinued, but we do not allow the soil in which the plants are growing to become dusty dry.

PLANT STOVE.

In treating of our own "doings" reference must always be made to the more choice species of hardwooded plants, the most select of "foliage" plants, and Orchids. Many who have small stoves cannot grow such, and others may prefer Gloxinias, Achimenes, Gesneras, &c. The earliest of the two first-named will now be approaching their resting period, and must have more air admitted to them and be kept rather drier at the roots. A small house, or even a garden frame, would be as suitable a place as any in which to place the plants, where they could receive the right treatment. Other plants for succession must be grown in a warmer, closer, moister atmosphere, but we do not approve of syringing the leaves.

Celosias.—The pyramid-branched variety is the most useful for decorative purposes, and the cut sprays are very suitable for placing in vases. The culture of these plants is very simple. They are annually raised from seeds. The plants must be grown-on rapidly by potting in rich loam and a little leaf soil. They must be kept in heat and daily syringed to prevent the attacks of red spider. Under good management the plants may be grown 3 or 4 feet high and as much across in one season. Then we have the ordinary Cockscomb (*Celosia cristata*), plants of which are highly useful for decorative purposes. These are usually grown in garden frames over a bed of fermenting manure. When the plants are shifted into the pots in which it is intended they are to perfect their flowers bottom heat is not necessary, and the frames should be well ventilated, the object being to prevent the stems from becoming drawn up. Red spider is also very fond of feasting on the under-sides of the leaves, and wherever this pest goes a blight follows it, and the leaves speedily become yellow. The plants when well grown have a bold appearance when arranged with other plants on the greenhouse stage.

All young plants of such subjects as Bouvardia, Thysacanthus, Euphorbia, Eranthemum, Begonia, &c., which were raised from cuttings early in the season must now be grown-on without any check. They must be potted before the roots are too much matted to the sides of the pots, and it depends much upon the size it is intended to grow the plants as to the size of the pots that ought to be used, as some of the above grow very rapidly. Bouvardias are well known to be so useful at the dreariest season of the year, their delicate snow-white blush and red flowers lighting up the gloom of dreary November and December, that few persons would be without them. Our plants have just been turned out of doors in the company of *Poinsettia pulcherrima*. The young shoots push out vigorously, and must be regularly stopped until the plants are sufficiently large and of a compact habit. The plants must be regularly syringed to prevent them from becoming infested with the inevitable spider. The other plants named should be grown near the glass, and be shaded from fierce sun.

Climbing plants are apt to straggle far from the bounds allotted to them at this season, and they must be restrained by a free use of the knife. At the same time see that the leaves are washed free from dirt, bag, and scale.—J. DOUGLAS.

TRADE CATALOGUE RECEIVED.

W. Dobbie, 62, Preston Street, Faversham.—List of Variegated and Bedding Geraniums.

TO CORRESPONDENTS.

* * All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

BOOKS (*Grains*).—"The Cottage Gardener's Dictionary" explains the terms employed.

APPLYING APHIS MIXTURE TO ROSES (*B.*).—Apply the aphis mixture with a brush, when out of bloom syringe with soft soap. Your trees must be much out of health, or the aphides would not be very numerous. In the fall of the year lift the plants and root-prune them. Give them some new soil if possible; if not, trench deep or move the soil altogether. Spread the exhausted soil on the lawn or on the pasture land.—WYLD SAVAGE.

ROSE BUDS (*Tyro*).—They are advertised in our columns by Mr. Cannell, Swanley, Kent. A budding knife is indispensable, as a common knife must tear the bark and injure the wood.

GRUBS ON ASPARAGUS (*X.*, *An Amateur Gardener*).—If the specimen sent is a fair sample of the condition of your Asparagus the beds will be greatly injured, if not ruined, unless you promptly destroy the enemy, which is the grub of *Crioceris asparagi*. We should syringe the Asparagus and then dust it with lime. We should at the same time sprinkle salt on the surface of the beds, making it quite white. We should further like you to try the experiment of syringing with paraffin in different degrees of solution, and to inform us of the result. We think you will thus be able to kill the grubs without injuring the Asparagus.

GARDEN PLAN (*Prima*).—Curves are more graceful than straight lines. We do not think the walks too numerous.

FERNS (*A Constant Reader*).—The specimens were not numbered.

FRAGRANT ROSE (*H. C.*).—We consider Duke of Edinburgh the best bright scarlet and fragrant Hardy Perpetual Rose.

HIGHEST STRAWBERRY (*H. U.*).—We knew an Oscar Strawberry weigh 5½ ozs., but it was a monstrosity.

PEAR TREE BLIGHTED (*Mr. Welch*).—The border probably requires to be drained and manured. The Currant bushes should be dusted with flowers of sulphur, which will not injure the fruit if the sulphur is syringed off a few days after it has been applied.

VARIOUS (*L. H. Bromley*).—The Vine border requires manuring. The insects are red spiders.

PEACH TREES BLIGHTED (*J. F. N.*).—We presume the trees have been attacked by the Peach aphis, and as the leaves have fallen off it is a serious case—indeed we never knew of such a case. Probably the Gishurst compound was too strong and caused the leaves to drop off. Whatever was the cause, a large proportion of the wood will die. This you must cut out, and it may even be necessary to cut the trees quite back and force them to start from near the base. You must destroy the aphis (as is so often recommended in the "Doings of the Week") in its early stages.

GROWING STRAWBERRIES FOR MARKET (*J. H. P.*).—We advise you to have the ground trenched 2 feet deep, working in at the same time a good supply of rich manure. If you fancy the deep trenching is too expensive the ground ought at least to be double-dug—that is, dig out a spit and then go over the same ground and throw out another, working in some good manure at the same time. Plant as early as you can, and if the plants are strong and can be put out at once you will have some fruit next year. Plant in rows 2 feet apart and 18 inches between the plants. The best sorts to grow are Keens' Seedling, President, Sir Charles Napier, and British Queen. You may add a limited quantity of Duc de Magenta, James Veitch, and Frogmore Late Pine.

GLOXINIAS AFTER FLOWERING (*H. Bullock*).—The plants should be kept in an airy house, but not be too cool. At present they may be placed on shelves near the glass in a pit or greenhouse. When the leaves become yellow water must be withheld entirely. Place the pots on their sides in a cool stove under the stage until it is time to start them in the early spring.

MANAGEMENT OF PELARGONIUMS (*Idem*).—We presume that you do not mean the zonals, but the varieties usually termed show Pelargoniums. They ought to be cut down now, but you must allow the soil to become very dry first, and do not give any water for a day or two after cutting down; this is to prevent bleeding. When the plants have grown an inch they must be repotted. At all times the plants should be near the glass and be freely exposed to light and air.

ARRANGING INTERIOR OF HOUSE FOR STOVE PLANTS (*J. D.*).—The shelf all round the house is too narrow for the growth and display of specimens; the width should be 3 feet, which could be gained by making the pathway 3 feet instead of 4 feet wide. The shelves should be of flags or slate, having a slate edging about 3 inches deep. The side shelves should be about 6 inches lower than the wall plate of the side lights—about 2 feet 6 inches from the floor. Upon the shelves 1½ to 2 inches' thickness of gravel may be placed, rejecting the small particles passing a quarter-inch sieve, and only using gravel which has passed through a three-quarter-inch sieve; upon the gravel the pots can be placed. The appearance is good, and water passes freely from the pots, and a supply of moisture by evaporation is also ensured. If climbers are required for the roof, planted out in borders, apertures must be left in the shelves. Ours have an opening for each rafter, the shelving being supported by stone pillars, and the border for the climbers having a stone curbing, the border being the width of the side shelves—viz., 3 feet. The piping for top heat may be beneath the side shelves. We should have six rows of 4-inch pipes all around the house—three flows and the same number of returns, and the whole of the flow pipes troughed for holding water for evaporation. The centre of the house we should dispose of as a bed 2 feet 6 inches high, with side walls 14 inches thick to a height of 15 inches, with longitudinal walls inside for the support of the tank or chamber cover-

ing; 4½-inch walls built in cement will answer, two walls being required or more according to the width of the covers, the walls not being taken to the ends within 2 feet where the pipes enter for heating the bed. You will have to decide whether you will have a tank or a hot-air chamber. In the latter case two pipes are taken along each compartment of the bed, it being presumed that you have two walls and three compartments in the bed, the pipes being fixed about 4 inches beneath the covers, so that six rows of pipes will be required for bottom heat. If this method be followed the side walls of the pit need not be more than 9 inches thick. All that is needed is to put on the covers, resting them on the side and internal supporting walls, and then take the side walls up to a height of 2 feet 6 inches; 4½-inch thickness is as good as thicker if cement is used for the joints. When the covers are put on a hot-air chamber, the covers being 3 inches thick, less if slate be used, we have 1 foot left for plunging material, the best that can be used being cocoa refuse. In case of a tank being desired, and it certainly is preferable, the outside walls must be 14 inches, and the floor of the bed must be laid with bricks upon a hard bottom, run with cement after laying it, and the side walls being plastered with cement to the height of the cover's base. Six rows of pipes are laid, and water is admitted by a tap from them until they are covered with water not more than an inch deep. Provision must be made in the side wall, so as to get at the tap by a man hole so as to keep the tank replenished with water as required. The covers are then put on, the joints fitting closely; no pointing is needed—indeed, they must be left open, and we have a tank with 1-foot space above it for plunging material. By inserting 4-inch pipes, three rows at a yard apart, through the covers into the tank, letting them rise just above the plunging material, each being supplied with a hard wood plug, the atmosphere is furnished with moisture as may be desirable. An open tank or chamber with a stage over is of no value as bottom heat, and such heat is absolutely essential for the superior cultivation of some stove plants.

MANURING WATERCRESS (*Eastleach*).—Of the "blight" we can say nothing in the absence of a specimen and particulars; but as to manuring, the best that can be applied is well-decomposed cow dung, the first dressing being given in a week from planting, about half a bushel to the rod (30½ square yards), it being disposed over the plants and pressed down with a rather heavy board having a handle fixed in it obliquely, and after each cutting the plants are manured with well-decayed cow dung, spreading it over the naked plants and pressing well down with the rammer above alluded to. September to November is a good time to make fresh beds to come in in spring, and May and June for cutting in August. The shoots should always be cut and not picked, as picking is found to be injurious to the plants.

GERANIUM LEAVES SPOTTED (*Novice*).—The spotting probably arises from defective ventilation.

SILVER SAND (*Ten-years Subscriber*).—It is very good, and well suited for potting purposes.

ROSE BUDS DEFORMED (*Atkinson*).—The injury may be caused by too sudden transitions of temperature, such as being exposed to bright sunshine and at night to cold winds.

TROPEOLUX SPECIOSUM.—Mr. James Weston, Tanfield Lodge, Croydon, wishes to obtain a plant.

PRESERVING GREEN PEAS (*A. Z.*).—Pick them when full grown, shell them, dry them gently but thoroughly, and then store them in canvas bag in a dry place. When required for use soak them in water for a few hours until plumped-up, and then boil them. The following mode has been reported to us by a person well qualified to judge of such matters as being very successful:—Carefully shell the peas, then put them in tin canisters, not too large; put in a small piece of alum, about the size of a horsebean, to a pint of peas. When the canister is full of peas fill up the interstices with water, and solder on the lid perfectly air-tight, and boil the canister for about twenty minutes; then remove them to a cool place, and they will be found in January but little inferior to fresh newly gathered peas.

FUNGI (*C. Princep*).—Both are dangerous.

GREEN FLY IN CUCUMBER FRAME (*W. R.*).—Syringe with tobacco water, and then with plain water.

NAMES OF PLANTS (*A. H.*).—*Jasminum Sambac flore-pleno*. (*Mrs. L.*).—*Astrantia major*. (*J. P.*).—All appear to be forms of *Biota* (*Thuja*) *orientalis*. (*Ponica*).—1, *Biota* (*Thuja*) *orientalis*; 2, *Lastrea spinulosa*; 3, Apparently the same. (*D. Gurney*).—*Araxia albens* (*Phytanhus albens*, *Bot. Mag.*, t. 5201), native of Brazil. (*G. O. S.*).—*Sphaeralcea acerifolia*, with lower leaves unusually divided.

POULTRY, BEE, AND PIGEON CHRONICLE.

VISIT TO MR. H. M. MAYNARD'S PIGEONS,

HOLMWOD, RYDE, ISLE OF WIGHT.

PART 2.

BEFORE passing through the door to visit the first series of Pigeon pens I am shown the food which the birds eat, and it is of the soundest kind. I may also observe that Mr. Maynard has recently bought the stock of Carriers lately belonging to Mr. Harding of Fareham, a well-known breeder and exhibitor. As usual now-a-days these birds did not become Mr. Maynard's without an outlay of several hundred pounds. The outer world frequently imagines that the best Pigeon is only a bird which will cost a few shillings, but a champion Pigeon now, if of a high-class variety, costs many dozen pounds; and no one can dream of becoming a successful exhibitor without a considerable capital and a shrewd business head, combined with thorough knowledge of Pigeon points. With such qualifications he may with experience become a successful exhibitor without pecuniary loss, though not even every successful fancier can become in his class what Mr. Maynard has become in his special class—Carriers, of which he is the prince of amateurs.

The garden, a flower garden, which I now enter wears an old-fashioned aspect—walled, spacious, square, with an infinite number of beds edged with box, and in one corner of its south

side is the conservatory connected with the house. A warm garden, one which the chilliest invalid could creep about in whenever a gleam of sunshine broke out on even a winter's day; a warm, sunny, cosy garden, made to catch and retain heat. Now along part of the south and west sides of this garden are arranged Pigeon pens, each with nesting place along the wall, and fairly roomy exercise and feeding place joining on, running still along the wall, not coming out into the garden. The Pigeon pens, of which there are many, may be likened in position to a series of greenhouses, each divided into two compartments—the nesting room dark, the flight room light with a wire front. Thus lengthwise, not endwise, they meet the garden and abut a path down which we walk to look into the pens; to the right hand the pens, to the left the garden. But the reader will say the rain must drift into the broad wirework of the somewhat wide-fronted pens, and the sharp winds will bring rousp and all manner of troubles to the delicate high-class birds. These contingencies are avoided by a clever contrivance: a verandah is thrown over the path, glazed halfway down from the top of the side fronting the garden, but entirely open on the lower part. Hence no rain can drift in, and yet there is abundance of air-coming, as fresh air should come, from the lower part. There are fifteen houses in all, including others out of the garden, and a stock of upwards of four hundred Pigeons. Somewhat central in the garden and by itself stands another pen; this contains Barbs, Carriers, and Jacobins, some of the second named having belonged to Mr. Harding of Fareham. The kind of nesting box which Mr. Maynard adopts and finds most useful is most simple and inexpensive—a little deal box 13 inches long by 11 wide; in front a hole for entrance, just the same as to a common wall locker—thus, *Q*. Then the whole of the back is a sliding door, through which you put in and take out for examination the nest pan, which just about fits the box. Thus the entrance of the bird itself is not interfered with—no putting the hand in in front of the bird, and a Pigeon always seems to be jealous of any hand entering its home, and pecks sharply at the fingers and gives blows with its wing, whereas enter from behind and the bird is not disturbed. These boxes are set about in different places, many on the floor, others on shelves; and they form nice, separate, detached, snug nurseries for the Pigeons, and the top being flat is a perching place for the cock, while the hen sits within on her eggs or young during night. I should recommend these boxes, particularly for shy and pugnacious Pigeons such as Carriers, as fewer eggs would be broken and fewer fights take place than with any other plan known to me.

Before going the round of the flower-garden pens I am invited to look at one placed somewhat in the middle of the garden. Here I found Carriers, chiefly Duns; among them an old Dun hen and a young Dun, with fine necks and good colour. There were two Jacobins, a class which Mr. Maynard is working up, especially White Jacobins.

Coming to the pens by the wall I find in one the champion Barb hen, and others nearly her equal; then fine Black Carriers, then among other choice birds Black Barb cock, first and cup at Birmingham, and a magnificent Dun cock, and so one went on repeating the sight of Carriers and Barbs, then some Fantails, then more Carriers and Barbs.

At the back of the flower garden I find some new houses recently built by Mr. Maynard, and upon the more general plan of a breeding and roosting part, and a flight loft in front 12 feet by 9. These contained White Jacobins (now being improved by fanciers), the bull-eyed and the small-frilled being weeded out, but too often the Turbit head or, more correctly speaking, the Foreign Owl head, is apparent in a certain flatness or dent which takes off from the beauty of the bird. In another of these new pens are Fantails, some Scotch of Mr. Huie's strain. All the prize birds are now Scotch and English combined. The large, heavy, flat-tailed English bird now is disappearing. Mr. Maynard's are both, so are Mr. Serjeantson's. This is another proof that the union of England and Scotland is a mutual benefit, for the Scotch birds gain in tail by the English cross.

In these pens Mr. Maynard has a few Blue Carriers. This variety seems to be most troublesome to manage, for the best Carriers are smoky in plumage, while the best coloured are Dragoon-like and old Horseman-like in shape. With these birds, and of course many Barbs, are a very few white Pouters, also some Red Jacobins, their colour being very rich, possibly from the shady nature of the pens, they being stoutly rooted over, with no light save at the sides. But yet two more lofts, and a climb I had to get to them—up perpendicular ladders. In the first, a large granary-like building, I find Carriers only; in splendid plumage, as they have an outlet to the wired-in roof—the plan well-known as Mr. Wallace's of Glasgow. These birds were very numerous and about two years of age, and in a good strain Carriers of that age are fully adult; unlike Barbs, who require four or five years. I saw no finer sight at Holmwood than the rows—row after row of these birds, which had been especially kept in for me to see. There they sat on the rafters crossing the building, looking the perfection of Carrier beauty—sleek, bright, clean, and above all things grown up, but not yet grown

old, at which period of life they degenerate greatly—beak opening, eye dull; in fact, in one word old, and in old age bird-beauty utterly goes. Last lot of all—a small one over a stable, where I find a wonderful old hen Carrier, a grand bird, but, "old Master Shallow, without doubt she is old." She may, this Dun hen, have a young one or two this year, but "tis the last time of asking," and "no more, no more—oh! never more."

After lunch another peep at the more choice Pigeons, then a stroll about the 30 acres of ground in Mr. Maynard's hands. I came in different parts of the grounds upon splendid lots of Silver-pencilled Hamburg fowls and chickens, among the latter the best I have this year seen, though I have seen a large number of Hamburgs of this variety. How neat, tidy, and clean the Silver-pencilled look when kept in a country place such as Holmwood. I remember the very same birds many years ago when called "Dutch everyday layers," while the Golden-pencilled, or rather Golden-spangled, were known as Pheasant Fowls. The Golden-pencilled I do not remember. Then further on were the Rabbits, the variety kept being the Belgian Hare. So what with Pigeons and Wire-haired Terriers, a Dandy Dimont, a prize Cat, fowls of various kinds, and Rabbits—pets abound at Holmwood. Having seen much and admired much, and made pleasant acquaintances, it is time to return to catch the last boat for Stokes Bay; so I drive down, all down hill now, with the silvery Solent glimmering before me, and part from my Holmwood friends with regret.—WILTSHIRE RECTOR.

HECKMONDWIKE SHOW OF POULTRY, &c.

THIS was held on the 14th inst. in connection with the newly-formed Agricultural Society. The schedule was a moderate one and the returns pretty good for a start. The pens were from Sheffield and were in the open air, the entries being near three hundred; but unfortunately the day proved very showery, and many of the birds were wetted.

In poultry the *Spanish* and *Polish* were about the best of the large varieties; but *Bantams* were good in every class, the first winners in all cases being about perfect, notably the Duckwings, to which two specials were awarded; and the Blacks, which were smaller than usual and very correct. In chickens of any variety first were Buff Cochins of grand quality; second good Light Brahmas; and third Gold-spangled Hamburgs, in which pen the pullet was a gem. Ducks and Geese were good but few in number.

Pigeons were a strong lot, but the unfortunate mistake of having them mostly in pairs caused considerable confusion and prevented many from entering. Pouters and Carriers were, however, single birds, and these were very good. The Dun Carrier cock to which the first prize was awarded was in grand form and good all round; second a Black, wanting only in age. Hens, first a young Black of high quality, strong in beak and general build; and second a Dun. In Pouters the cocks were best, some of the best hens being very dirty. Tumblers.—First and special for the best pen in the Show a pair of Almonds, good all round; second an exquisite pair of Yellow Mottles. Long-faces.—First Black Balts and second Red Mottles; a good class. Dragoons good in both sexes; first in both being grand Yellows; second in cocks a Blue and in hens a Silver. Several others good, but many too soft and fleshy in eye. Jacobins a grand lot, and all Reds that were noticed. Turbits mostly Yellows, and very good in head properties. Antwerps were moderate as a class but good as regards the winners. Owls.—First White African and second Blue English. Barbs a very good class, but some too far gone and nearly closed in eye; but the winner's frill in condition and good in eye and skull, all Blacks. Variety class.—First Mottled Trumpeters, second Red Magpies, and two thirds respectively to Grey Frillbacks and Pigmies.

Rabbits few in entries. The winners in Lop-ears were pretty good, the Angoras and Silver-Greys grand, but the Dutch only moderate. In the Variety class first was a good Belgian Hare not in the best order; second a large common-looking Rabbit, which some will no doubt call a Belgian Hare, but in fine order.

POULTRY.—GAME.—Black Red.—1, C. H. Mason. Brown Red.—1, W. Schofield. 2, J. W. Thornton. 3, W. Rudd. Duckwings, Blue or Grey.—1, H. G. Mason. 2, W. Rudd. 3, W. J. Mason. Any other variety.—1, R. Walker. 2, J. E. Crofts. 3, W. J. Mason. COCHINS.—Buff.—1, E. Sidgwick. 2 and 3, W. Mitchell. Any other variety.—1, D. Key. 2, T. W. Terry. BRAHMAS.—1, H. Beldon. 2, J. Rawnsley. DORINGS.—1, H. Beldon. HAMBURGERS.—Gold and Silver-spangled.—1 and 3, H. Beldon. 2, J. Rawnsley. Gold and Silver-pencilled.—1, H. Beldon. 2, J. Rawnsley. Black.—1, Hobson & Robinson. 2, H. Beldon. 3, J. Rawnsley. vhc. C. Sidgwick. J. S. Wilson. SPANISH.—1 and 3, J. Powell. 2, M. J. Thresh. SELLING CLASS.—1, A. & W. H. Silvester. 2, J. E. Crofts. 3, H. Beldon. ANY BREED.—Cock.—1, H. Beldon. 2 and 3, A. & W. H. Silvester. Hen.—1, H. Beldon. 2, Wood & Walker. 3, L. Bowker. FRENCH.—2, H. Beldon. BANTAMS.—Game, Black and Brown Reds.—1, A. Sugden. 2, F. Holt. 3, S. Firth. Game, Any other variety.—1 and 2, F. Holt. 3, I. Goodall. Black and White.—1, J. F. Crowther. 2, H. Beldon. 3, Illingworth & Sheard. Any other variety.—1, J. F. Crowther. 2, H. Beldon. ANY VARIETY.—Chickens.—1, C. Sidgwick. 2, E. W. & H. King. 3, T. Dean. EXTRA PRIZES.—1, R. Walker. 2, Holt (2). Ducks.—Dylesburgs.—1, J. Newton. 2, J. A. Newton. 3, J. E. Crofts. Any other variety.—1 and 2, A. & W. H. Silvester. GEES.—1, H. Beldon. 2, J. F. Crowther. PIGEONS.—CARRIERS.—Cock.—1, H. Yardley. 2, E. Mawson. Hen.—1, E. Horner. 2, G. E. Beaumont. POUTERS.—Cock.—1, J. E. Crofts. 2, E. Horner. Hen.—1, J. E. Crofts. 2, J. Tomlinson. TUMBLERS.—Short-faced.—1, H. Yardley.

2, E. Mawson. *Long-faced*.—1 and 2, W. Lund. *FANTAILS*.—1, H. Beldon. 2, E. Horner. *DRAGONS*.—*Cock*.—1 and 2, R. Woods. *who*, E. Horner. *Hens*.—1 and 2, R. Woods. *who*, J. Ratcliffe. *JACOBIANS*.—1, T. Holt. 2, E. Horner. *TURBITS*.—1, T. Holt. 2, E. Horner. *who*, H. Beldon. *ANTWERPS*.—*Short-faced*.—1, W. F. Entwistle. *Medium-faced*.—1 and 2, W. F. Entwistle. *Long-faced*.—1, E. Rawnsley. 2, J. Robertshaw. *Young*.—1 and 2, W. F. Entwistle. *OWLS*.—1, A. & W. H. Silvester. 2, S. Brier. *BARBS*.—1, E. Mawson. 2, M. J. Thresh. *ANY OTHER VARIETY*.—1, E. Horner. 2, J. E. Croft. 3, R. Wilson. A. & W. H. Silvester. *who*, Founds & Chapel. *SELLING CLASS*.—1, E. Horner. 2, G. E. Beaumont. 3, A. Roberts. *who*, A. Roberts. A. & W. H. Silvester. *EXTRA PRIZES*.—1, H. Yardley.

RABBITS.—*LOP-EARED*.—*Buck or Doe*.—1, Mrs. Roberts. 2, J. Nicholls. *ANGORA*.—*Buck or Doe*.—1 and 2, Mrs. R. Murgatroyd. *HIMALAYAN*.—*Buck or Doe*.—1, J. Robertshaw. 2, W. Whitterton. *SILVER HAIR*.—*Buck or Doe*.—1, S. Ball. 2, J. Robertshaw. *DUTCH*.—*Buck or Doe*.—1, S. Ball. 2, J. Robertshaw. *COMMON*.—*Buck or Doe*.—1 and 2, J. Oddy. *ANY OTHER VARIETY*.—*Buck or Doe*.—1, J. Ramsshaw. 2, A. Atkinson.

JUDGES.—Messrs. Dixon and Hutton.

SNATH SHOW OF POULTRY, &c.

THE annual Show was held in the magnificent and beautifully wooded Park at Snath on Thursday last. The poultry and Pigeons were well protected in a spacious marquee, and well attended to. Game headed the list, but with few exceptions these were poor; but *Dorkings* a capital lot, as also the *Brahmas*. *Hamburgs* good, but few in numbers; and *Spanish* only three, but very good. *Polish* were, first Silver and second Gold, the former winning the cup for the best pen in the Show. With the exception of the winners the Game *Bantams* were but poor. In the Bantam variety first were Blacks and second Silvers.

Pigeons were a better lot than the poultry, both as regards numbers and quality, and the birds generally in good order. *Carriers*.—First a grand Dun cock, and second a Black. *Pouters*.—First a Black hen that won the painting also for the best bird in the section, second a well-known Blue cock; both in capital show form. *Jacobins*.—Red won first, a grand bird; second losing in little but mane, of which it had little. *Owls*.—First Silver and second Blue. *Barbs*.—First and cup Black, and second Red. In *Maggies* were some good ones; both the winners. *Reds*. In *Dragons* a Grizzle was placed first, but we preferred the same gentleman's Silver for that position. *Antwerps*.—First Red and second Silver Dun; both *Short-faces*. In the Variety class first was a White African Owl, and second a good Nun.

There were some *Rabbits*, but nothing of any note.

POULTRY.—*GAME*.—*Black-breasted or Brown Red*.—1, G. Carter. 2, F. Sales. *Any other variety*.—1, F. Sales. 2, J. E. Crofts. *DORKINGS*.—1, J. Walker. 2, J. White. *COCHIN-CHINA*.—1, J. Walker. 2, W. Aaron. *BRAHMAS*.—1, J. Walker. 2, H. Beldon. *HAMBURGERS*.—*Golden-spangled*.—1, H. Beldon. 2, J. Rawnsley. *Silver-spangled*.—1, Fawcett & Anderson. 2, J. Rawnsley. *H. Beldon*. *Golden-pencilled*.—1, H. Beldon. 2, J. Rawnsley. *Silver-pencilled*.—1 and 2, J. Rawnsley. *Black*.—1, H. Beldon. 2, J. Rawnsley. *SPANISH*.—1 and 2, J. Powell. *POLANDS*.—Cup and 2, H. Beldon. *ANY OTHER VARIETY*.—1, T. Addey. 2, J. D. Booth. *BANTAMS*.—*Game*.—1, 2, and *who*, W. F. Entwistle. *Any other variety*.—1, H. Beldon. 2, J. W. Crowther. *BARNDORF FOWLS*.—1, E. Hill. 2, H. Thompson. *GUINIA FOWLS*.—1, H. Thompson. 2, J. H. Rockett. *SELLING CLASS*.—*Price not to exceed 3s*.—1, F. Sales. 2, T. Addey. *Price not to exceed 50s*.—1, Holmes & Destner. *DUCKS*.—1, J. Walker. 2, J. P. Carver. *Any variety*.—1 and 2, J. Walker. *TURKEYS*.—1, J. Walker. 2, T. P. Carver. *GEESSE*.—1, H. Beldon. 2, J. Walker.

PIGEONS.—*CARRIERS*.—*Cock or Hen*.—1, H. Yardley. 2, F. Seaton. *POUTERS*.—*Cock or Hen*.—1 and Painting. C. Wood. 2, J. E. Crofts. *JACOBIANS*.—*Cock or Hen*.—1, T. Holt. 2, T. S. Stephenson. *TRUMPETERS*.—*Cock or Hen*.—1, E. A. Thompson. 2, J. E. Croft. *TURBITS*.—*Cock or Hen*.—1, H. R. Tenney. 2, J. E. Spence. *H. Yardley*. *FANTAILS*.—*Cock or Hen*.—1, H. R. Tenney. 2, J. E. Spence. *TURBITS*.—*Cock or Hen*.—1, G. Sadler. 2, R. Wood. *OWLS*.—*Cock or Hen*.—1 and 2, J. W. Stansfield. *BARBS*.—*Cock or Hen*.—1, Cup, and 2, S. Dyson. *MAGPIE*.—*Cock or Hen*.—1, R. Wood. 2, J. E. Crofts. *DRAGONS*.—*Cock or Hen*.—1, R. Wood. 2, H. Yardley. *ANTWERPS*.—*Cock or Hen*.—1 and 2, W. F. Entwistle. *ANY OTHER VARIETY*.—*Cock or Hen*.—1, H. Yardley. 2, F. Seaton. *SELLING CLASS*.—*Cock or Hen*.—*Price not to exceed 25s*.—1, F. Seaton. 2, R. Wood. *Price not to exceed 5s*.—1, S. Dyson. 2, H. Yardley. *ANY VARIETY*.—*Buck or Doe*.—1, O. Stephenson. 2, J. Armstrong.

JUDGES.—*Poultry*: Mr. J. Crosland, Wakefield; Mr. J. Dixon, North Park, Clayton, Bradford. *Pigeons and Rabbits*: Mr. J. Hawley, Gillington, Bradford; Mr. J. Crosland.

TEACHING CANARIES TO SING.

WHETHER for the purpose of tutoring young Canaries under choice songsters, or teaching them to sing with the aid of a flageolet or bird organ, one important point is to remove those to be taught from birds of indifferent song; or out of the hearing entirely of all birds if the young are to receive instruction from an instrument.

Now-a-days the chief aim of Canary fanciers appears to be the breeding and study of fine-plumed birds for exhibition purposes; but this was not so much the case with fanciers of past ages, who studied the cultivation of song more than is done by fanciers of the present period, at least in this country.

The name of Hervieux (a writer of a treatise on Canaries) is not unknown to many readers of our Journal, and from him we quote at what time and in what manner Canary birds may be put-up to be taught with a flageolet.

"It is a certain truth that, next to the Nightingale, the Canary bird sings best and has the strongest voice of any little bird. When young they easily learn what they are taught, as airs and tunes on the flageolet. For my part I prefer them before the Nightingale, because they are much harder to rear than Canary birds. . . . The Nightingale, after all the pains taken in feeding and rearing, generally sings but one short season of the

year, whereas our Canary birds are continually warbling at all times. For these reasons I think the Canary ought to be preferred notwithstanding the Nightingale's notes are somewhat more harmonious."

As proof of the hatred Mr. Hervieux entertained against the barbarous practices of depriving the birds of their vision and enclosing them in stifled prisons he says, "As for the time when a Canary bird is to be put into a separate cage in order to teach him, that is commonly eight or ten days after he feeds alone, and not, as many do, who take him out the first day they see he feeds alone, without allowing him time to gather strength. They unmercifully shut him up in a box—a sort of so-called cage all shut up with boards, with some little holes that they may not be quite stifled for want of breath. That poor little creature, being thus scarce able to breathe, and being deprived of proper air which strengthens the body almost as much as food, grows melancholy and pines away, so that it often dies in a few days in its dismal prison. If you desire to succeed better in that point you must observe this method.

"A fortnight at soonest after your Canary bird has been taken from the hen, if you perceive he begins to warble, which is a good sign that he is a cock and in good health, part him from the rest and put him into a cage covered with a very thin transparent linen cloth for the first eight days. Put him into a room distant from all other birds whatsoever, so that he may never hear any of their wild notes, and then play to him upon a little flageolet; the notes whereof not too high, for if your flageolet is too loud your Canary, who will not fail to follow the same tone when he has learnt the air, and will repeat it several times a day, will so dry up his lungs that it will cause him to grow lean and die in a few days.

"At the end of a fortnight take away the linen cloth and supply it with a piece of thick green or red serge, and leave him still in the same place till he perfectly learns what you teach him. Some Canary birds are more apt to learn than others, for some are perfect in two months and others not in six; but you must have patience when you resolve to teach them anything, without it nothing can be done. When you give him his food, which must be enough for two days at least, it must be done by candlelight, that he may not be distracted, but may learn what he is taught the sooner.

"As for the tunes, he must be taught only one fine prelude and a choice air. When they are taught more they are apt to confound them, and being taught too much they often know nothing perfect, their memory becoming overburdened, so that they know not what they sing. Besides, their distemper of moulting, which is once a-year [or should be if kept in a steady and regular temperature], and lasts above two months, diverts them, so that they do not sing, and consequently easily forget the tunes they have been taught with so much trouble.

"Do not follow the notion of those who think that the many lessons they give their Canaries every day improves them the more; they tire themselves and only make the birds uneasy. Five or six lessons a-day are sufficient for a Canary, though he be ever so little disposed to learn; besides, the trouble would much outweigh the pleasure if a man were to be continually about his Canary birds. You must, therefore, give them but two lessons in the morning when you rise, another about noon, and the same before bedtime. The morning and evening lessons benefit the birds most, because at those times when all is still, the birds being less diverted, better retain what is taught them. The tunes taught them must be repeated nine or ten times at every lesson, and those same airs must be played running without repeating the first part of them twice, and the conclusion in the same manner, as is usually done in concerts or other playing. A grey Canary bird of a good breed is more apt to learn from a flageolet than any other sort of Canary. You must not pretend to teach two Canary birds in the same room, much less in the same cage, as many have attempted to do. If that be done it must be only for a time—that is, as soon as one of the two begins to take the tune, then they must be immediately parted at such a distance that they may not hear one another, because they will do nothing but distract each other, and it would be all lost time to them and to him who teaches the birds."

In the book from which the above is quoted the prelude and air spoken of are given.—G. J. BARNESBY.

APIARIAN EXPERIENCES IN 1877.

It may be interesting to some of your apiarian novices to follow the fortunes of an old bee-keeper, and therefore I shall narrate here the fortunes of my apiary thus far in the present season.

Let me say by way of preface that I do not go in for keeping bees so much with a view to make if possible £70 a year, or indeed anything in the way of profit beyond supplying the wants of my household and those of a few friends, and so I am content to keep but few hives.

This year opened with fair prospects of success. One hive in an oblong box of good size in a bee house was exceptionally

strong both in population and supplies. It had a young half-breed Italian queen of last year breeding as well-marked workers as many an imported queen. This hive was carrying pollen more or less all the winter and very largely in February, so much so that the bees kept up a summer-like humming throughout that month; nor did the hive cease working like some others in the miserably cold weather of March and April. For all that the hive did not swarm till the 31st of May, at least a month later than it would have swarmed in ordinarily seasonable weather. The swarm, however, was so large that in the course of three weeks with the fine weather of early June it had completely filled its box—a fac-simile of the parent hive, and constructed seven combs full of honey, but not all sealed up, in a super. Since then there has been absolutely nothing harvested nor any more comb made. The honey is fast disappearing from all the open cells, and the bees have shrunk in numbers apparently to about half what they appeared before; and yet a quantity of brood must have been hatching every day since the 21st of June, for I saw quantities of sealed brood in several combs; moreover there is hardly a drone to be seen in the hive nor in any other part of my apiary save where I have young queens coming on or just winged. I am writing on the 6th of July, in the midst of thundery weather and with quantities of white clover in bloom in our rich pastures, yet the impoverishment of the hives continues everywhere. Nor can the weather be complained of, since it has been for the most part bright and hot, though not so hot as in the early part of June. It seems to me that flowers do not generally bear honey in any quantity until the plants that produce them have reached their full prime. This occurs generally in pretty even distribution, all the plants reaching that prime pretty well together. Then, if the weather is propitious, often quite suddenly, the secretion of honey begins, and continues in the case of that particular plant for several weeks at a time. The forwardness or lateness of the season has much to do with the time when this secretion of honey commences and continues.

Hereabouts we have but two such periods of honey supply in the year. I believe this is the common experience in all parts of England where heather is not found; and even where heather abounds the duality of the honey seasons usually prevails, for in this case there is commonly a scarcity of apple and other fruit blossoms, and not much honey is collected in May. The clover is late this year—fully three weeks or even a month behind time; I am therefore not without hopes that we may get a fair yield of honey yet. I have known it come in quantities so late as the first week in August.

To return to my apiary. The stock which gave me the swarm of May 31st threw off a cast fully equal in size to the original swarm on the 9th of June. This was hived in a box of the same character and size, not bar-framed, and was located in the old stock's place. To my surprise the latter, though moved to no great distance in my garden, and consequently losing almost every fully-grown bee, recovered population so rapidly that it is now as strong a stock as any in my apiary. I must, however, state that this stock is the one referred to in my communication at page 23 of the current volume of this Journal, into which the queen of a neighbouring hive is supposed to have entered when returning home after an abortive attempt to swarm. Certainly a large portion of the returning swarm entered it and remained there.

It will thus be seen that my best stock has multiplied itself to three, all equally strong in population or nearly so. The swarm and old stock are well supplied with comb and honey, while the cast is already three parts full of comb, although sharing the general stagnation of the apiary at the present moment. The swarm and cast too have both supers partially filled by them with comb and honey, but it remains to be seen what my honey harvest will be. As I am shortly leaving home for a month it will be some time before I can report progress. Meanwhile let us hope for continuous fine weather suitable for the ingathering.—B. & W.

OUR LETTER BOX.

At the Staffordshire Poultry Show, advertised to-day, we see several classes not previously patronised; among them are Black Cochins and Leghorns any colour. We believe every care will be taken of the birds, and to return them immediately after the Show.

FRENCH EGGS.—The declared value of eggs imported this year to the 30th ult. was £1,494,885, against £510,563 in the same period last year.

VARIOUS (T. Hill).—We cannot publish Cowan's honey extractor. Write to the special rose nurseries for those you need. The lectures on bees have not been published.

BEES CASTING OUT WHITE DRONES (Novice).—The grubs are young drones that have been born from their cells before arriving at maturity. In unfavourable seasons such as the present one bees not unfrequently cast out imperfect drones, and their doing so may be viewed either as a precautionary measure against dreaded poverty and starvation, or as an indication that their hopes and anticipations of future success are somewhat checked and blighted by unfavourable weather. Shall we trace the conduct of bees in the destruction of brood to their wisdom or thought? Premeditation there must have been, followed by united action. Hives that are full enough for swarming and prepared to some extent for swarming are often discouraged by a change of weather, and begin to cast out unhatched brood and sometimes

destroy perfect drones. Such hives are on the confines of poverty, and abandon for the time being the idea of swarming. On a return of fine weather the hopes of the bees are once more excited, all their combs become filled with brood, and preparations for swarming again take place. This may happen more than once in a season unfavourable for honey-gathering if artificial feeding be not resorted to. In cold seasons, and also at the end of all seasons, we find that bees kill and cast out drones which are in such times useless members of their communities. It is doubtless an instinct of their economy to do so, and may be viewed as a wise provision of nature. This season one of my hives began to cast out white drones a few days after it had yielded a first swarm—a most unusual occurrence. The swarm of our correspondent which was obtained on the 10th of June and housed in a Nutt hive has probably not filled its hive with combs, and therefore is not ready for supering or entering a side compartment of the hive. In this part of Cheshire the season has been worse for bees than any we have had for many years. The appearance of white drones outside our hives in the middle of July fore-shadow that our sugar bees may be as much needed as our honey jars in the autumn of 1877.—A. PETTIGREW.

RABBITS (Lackfield).—Buy our Rabbit manual. You can have it free by post if you enclose eight postage stamps.

DRESSING RABBIT SKINS (Small Boy).—Take the skin as fresh as possible, and having mixed a sufficient quantity of salt and water till it will bear an egg, saturate it with alum. Put the skin into this bloodwarm, and let it lie and soak twenty-four hours; then take it out, and having tacked it upon a board (the fur inwards) scrape the skin, and a thin membrane will come off; then, having warmed up the pickle again, put the skin into it a second time, and let it remain five hours more, after which take it out and nail it upon a board to dry (fur inwards), and then rub it with pumicestone and whitening. Hare and other skins may be prepared in the same way. They are always in best condition for preparing in the winter.

REMARKS.

- 11th.—Dull and stormlike all the morning and till past noon, after that fine and pleasant all day.
 12th.—Fine but rather overcast at 9 A.M. and till noon; the after part of the day very bright, with fine evening and night.
 13th.—Beautifully bright with nice breeze all day, but rain at 10.40 P.M.
 14th.—Wet at 9 A.M., fine before noon, but showery after, and a very wet night.
 15th.—Rain in early morning, fair at 9 A.M.; sunshine and showers alternately all day, the rain at times very heavy; thunder about 2 P.M.
 16th.—Fine early, but rain began before 9 A.M., and continued all day and night except in the evening.
 17th.—Dull, grey, showery day throughout.
 Mean barometer much lower than during the preceding week. The mean 9 A.M. temperature about 2° and the night temperature 9° higher; but the sun temperature is 9° less, the rain was both frequent and heavy, and in the early part of the week thunder was heard almost daily.—G. J. SYMONS.

COVENT GARDEN MARKET.—JULY 18.

THE late rains have damaged the outdoor fruit very much, most of it arriving in very bad condition, and causing prices to fall. There is still a good demand for first-class goods, such as Peaches, Nectarines, Pines, Melons, and the higher qualities of Grapes. Trade steady.

From observations taken near London during forty-three years, the average day temperature of the week is 75.2°; and its night temperature 50.3°.

CONDITION AND QUALITY OF MELONS.

MELONS were generally very poor last year in the south; they were small in size and indifferent in quality. I had the opportunity of tasting many fruits exhibited—perhaps nearly all—at the metropolitan shows, and very few really first-class Melons were submitted to the judges.

Two of the best fruits of the year—good in size, handsome in appearance, and of excellent quality, were Eastnor Castle, green flesh, exhibited at the Royal Botanic Society's Show, and Blankney Hero, exhibited at the Alexandra Palace. Reid's Netted was excellent in most instances, as was the good old variety Turner's Golden Gem; nor must I omit mentioning a fruit of A. F. Barron, exhibited by Mr. Pithers at the Richmond Show, which was certainly one of the best Melons of the year. Several good fruits of Victory of Bath were also exhibited, while others were indifferent in quality.

What was the cause of the low standard of quality of Melons last year? and what is the reason that the same variety is so variable in quality even when exhibited by the same cultivator?

These two questions may be worthy of a little consideration at the present time. I can only attribute the general unsatisfactory condition of so many fruits to excessive heat and its consequence a deficiency of moisture, also to the somewhat marked prevalence of red spider. My reason for attributing the flavourless character of many fruits to extreme heat and drought is in a measure derived from the fact that Melons in the northern counties, where the heat was less intense, were, as a rule, greatly superior to Melons in the south last year. I have observed also during several years of practice that it is a mistake to adopt a fixed rule in withholding water from Melons when they are approaching the ripening stage. That is a very old custom which was adopted by our forefathers, and it is surprising our old customs—simply because they are old—cling to the inhabitants of our old country. Our forefathers may have been right in the practice which they adopted, and I believe they were right; but—a very important “but” is that—they grew Melons on dung beds, while many are now grown over hot-water pipes.

I was told by a gentleman the other day that the standard quality of his Melons was better half a century ago than it is now. That is a strange comment on the “progress of the age,” and somewhat interferes with the “great improvements” which have been recorded during every consecutive year of the present generation. I am inclined to believe that the gentleman alluded to was right, first because he is an excellent judge of Melons and is most observant in comparing the quality of garden produce, and secondly because I never remember having tasted better Melons than the old Beechwoods of thirty and the Bromham Halls of more than twenty years ago.

The best Melon supply that I am cognisant of was

produced in a nobleman's garden about the period last alluded to, and where Bromham Hall was almost exclusively grown. I mean by that, that many large frames were devoted to that variety, and the fruit of it was counted by hundreds, while other varieties were only grown “for trial”—a plant of a sort, and not one was at that time found to equal Bromham Hall. Never do I remember hearing a single complaint of inferior quality when that good old sort was sent in for dessert; and never do I remember taking fruit to either local or the great metropolitan exhibitions which did not win first honours.

The Melons, as remarked, were grown in dung-heated frames; a few were grown in a house heated with hot water, but the prize Melons were always cut from the frames. The gardener—for I was only an “under-strapper” then—was an excellent cultivator of fruit and plants generally and of Melons particularly. I never knew a gardener to give so much water to Melons as he did, and he continued it until the very day of cutting the fruit. Not a red spider was permitted on the foliage; the frames were kept too moist and the foliage too stout in texture for this pest gaining a footing, and every leaf was fully exposed to the light. There was not the slightest semblance of overcrowding of the foliage, and pruning as it is generally understood was not adopted. Every afternoon when watering, every shoot that was not wanted was picked-off with the finger and thumb before it was an inch in length; thus no check was given to the plants and no useless growth permitted in the frames. Overcropping was particularly guarded against, and the foliage when the fruit was cut was as green and healthy as at any period during the season; indeed the early plants (the first crop was ripe at the end of May) always produced two crops. The plants were frequently watered and their foliage sprinkled with perfectly clear soot water. To that I attributed their extreme health, the rich dark clean foliage, and the absence of red spider.

The grower of those Melons was an excellent judge as to the exact time for cutting the fruit and placing it on the table. Many times have I seen a fruit rejected as being “too ripe”—a day too old. Its perfume has been rich, but when cut the general quality of the fruit has almost invariably not been perfect. I think there is a great deal in placing a Melon on the table just at the right time; and I think it possible that they are often placed there and sent to exhibitions a day too late. Unless that is so, how can we account for the great difference in quality of Melons of the same variety? I could submit several instances of the variations of Melons on the point of quality, but two will suffice. Last year Mr. Frisby exhibited a Melon named Cocoa-nut before the Fruit Committee of the Royal Horticultural Society, but as then staged the fruit was comparatively flavourless, and the Committee were not justified in awarding it their approval. Subsequently a fruit of the same variety was exhibited at the Alexandra Palace, and was awarded a first-class certificate, Mr. Douglas—who is also a member of the Fruit Committee of the Royal Horti-

cultural Society—having been one of the judges. That excellent Melon was purchased by Messrs. James Carter & Co., and was named Blankney Hero. Another instance of a Melon showing extreme variation in quality was afforded by my own experience. I had a very fine and highly perfumed fruit of Bromham Hall which I intended to win first honours at an exhibition. I was annoyed by an important dinner party occurring the night previous to the show, and the very best Melon was demanded on the table. Emphasis was laid on the "very best," because the Melons, as a rule, had not quite given satisfaction that year. I felt compelled, therefore, to send in my fine exhibition fruit, and was more annoyed than ever to receive the verdict of "not good" with more than half the Melon which was handed to me the next morning. To the verdict I was obliged to agree, for certainly the fruit was "not good." It occurred to me that it must have been over-ripe—a day too old, and therefore I cut from the same plant another fruit which I considered not fully ripe, but which required one or two more days to perfect, and took it to the show. It was awarded the first prize unanimously. Its perfume before being cut was not remarkable, indeed scarcely noticeable, but its quality proved extremely rich. I then felt satisfied that I had fallen into the habit that year of keeping the Melons a day or two too long before I considered them in the best condition. I changed my mode of judging them, cutting them and sending them to table earlier, even before the aroma appeared to be fully developed, and not one fruit was afterwards found fault with during the whole of the season. With many fruits all the care in culture had been rendered nugatory by an error of judgment as to the time of sending it to table. I think it possible that similar errors are made by others in exhibiting Melons; they keep them as they think until the fruit is just at its best, and in doing so keep it a day too long.

The subject may be worth mentioning now, and also the practice, which has proved successful, of not "drying off" the plants during the ripening period. Keeping the foliage clean, fresh, and healthy until after the fruit was cut, and staging it just before its full aroma appeared to be developed, resulted in some of the best Melons being produced and the best prizes won with them which have come under my notice during a tolerably long period of practice.

The best Melons which have been exhibited in the south this year have been Victory of Bath and Excelsior by Mr. Gilbert, Reid's Netted and Cox's Golden Gem by Mr. Miles at the Royal Botanic; and Bloxholm Hall by Mr. Crane, and Eastnor Castle by Mr. Clifford at the Bickley (West Kent) Shows.—J. W.

SWEET-SCENTED CLIMBING PLANTS.

It is early morning, the time 5.50. I have just opened a window of my sitting-room, letting-in the fresh morning air laden with a perfume so rich that in a few minutes it pervades the whole of the house, and one sniffs it with a gusto which must be something akin to that of the bees, already at work busily sucking honey from the flowers whence it comes, and which are so truly worthy of their old familiar title of Honeysuckle. As I inhale the delicious perfume the thought arises, Is not this worth telling the readers of the Journal about? But then it has already been done indirectly more than once; and yet how seldom does one meet with the plant in full perfection! so I beg of all who desire to have fragrant climbing plants to read what I shall write and to do as I shall ask.

I think it would not be incorrect were I to assert that my Honeysuckle bears away the palm for sweetness, not only from other sorts of its own species, but from all other plants. "What!" you exclaim, "have you forgotten the Violets about which Mr. Abbey wrote so pleasantly and usefully the other day, the Mignonette, Lily of the Valley, Stephanotis, and Jasmine?" No, I have not forgotten them, I grow and like them all; but not one of them is equal to my Honeysuckle, which gives off waves of scent continuously—scent so rich and yet so delicate withal that it never cloy the palate, never offends and oppresses like a Lilium or Magnolia.

The scientific appellation of my Honeysuckle is *Lonicera flexuosa*. It has very long flexible growth thickly clothed with foliage of the deepest shade of green, most of which it retains throughout the winter; and for a long time in summer its young growth is laden with thousands of deep red, slender, tubular flowers, giving forth the fragrance which now fills my house. Its growth is wonderfully strong, stout, and free, running in a

few seasons to the top of a high building, and at the same time spreading-out so thickly and well laterally that it clothes whatever surfaces it is trained upon perfectly in every part—a property of no mean value, for many of our best climbers are often bare of foliage for several feet from the ground. When its flowers fade in summer it is my custom to prune it, cutting off all the pendant breast shoots, which induces a fresh growth that in a mild autumn bursts freely into flower.

It answers perfectly and grows with equal rapidity upon every aspect, and once established in good soil its roots require no further care—no annual dressings of manure or soakings of sewage like the Rose. We have here, then, a plant of great excellence, flourishing in all soils that are tolerably fertile, upon all aspects, and in all situations; spreading its trailing growth over masses of rock as freely as it mounts upward upon the sides of a lofty building, clothed with foliage throughout the year, and in summer bearing a profusion of flowers unrivalled for sweetness. It is so readily propagated and so easily managed that you may procure a strong plant of it in a pot from any nurseryman for 1s. Its growth is so flexible and free, and bears pruning so well, that it may be allowed to mingle with Tea Roses or other especial pets, and yet readily be kept within bounds.

In *L. brachypoda* my favourite *flexuosa* has no mean rival, each bearing the closest resemblance to the other in habit and freedom of growth, abundance of flowers, fragrance, and time of flowering, both being now in full perfection; but *L. brachypoda* is as distinct as possible from *L. flexuosa* in point of colour, its flowers being white and pale yellow, and with foliage and branches of a light green hue, in charming contrast to the deep colours of *L. flexuosa*, so that they may be planted together with the happiest effect. It would not surprise me if preference were most generally given to *L. brachypoda*, for a large plant of it when in full bloom presents a singularly elegant and striking appearance.

L. grata, also very sweet-scented and now just past its best, is altogether a bolder type of Honeysuckle. Its growth is stouter, and the foliage and flower clusters proportionately larger; but it altogether lacks the graceful refinement of *L. flexuosa* and *L. brachypoda*, for, apart from an air of coarseness, its growth is rigid and erect—a real advantage when the plant is well placed and suffered to ramble, for then it puts forth wonderfully robust shoots, bearing huge clusters of flowers which tell well upon a pillar or high-up on the wall of a lofty building.

L. fragrantissima, which comes into flower in early spring, is so sweet that I must not omit to name it here. It is a most distinct variety, with a stout, erect, shrub-like growth, and handsome evergreen foliage.

The perfume of a Honeysuckle prompted me to write this note. To the Honeysuckles precedence has been given as due, but I must not omit mention of such sweet-scented climbers as we have in the Wistaria, Jasmines, Chimonanthus, and Clematis flammula; the last-named plant has rightly been described as being as fragrant as a Hawthorn.—EDWARD LUCKHURST.

THE AIR-TIGHT VINERY.

In answer to the request of "W. L. A." as to construction of an air-tight vinery, I beg to inform him that the important points are—that the building should run direct north and south, and that the sides should be at such an angle as to cause the rays of the sun to glance off during the scorching hours of the day. The building may be of any length. As it costs 10s. per foot run, £50 goes a long way, and if the soil be well prepared half this sum may be obtained by selling the Grapes yearly, as they come in early; and even after they are ripe they may be kept hanging some time to insure a good market, as the building is air-tight, and quicklime placed in small heaps absorbs all moisture.

The roots also can be kept dry at this time by placing over them brown paper steeped in the thin kind of creosote (reams of paper may be soaked at a time). The mode of placing this waterproof covering on the border is in this way:—You must have a net (also steeped in this creosote, which makes it lasting), which is to be stretched tightly over the border by means of strong cord tied to the sides. By wooden stumps it can be fixed in a slanting position to throw off rain. The paper is placed evenly on this net, and another net is stretched over it to keep it in its place. This will last for several years.

But to proceed with the building. The sides should be 8 feet in height, the ground floor 7 feet wide, the roof 3 feet

wide. This may be flat, or rather 1 inch higher on one side; it may be of two pieces of glass abutting in the centre. The woodwork should be grooved and the glass well puttied-in; the uprights joining the sides are to be grooved and puttied. I cannot recollect a single square of glass having been broken for eight or nine years. There is a door at each end on the south side: the end is always whitewashed. This prevents red spider, which always used to attack the last Vine in the S.W. corner. It has never done so since, showing that whitewashing prevents red spider. The whole forms an avenue of Grapes, and has a very pretty effect.—OBSERVER.

GARDEN ROSES.

OF all the floral embellishments of the garden the Rose is the greatest favourite and is the most generally cultivated, for it is grown in almost every garden, from that of the palace to the home-plot of the humble cottager. Eulogium were it attempted must fail to do justice to the charms of the queen of flowers. Poets of all nations have sung its praises, but have not found language sufficiently emblematic of its beauty, for its allurements are ever increasing. The Rose affords beauty in its fairest, brightest, and richest aspect, with a fragrance that is delightful; in fact, it possesses a combination of qualities which renders it superior to every other flower.

Profuse displays are most aimed at in gardens, a luxurious profusion of flower, filling the eye with colour and the atmosphere with fragrance. I have a good recollection of what a blaze of beauty our rosaries were for a time when summer Roses were in their glory: the immensity of bloom produced was something wonderful. Yet we may have a mass of colour produced by blooms which are individually inferior. Some summer Roses are indeed very beautiful—perfect in form, very lovely, and worth a place in gardens, but a majority are only suited for semi-cultivation. Have as many as there is room for at the outer boundary of the rosery, employing the strong growers with the climbing class for clothing poles, buildings, &c., requiring ornamentation; but as Roses for the garden their day is past, if for no other reason than their short period of flowering.

Summer Roses being "out of the race," and as everyone "pats" the winning horse, I will pass on to the description of Rose most in request in gardens. In a Rose for the garden we must have a variety excelling in form, size, substance of petal, and continuity of flowering, fragrance being an additional recommendation. These qualities we have in autumnal Roses. For a Rose garden a sheltered situation should be chosen, for though Roses like sun and air the foliage and flowers suffer in exposed positions from winds. A low screen of shrubs or the hardier and commoner kinds of Roses are suitable for shelter. The ground should be well drained and trenched as deeply as the good soil will permit, working-in good manure liberally. There is nothing like a good foundation. Nothing beats good sound rather strong loam for Roses, which may be trenched 2 or 3 feet deep; but it is little use bringing-up the "brash" that underlies many shallow soils, though it is desirable to loosen it to some extent and apply a good dressing of manure. Very strong loams will need little beyond manure, whilst shallow light soils will be improved by applications of strong loams or even marl.

In choice of plants dwarfs are preferable to standards, especially in exposed situations. A few standards may be desirable to give variety of form and height, but as a rule standards do not look well in a rosery, and are not so satisfactory as dwarfs. Dwarfs upon the Manetti stock are most suitable worked low, so that the whole of the stock may be buried beneath the soil, the junction of stock and scion being about 3 inches beneath the surface soil. I will omit details of planting, as these may be more appropriately alluded to as the autumn approaches, but I may mention a few points which should be attended to during the summer.

The "worm i' the bud" will need to be seen to, than which there is no better remedy than hand-picking and squeezing the folded-up leaves, and insects must be kept under by syringing the bushes with a solution of soft soap, 2 ozs. to the gallon of water. The foliage is also much refreshed by syringing overhead in the evening of hot days. Water and liquid manure can hardly be given too freely in parching weather, especially to Roses in shallow soils. Mulching with short material is also good, inasmuch as it retards evaporation, keeping the soil more uniformly cool and moist. We have only to cut away the flowered shoots to the first good leaf beneath the

flower after the petals are shed, and stop any gross shoot not flowering at the height of the blooming or bloomed shoots so as to keep the heads compact, and we may rely upon a continuity of flowers until frost.

It is a common idea that Roses in beds or masses should have the shoots pegged down, to which there can be no objection when profusion and not perfection of blooms is sought. It is a practice that answers well for sloping banks, the shoots being pegged down much in the way of Laurels, and the young growths kept within bounds by timely removal of such as grow too long and mar the effect. For pegging down the plants should have the shoots encouraged the first year, allowing them to grow at will, the object being to secure as many long shoots as possible, and as near as may be of uniform strength. After they have grown a foot or more in length the shoots should be secured by pegs in an oblique direction, but not bringing them close down, all weak shoots being cut clean away, seeking to impart as much vigour as possible to the primary shoots. The shoots, after the ground has been duly manured and dug, may be pegged close down. No pruning is required beyond cutting off the unripe ends of the shoots. Every eye will give its flower or truss of flowers, and the effect is certainly superb; yet the blooms are not worth much as compared with those grown on bushes. Such an unnatural mode of growing the Rose as pegging it down only serves a special purpose, and is not to be advised when good blooms are wanted. It is mentioned because every phase of Rose culture should be noticed in a journal having so many "Rose readers."

Hybrid Perpetuals, as before stated, are most suitable for gardens and make splendid masses, it being advisable to employ but one kind in a mass or to keep the lines distinct by having varieties that will contrast in colour. The following in their respective colours are good for masses, have well-formed flowers, producing them freely, and have good constitutions. They are good alike for garden or house decoration.

Dark Crimson.—Charles Lefebvre, Prince Camille de Rohan, Fisher Holmes, Lord Macaulay, Louis Van Houtte, Duc de Rohan, Eugène Appert, Pierre Notting, Charlotte Corday, Le Rhone, and Maréchal Vaillant.

Red or Crimson.—François I., Général Jacqueminot, Alfred Colomb, Beauty of Waltham, Dupuy-Jamain, General Von Moltke, Madame Victor Verdier, Sénateur Vaisse, Thomas Mills, Prince de Portia, and Comtesse d'Oxford.

Rose and Pink.—La Ville de St. Denis, John Hopper, François Michelon, Baronne Prevost, Comtesse de Chabillant, Anna Alexieff, Abel Grand, Annie Laxton, Auguste Mie, Baronne de Rothschild, Berthe Baron, Capitaine Christy, Jules Margottin, La France, Lyonnaise, Madame Clert, and Edouard Morren.

White or Blush.—Boule de Neige, Madame Lacharme, and Mademoiselle Bonnaire.

Fragrant Hybrid Perpetuals.—Baronne Louise Uxkull, rose; Bessie Johnson, blush; Claude Levet, crimson; Duchess of Edinburgh, pink; François Courtin, crimson; Madame Eugène Appert, rosy pink; Madame Ferdinand Jamin, rosy carmine; Madame Vidot; Mademoiselle Marguerite Dombrain, rose; Marie Thérèse, rose; William Jesse, rose; Oxonian, rose; and Queen Eleanor, rose. Of the newer kinds Rev. J.B. M. Camm and Miss Hassard have sweet-scented flowers.

The next Rose that I will name is the Damask Perpetual, Crimson Perpetual, or Rose du Roi, crimson, than which there is no finer and sweeter for cutting from in late summer. A large bed of this and Mogador or Crimson Superb ought to be in every garden. They require liberal treatment—that of Hybrid Perpetuals.

In *Perpetual Moss Roses* we have Souper et Notting, rose and fragrant; and Mrs. W. Paul, rose, one of the freest blooming of this family, while few are prettier in the bud state than the Winter Perpetual. All require high culture and close pruning.

Of *Bourbons* worthy of mention—Armosa, pink; Baron Gonella, deep rose; Queen of the Bourbons, fawn-coloured salmon and sweet, especially late in the season; Sir Joseph Paxton, rose shaded crimson, are all good and free-flowering. They require a sheltered situation, liberal treatment, and close pruning. Louise Margottin, pale rose or blush, is one of the most hardy.

China Roses.—These make good beds, especially Aubert, red; Ducher, white; Fabvier, crimson; Cramoisie Supérieure, deep crimson; Louis Philippe, crimson; and Mrs. Bosanquet, flesh. They are best upon their own roots, and if well mulched will come away strongly from the base if the shoots above ground

are injured by frost. Few Roses are finer in the bud than the old Blush or common China, a bed of which is worth a place in every garden.

Tea-scented Roses.—These are unfortunately tender, but if grown as dwarfs and mulched in winter, some dry litter being placed over the shoots in severe weather, will succeed in sheltered situations; that good old Rose Gloire de Dijon is however, very hardy. They require a good rich soil, light rather than heavy, and moderate pruning. Abricoté, Anna Olivier, Madame Caroline Kuster, Madame de St. Joseph, Madame Joseph Halphen, Mlle. Thérèse, Monsieur Henry Bennet, and Paul Plantier are free-flowering. Madame François Jamin, Madame Docteur Jutte, Louise de Savoie, and Madame Chaveret have great fragrance, as have Madame Schultz and Triomphe de Rennes in the Noisettes, Rêve d'Or being the hardest of that family.

I would mention few autumnals which are pretty in the bud. Niphetos (Noisette) Safrano, Sombreuil, and Perle des Jardins. In Tea-scented or Noisettes Gloire de Rosamène (Bourbon), Perpetual White Moss, Marie Boissée, Madame Freeman, and Marquise de Ligneris (Hybrid Perpetuale).

In *Summer Roses* (though old associations may keep them alive their day is past) only a few will have note—viz., Provence (Cabbage), desirable for its fragrance; Crested for its beautiful buds, De Meaux for its earliness, Spong for its smallness and usefulness, and Unique white. Good treatment is required and close pruning.

Moss Roses are indispensable if only for buds, Céline being superb. The common Moss is very beautiful, Lanei and Marie de Blois being very mossy, and White Bath. Close pruning and very liberal treatment is needed to bring them to perfection.

Of Hybrid Chinas Blairi No. 2, and Hybrid Bourbons Coupe d'Hébé and Paul Ricaut are the best.

I have only to add of Austrian Briars Harrisoni, which requires to have the weak shoots thinned out, pruning those left about one-third of their length, keeping the soil liberally manured. All the Roses named are valuable for garden decoration and for affording "bushels of flowers" for cutting, many of them also affording "exhibition blooms."—G. ABBEY.

THE HARDY FRUIT CROP IN NORTH WILTS.

ONE almost feels inclined to put the above in the form of a question, thus: "What crop of hardy fruits is there in North Wilts?" and add as answer, "There is not any," in imitation of the question and answer, "What are the manners of the inhabitants of such an island?" "They have not any." In truth the answer would be literally correct as to Pears. On twelve trees I have counted only two Pears. Ten had not even one. Plums (standard Orleans), not one; Damson trees, not one; Coe's Golden Drop, just a few; Bullaces, none; wall Plums, six on three trees, the six being Coe's Golden Drop again. Apples with me an utter failure, the only tree giving anything like a crop being a Hawthornden half-standard; pyramids a crop only, and that a poor one, on one tree, and that a Golden Pippin. I visited a grand walled garden recently, grand in results rather than show, and which I have visited regularly for upwards of twenty years, and always found a great abundance of fruit. This garden is long and narrow, and by its walls and narrowness protected from much wind; and the frost too being what the gardeners here call "broke by the walls." The whole of one side I found cropless, whether the trees were wall, pyramid, or standard. The other side there is a very little. Apples fair, but the old Hawthornden stands out in grand singularity by producing an abundant crop. Pears there were next to none; sometimes on one branch, possibly sheltered by another tree, there would be a few. As to orchards, the scarcity of Apples is considerable, not that, like Pears, there is no crop at all. The orchard which I have seen being at this time most prolific is one which happens to have a belt of forest trees around it, consequently its trees are sheltered from the frost and blighting winds by the larger trees. There are exceptions to the scarcity: thus, Strawberries are most abundant, Currants of all kinds are plentiful, Walnut trees are in some cases bent earthwards with the weight of the "nuts."

I hear of bad news as to fruit in and near Bath. My readers will remember that it is a district favoured for fruit trees, and fruit on them. Pleasantly writes, or, alas! wrote, Charles Kingsley of this place and neighbourhood as follows:—"Now here we are at Bath station, and here are the handsome fruit women" (not so handsome now as when Kingsley wrote—Roses

still, but overblown) "waiting for you to buy; and oh! what Strawberries and Cherries! Yes, all this valley is very rich, and very sheltered too, and very warm, for the soft southwestern air sweeps up it from the Bristol Channel, so the slopes are covered with fruit orchards, as you will see as you get out of the station." Very pretty description this, but I am told that as to Pears one of the greatest cultivators of pyramids near Bath has literally none at all.

So that this fruit district, and I am only about ten miles from Bath, has utterly failed as to Pear crop this season; still my belief is that all is carried on in a system of compensation. As the farmer, who was condoled with on the death of his mother-in-law, replied, "Ah! poor old lady; very sad, but then I have got in my hay uncommonly well." So I say the fruit will be short this year—nay is; but what a capital year for growth it will be! What wood is being made on many a tree that was nearly killed with bearing! Yes, a growing year this year; a fruiting year next, I trust.—WILTSHIRE RECTOR.

MULCH.

MATERIAL applied to the surface of the ground around trees as a sort of coating is termed mulch. Mulching is resorted to for various purposes. 1, To retain moisture. This is one of the prime uses of all mulching and always to be considered. 2, To shade the ground during summer, so as to prevent excessive heating by the sunshine. It is said that heating the roots of trees above 70° is injurious, a statement we fully credit. Where the sun shines directly on clean dark-coloured soil it is often heated to a much higher degree, and that to the depth of several inches in all probability. With the thermometer at 95° in the shade we found it to rise to 120° very quickly in the sunshine, a heat altogether incompatible with healthful growth of a tree in this climate, or proper retention of moisture. 3, To retain the tilth of the soil, to prevent baking and hardening of the surface. A hard surface, a compact soil, without porosity or aëration, is not congenial to plant growth. That mulching prevents hardening of the surface is well known. 4, To render the soil fertile and to retain fertility. This arises from the decomposition of the material used, from the resulting porosity and prevention of evaporation. 5, To prevent extreme freezing of the ground, and to protect against sudden freezing and thawing. Anything to protect from extremes or sudden changes of temperature we consider beneficial, but more particularly the extremes of cold. 6, To retain frost around the roots to prevent too early a start in the spring. Many mulch with this object in view, but our observation and experience are that it will make no practical difference. When warm weather comes the buds will start in spite of mulching, even though the ground be frozen below. The idea that sap flows with warm weather during winter in an Apple tree is erroneous. Fruit trees are not like Maple trees in this respect. The sap of fruit trees does not circulate till spring comes. During winter, when thawed, there is a resupplying of the moisture that has been dried out during preceding freezing, dry weather—something we deem quite essential to the successful wintering of fruit trees.

Concerning the time of applying mulch practice differs. Regard must be had to circumstances and what effect is desired. 1, During winter and autumn after growth is over. This of course would be preparation for the next season. Its application at this time will give different effects, and like that of any other time may have a different relation to different farmwork, &c. 2, In the spring when growth begins. Applied at this time it would have an effect not generally desirable in most fruits—viz., retaining excess of moisture and frost too long in the ground. 3, During the growing season. Suppose the surface of the ground around the Apple tree to be given clean culture during May and first part of June, allowing the sunshine to warm the soil and start the tree into vigorous growth. About the middle of June the weather becomes quite warm and drought often sets in. This we deem the most favourable of all times for applying mulch, as it will protect against the extremes of summer heat and drought, and will not have been applied so soon as to prevent the benefits of spring sunshine.

Concerning material for mulching, practice also differs. 1, Tree leaves, Nature's mulching, probably are superior to any other, but these are not always attainable. 2, Animal manure, with more or less of barnyard litter, &c. The application of animal manures to fruit trees has always been more or less a mooted question. Our observation and experience in

this climate are that it is very injurious, and sooner or later will result in the total loss of the trees to which it is applied. 3, Earth, such as muck, loam, &c. This is often an important modifier, and useful over coarse light litter to prevent its being scattered by the winds. 4, Vegetable manure in the form of half-rotten straw, fresh-cut weeds, Clover, &c. Doubtless the most practical and appropriate of any material. 5, Wood-chips, sawdust, tan bark, &c. If you want to have your trees infested with borers, &c., use old chips and you will not wait long. Our observation and experience are adverse to the use of chips on that account, and because they seem to mould and mildew the soil below. Concerning tan bark we have no experience, but think none of these on decaying would give such congenial fertility as vegetable manures. 6, Mineral fertilisers, such as lime, ashes, &c.; not so much as a mulching proper, however, as a sort of modifier and accompaniment of the foregoing. Lime is especially useful in fruitage, and for assisting in giving health and ripening-up each summer's growth. Ashes act more like animal manures in having a stimulating effect. When mulching is applied, care should be taken to protect against vermin, both insects and rodents, for many such may harbour in the material used. To protect against mice, remove the mulch close to the trunk of the tree, and bank with clean earth a foot high.—A. L. HATCH (in *Transactions Wis. Horticultural Society*).

THE AQUARIUM ROSE SHOW.

THERE is something very sad to us rosarians about the last Rose show of the season. Though we are in the height of our short English summer, though the Teas are still in full bloom, and in the north of England at least the Hybrid Perpetuals have still to blossom, yet to know that another twelve months must elapse before we shall exhibit our pets again is, to say the least, by no means an exhilarating prospect. So it is with mixed feelings of sadness and delight that I sit down to write a few lines about the Aquarium Rose Show—sadness caused by the above reflection, and delight inspired by the vivid memory of the beauties exhibited that day.

It was indeed the last show, but certainly it was not the least. Perhaps in numbers the Exhibition might be called a small one, but if small it was like a Duke of Wellington, good. There was no class for seventy-two or forty-eight trebles. The Aquarium people were both generous and merciful. They, no doubt rightly, considered that the 18th of July was a late fixture for the great nurserymen, and that seventy-two would be a difficult number for any to stage well, and so they made forty-eight singles the highest class and reduced the trebles to twenty-four; but they by no means reduced to any extent the prizes, and offered nearly as much (within £1 indeed) money for forty-eight singles and twenty-four trebles as other exhibitions offer for the higher numbers. The same generosity was extended to the amateurs, who, instead of being asked to stage forty-eight and twenty-four trebles, were let off easily with twenty-four singles and twelve trebles. The consequence was that the stands throughout the Show were very good and the exhibitors much pleased, while the Judges' duties were proportionately lessened. The arrangements also were very good: there was no hitch of any kind, and a very pleasant day was spent. The list of the prizewinners was given last week, so I need only make some cursory remarks on Roses and exhibitors such as appear, according to my judgment, to be most worthy of recording.

As I had prophesied, the fixture suited Mr. Cranston better than any other London show, and he showed his grand form by winning both the leading classes and by almost carrying off the class for twenty-four singles; but even this Show was a little too early for him, and I can well believe that if the Agricultural Hall Company were to give a Rose show—(why don't they?)—during the next fortnight Mr. Cranston would show in much finer form than he did on Wednesday. His blooms were very large and fine, and some of the novelties in the stands exceedingly good. Abel Carrière again came to the front, also La Rosière and Marguerite Brasseur. Too much cannot be said in favour of these Roses. They are grand additions to the dark class. Abel Carrière has not only colour very like Pierre Notting or Jean Cherpin, but also grand form. If you were to take a perfect bloom of Centifolia Rosea as shown by Mr. George Paul, and by some magical means change its colour to a dark velvety purple, you would have a good imitation of Abel Carrière. La Rosière is an improved (or will, I think, prove so) Prince Camille de Rohan, and Marguerite Brasseur is a second edition of Charles Lefebvre. Perhaps it has not quite the substance of the latter, but then it is a new Rose and there cannot be a large stock of it, and it would indeed be giving a high character to any Rose to say that it equalled Charles Lefebvre, the grandest of Roses; still in time it may, and now with the above exception I don't see that, as shown this year by Messrs. Corp and Cranston, it is

far behind. Mr. Cant was a good second, but his Roses gave evidence that his blooming season was, alas! near the end. This gentleman and also Mr. Paul travelled all night from Scotland in order to be present, leaving their men to cut their blooms, and turning up just in time to put the finishing touches to their stands and, to the great delight of the leading amateurs, to judge.

There were six stands of twenty-four trebles, all good and worthy of prizes; in fact, I do not remember ever judging such good trebles. When such a grower as Mr. George Paul is left out in the cold, as he was in this class, the general excellence of the stands may be imagined. Mr. Cranston was easy first, but Mr. Turner and Mr. Cant ran so close together that it was a most difficult matter to decide who was the better. Mr. Turner would, however, have more easily won second honours if he had not put in a very coarse treble of Souvenir de Malmaison and also a bad one of Sir Garnet Wolseley. I hope that good grower will forgive me for presuming to give a hint on such a matter, but over and over again have I seen his splendid stands spoilt by one or two trebles of coarse, large, overblown blooms. Several times I have noticed Paul Neron in his back row, and Antoine Mouton, and (as to-day), Souvenir de Malmaison, and the effect upon the mind of a judge who puts form before size is most deleterious to the exhibitor. Mr. Turner had some splendid trebles, particularly Duke of Edinburgh and Niphetos. Mr. Cant's were smaller but fresher and cleaner, but I have the great pleasure of knowing that all our awards satisfied that "good Judge and good fellow."

In the class for twenty-four and twelve Mr. Corp of Exeter well maintained his Clifton reputation. I cannot too highly praise his stands, they were beautiful. To my mind Mr. Corp more nearly approaches Mr. Baker (Hercules), in the general excellence of his stands than any nurseryman I know. Colour and freshness and good form are the prevailing features of the stands of both, and in many instances the same blooms are to be found which are pre-eminently good. Mr. Corp also had splendid Teas, and I cannot help thinking that in a few years he will attain a very high position. May I take this opportunity of informing your readers that this grower has an immense quantity of Teas on the seedling Briar for sale, and I am informed that they are very good plants? As I for one know the great difficulty of procuring Teas, I think it only kind to mention this.

The amateurs were in great force, and for the most part showed very fairly. Mr. Jovitt was in grand form again, and easily won the first prize for twenty-four. His great rival Hercules was first for twelve trebles, and Mr. Pochin secured first honours in eighteen. All these showed very well indeed. I was surprised to see how good Mr. Baker was after the storms we have had in the west, but be the weather what it may this grand grower always shows well.

The class for twelve Teas (open), was more hotly contested than any other, and the exhibits were very fine. When such great nurserymen as Mr. George Paul and Mr. Keynes were not placed the Teas must have been indeed excellent. Mr. Cant won the first prize and Mr. Corp the second. Modesty forbids my naming the third.

I do not presume to say a word as to the beauty of the Carnations, for that is no affair of mine, but the Show appeared to me wonderful, and a better alliance could not have been made than Roses with these lovely florist's flowers. But before I conclude I must bear witness to the hospitality and kindness of the Directors and General Manager. It is many years since I have had so pleasant a luncheon, or sat down at a more hospitable board, or received a kinder and more genial welcome than I did at the Aquarium. Mr. Wybrow Robertson fulfilled the duties of Chairman in a most excellent manner, and not one of the least pleasing incidents of this portion of the day's proceedings was his assurance that this was by no means the last of the flower shows to be held in the Aquarium, for in future years a Rose and Carnation Show would form part of the annual attractions. This good news will, I know, be welcomed by all your readers, and it may, perhaps, solace a few who, like myself, are sorrowing over the end of the Rose shows. To us, indeed, the summer days are over—the summer, that is, of our hopes and fears and sweet uncertainties, the heyday of our brief festal season, when the enjoyment of one brief month at the outside rewards us for the labour of a year; but still there remains to us the hope that for many another season we may be spared to enjoy and record a feast of such good things as was on Wednesday last the happy lot of your faithful—WYLD SAVAGE.

PETROLEUM VERSUS MICE.

I THINK your correspondent "J. H. Y." will find petroleum superior to carbolic acid in preventing mice from eating seeds, &c. I place my Peas, Beans, and other seeds likely to be attacked by mice in a flower pot (corked-up, of course), or any other vessel, with just sufficient petroleum that when stirred

round with a stick moistens the whole. I have never found mice to touch them after this. Petroleum besides is a fertiliser, carbolic acid is not, and likely to destroy the vital power of some delicate seed.—A. DECK, *Cambridge*.

EXPERIMENTS ON THE FLOW OF THE SAP.

[Read at the Scientific Committee of the Royal Horticultural Society.]

At the beginning of this session I drew the attention of this Committee to the course of the sap, being of opinion that recent researches rendered some modification in our views necessary on that subject.

The proposition that I submitted to the Committee was, pure and simple, that there was no such thing as descent of the sap at all, but that its course was always upwards. I found the Committee quite in accord with me, so far as regarded anything like circulation. I think most of them, if not all, repudiated any belief in the whole theory of the ascent of the sap by the fibro-vascular bundles of the wood and its descent by the cellular layers of the inner bark; but I found the majority still imbued by the theories of Sachs, and holding with him, and on his grounds, that descent by some means was absolutely necessary in respect that assimilation could only take place in the light, and consequently that the whole of that function must be performed in the leaf, whence the assimilated matter there produced must be transported in some way or other to the other parts of the plant in which it is found; and as these are lower down, and some of them even underground, as in the case of tubers, it followed that there must be a descent in some way or other, and the prevailing opinion seemed to be, as was, I think, first suggested by Mr. Herbert Spencer, that this took place by a slow swaying or wandering motion, by means of endosmose and exosmose, through the walls of the cells, which imperceptibly and independent of the current of the sap mixed the whole up together, or carried the different ingredients to where they were wanted.

Since I last spoke on the subject I have endeavoured to see if actual experiment would throw any light upon it.

I made experiments with the Vine, the Fig, the Horse Chestnut, and the Hyacinth, but as they all, so far as they went, tended in the same direction, I shall speak principally from the Vine, which was much more manageable and more readily took up my infusions than any of the others. Thanks to the experiments of Professor M'Nab and Professor Church, I knew of the virtues of lithia as an easily absorbed agent, whose presence could be detected anywhere by the spectroscope in however small a quantity it might be present, and I had the advantage of Professor Church's own kind assistance in determining for me whether it was present or not. As lithia, however, is colourless, I added to my infusions enough of litmus to colour them deeply, and I am bound to record as the result of my own experience that the lithia told me nothing that the litmus did not equally well. The combination of both, no doubt, adds to the confidence with which I can trust to my experiments, but the litmus had one great advantage over the lithia—that it might be easily handled, and dropped or spilt, without interfering with the experiment; whereas with lithia we have constantly to be on our guard against any careless dispersal of it—as, for instance, by allowing a drop to spill on the bark, or by using a knife that had been employed in cutting a portion of a branch that has been lithiated to cut one that has not. The form and proportion in which I used the lithia were five grains of citrate of lithia to each fluid ounce. To this I added a little glycerine, with the view of equalising the specific gravity of the mixture with that of the sap, and then as much as I found necessary of small lumps of litmus.

I then passed gutta-percha funnels over the shoots to be experimented on, and secured them as cups, with the shoots growing up the middle, by means of cork and tallow. I tried waterproof cloth, but it did not hold in, but the gutta-percha funnels did perfectly. My experiments were made in April and May, when the leaves were beginning to open. I put one cup on the stem of the Vine. It held perfectly, and no escape of the liquid took place. After the cup was properly luted to the stem with tallow I cut a nick in the bark a little above the fitting, and then filled the cup with the lithiated litmus mixture, so as to cover the nick. I then allowed it to remain on for six weeks, constantly renewing the mixture in the cup as it disappeared.

After the expiration of six weeks I took up the plant and examined it: and here let me say that the Committee and I are in accord as to what I should have found had Sachs' theory been well founded. I imagine that upon every principle I should, on the ordinary principles of gravitation, have found the severed vessels below the nick, and on the same side as it, filled with the infusion in consequence of its descent. So far as regarded that part of the plant it was no longer a closed tube, and there could be no ascent, but being, as it were, merely an open tube, whatever was poured into it should simply find its way to the bottom. And so in fact it did—the infusion below the nick descended to the very fibrils of the roots. In like manner the part above

the nick being a closed tube—closed by the cup at the bottom and by the leaves acting as a sucker at the top—we should expect that the infusion would ascend; and so it did, nearly as completely as it descended below the nick. But how as regards the parts that were on the opposite side from the nick? According to Sachs' theory, whether you call it the result of metastasis or of endosmose and exosmose, the infusion should have been found extravasated and unfiltered through that side, both above the nick and up the ascending branches, and in fact everywhere a little; but in point of fact there was not the slightest extravasation nor a solitary particle of lithia or litmus in any of these places. The depth of the nick was the measure of the extent of the penetration of the infusion, and it was as sharply defined as a line could be; and this is just what I said should be the case.

I said that the rapidity of the current would prevent any intermingling of ingredients by endosmose or exosmose. At night there can be no ascending current, for the force that produces it, the sun, is withdrawn, but the tube is full and in equilibrium.

To keep strictly within my experiences I must explain that this is the result of all my experiments as regards litmus, and of all but that on the Vine as regards lithia. The experiment as to lithia in the uncut side of the Vine could not be tested, because I sent Professor Church the portions of the plant to be tested, all cut up transversely, asking him to cut certain specified ones longitudinally, and then test them separately; but he explained that that would be a delusive test after the portions had travelled from London to Cirencester, for the lithia would have had time to pass by endosmose and exosmose from one side to the other, after the plant was cut in pieces: which of course it would, for there was no longer any current to prevent its infiltration; but the distribution of the litmus when the plant was newly cut showed clearly enough what the result of a search for lithia would have been at that time.

To my mind this is conclusive on the question. Sachs must be wrong, and we must now re-examine his arguments and see where the flaw lies. His position is thus stated in his "*Physiologie Vegetale*:"—"The absolute necessity (says he) of the intervention of light for assimilation in plants with chlorophyll is proved directly by their mode of development in darkness. When we cause seeds to germinate in such conditions, roots, internodes, and leaves are developed generally in proportion to the mass of the seed. When all the provision of elaborated principles contained in it are exhausted the development ceases. If up to that period the seed is allowed to germinate in the light and it is then removed into darkness the result is the same—the young leaves, although green, assimilate nothing; but if they are allowed to remain long enough in the light to have assimilated a little, there will be developed in darkness leaves and internodes until that new provision be exhausted also."

But there is one important fact that Sachs omits to keep in view here. If the plant in darkness assimilates nothing, neither does it take any food to assimilate. It is well known that plants do not feed in the dark, and nothing is easier than to prove it by experiment. Let anyone with a Hyacinth growing in water in a glass mark, by a thread or narrow strip of paper glued to the glass, the height at which the water stands at night, he will find it the same height to-morrow morning, but very different to-morrow night. But the fact is not disputed.

Now on what ground are we to hold that the reason why the plant does not assimilate is the absence of light in preference to the absence of food? Either will account for it, and one will suit Sachs' theory, but the other not. No doubt the food is not taken up because of the absence of light, but it may very well be that if the plant were placed in light so that it could take food generally, and some portions of it were secluded in darkness, we should find that assimilation went on as well in those in the dark as in those exposed to light; and this, in fact, is just what nature does with tubers. They are in darkness while the plant is in light, and they contain assimilated matter in as great abundance as any Apple in the blaze of sunshine. Now I object to a question of that kind, or, indeed, any other kind, being answered by giving the thing to be proved as part of the proof; but this is what Sachs does. He has to prove that assimilation cannot take place except in light. I offer an instance of its apparently taking place in darkness, and the reply is that it cannot be, because assimilation cannot take place in darkness. During the day the light and heat of the sun draw up the sap to all the terminal parts of the plants, such as the axial extremities of the branches, the buds, the leaves, the tubers (which are only subterranean buds), where it is partly evaporated and partly assimilated, and as it is used up the roots absorb a corresponding flow to supply the consumption; but at night, when the motive power is withdrawn, the upward flow of sap ceases, the roots become inactive and cease to feed; at the same time there is nothing to hinder growth going on, it may pile cell upon cell whether the machine is working or not, and it does so, but assimilation ceases. Sachs has confounded an accessory with a principle, and mistaken an effect for a cause.

Allow me, however, further to cite a well-known fact in favour of my views, which it reflects no credit upon us not to have

sooner so interpreted. I allude to what we see in the case of grafts. We know that the stock has certain properties differing from those of the scion. We all know that the properties of the stock affect the scion. They are carried up into its system, but those of the scion are not carried down into the stock. If the theory of descent and wandering and mixing of the sap were true the qualities of the scion ought to descend just as much as those of the stock ascend, but they do not. But some one may say, "Oh, but you are wrong; there are cases in which the influence of the scion has made itself felt on the stock." How many? I ask. Out of the myriads of millions of grafts that are made every year we hear perhaps once in a decade of some single plant where there is a doubtful appearance of a scion having had some influence on a stock, or rather, on a shoot from one. I am willing to take it as possible that such a thing may have, and that such a thing has occurred, but I add that it is still capable of explanation in accordance with my interpretation of the flow of the sap. It will be observed that such cases have never been recorded until after the lapse of a winter after the grafting, and, in fact, it is nearly impossible that they could. Now although I maintain that there is no descent of the sap, I never did (and could not) deny that there is a period (winter) when it no longer flows at all. The liquid part of the sap is evaporated, the more solid part is dried up, deposited or crystallised, or what is called "stored up" for next year. I imagine that this takes place pretty much simultaneously all through the plant, so that there is little sinking of the column of sap in the vessels. But it is possible that under conditions when there is an unusually large supply of sap in the vessels at the approach of winter, or in plants whose vessels are favourably constructed for it, there may be something like a disturbance of equilibrium, which will allow a portion of the sap belonging to the scion to ebb, as it were, below the graft, and, being there stored up and redissolved and carried up next year, may give rise to the doubtful phenomenon of which I speak; but I take my stand not upon exceptions but on the broad basis of an all but universal experience.—ANDREW MURRAY.

(To be continued.)

LEEK ROSE SOCIETY'S SHOW.

"THE rosy town of Staffordshire," as "WYLD SAVAGE" last year termed the "metropolis of the moorlands," had its carnival of Roses on the 17th inst., and it bore bravely comparison with any of its five previous celebrations. Of course, in magnitude it showed a falling-off when memory brought to view the glorious stand of seventy-two Messrs. Cranston & Mayos won so handsomely with last year, but remembering that the exhibitors were confined to the immediate locality, and that wind and rain had done their best to despoil the plants of their blooms, the display was both large and of excellent quality.

Of thirty-sixes the exhibits numbered three, and Messrs. Nixon, Eaton, and Clay (gardener to Mr. W. S. Brough), were awarded the prizes in the order named, their pans containing excellent blooms of Madame Lacharme, Annie Wood, Perle des Jardins, Louis Van Houtte, Maurice Bernardin, and La France. The twenty-four were a good lot all round, the prizes going to Messrs. S. Bratt, S. Eyre, and C. Roberts (gardener to Mr. Glover, Highfield). Twelves were strong, and the contests for sizes and pans of light and dark were well contested, the chief prizewinners being Messrs. Sheldon, Godwin, Cartwright, Newall, and J. Brough. Amongst so many good flowers the search for the premier bloom was like the proverbial hunt for a needle in a haystack, but ultimately a bloom of Charles Lefebvre was fixed upon as worthy of the prize.

Stove and greenhouse plants were staged on sloping banks each side the Rose tables, and added much to the general effect. Pansies were shown in great variety, Messrs. M. H. Miller and C. Eaton taking the chief honours.

The experiment of a promenade concert was tried and proved very successful, the attendance exceeding that of any previous year. The Judges were Messrs. Herbert, Sefton Park, Liverpool; Jones, Chester; Leicester, Macclesfield; and Sherratt, Knypersley.

DOUBLE YELLOW PROVENCE ROSE.

THERE is, and has been for several years, a plant of the above Rose growing on a north wall at Intwood Hall near here. The blooms are freely produced, they are of medium size, very full, and of exquisite cup-shape; the colour is rich deep yellow, the petals being of the same shade throughout. During its blooming season, which is short, no yellow Rose exceeds it in beauty. It grows freely either on the Briar or Manetti stock, but especially so on the latter.—J. E. EWING, Eaton, Norwich.

THE BEST SUMMER LETTUCES.—Paris Green is the best Cos Lettuce I have ever grown for summer use. It grows rapidly

to an immense size, folds its leaves in to blanch the centre, and the flavour is exquisite. Amongst the Cabbage varieties Tom Thumb forms a small useful compact head, and it is slower than any other in running to seed in hot weather.—M. M.

NEW BOOK.

A Book about Roses, How to Grow and Show Them. By S. REYNOLDS HOLE, Canon of Lincoln. W. Blackwood and Sons. Sixth Edition.

It is no misrepresentation on the title page to say that this edition is "revised and enlarged." The first edition had 277 pages, and this has 321 pages, besides an excellent coloured portrait of the author's namesake Rose, "Reynolds Hole." The volume contains directions for cultivating and exhibiting all the varieties, and is written in an attractive readable style not always characteristic of gardening literature. We have marked many pages for extraction, but must select the following, because it answers a correspondent who asks for "the names of Roses suitable for a garden near a large town."

"For Walls.—Gloire de Dijon, La Belle Lyonnaise, the Ayrshire, Sempervirens, white and yellow Banksian, Boursalt Roses—where a large space is to be covered, the Ayrshire and Sempervirens.

"Of Summer Roses.—The Common Moss, the Common Provence or Cabbage, Boule de Nanteuil and Kean, Gallicas; Brennus and Blairii 2, Hybrid Chinas; Charles Lawson, Coupe d'Hébé, and Paul Perras, Hybrid Bourbons.

"Of Autumnal Roses.—"Auguste Mie, Baronne Prevost, Charles Lefebvre, Comte de Nanteuil, Edouard Morren, Général Jacqueminot, Jules Margottin, La Ville de St. Denis, Leopold I., Madame Boll, Madame Boutin, Madame Clemence Joigneaux, Madame Victor Verdier, Maréchal Vaillant, Marie Baumann, Madame Charles Wood, Paul Nerot, Pierre Notting, Sénateur Vaisse, Hybrid Perpetuals; Armosa, Queen, and Souvenir de la Malmaison, Bourbons; Aimée Vibert and Grandiflora, Noisettes; Mrs. Bosanquet, China; and Climbing Devonensis, Gloire de Dijon, Madame Berard, and Souvenir d'un Ami, Teas."

NOTES AND GLEANINGS.

WE are informed that preparations for the GREAT EXHIBITION to be held in Carlisle on September 6th, 7th, and 8th are progressing satisfactorily, and that a really "great" display is confidently anticipated. Prizes amounting to upwards of £1200 will be competed for, and the schedule (which is now ready) is so arranged as to encourage the best cultivators to enter the lists. Entries close on the 30th of August. With a large and practical executive committee under the chairmanship of Mr. Baxter Smith, with Mr. William Thomson as manager of the show, and other able officials, the preparations cannot but be otherwise than well considered and well carried out.

— At the meeting of the Council of the Royal Botanic Society held on July 14th, a special GOLD MEDAL was awarded to Messrs. J. Carter & Co. of Holborn, &c., for the novel and extensive collection of fine-foliaged and flowering annual and other plants grown in pots from seed, which had been exhibited in the gardens of the Society during the month of June.

— A CORRESPONDENT writes as follows on the FRUIT CROP NEAR DERBY:—"Peaches, Nectarines, and Plums are a failure, though the trees were full of bloom and well protected with Parham's coping and horticultural shading. Apricots very few, though plenty of bloom and protected. Pears a general failure, not superabundant blossom. Apples, many trees failed, but some pyramids full of fruit. Gooseberries and Currants a fair crop. Cherries all dropped off except Morellos."

— "M. J. B." writing to us on BLACK PRINCE STRAWBERRY states:—"We grow a good many varieties of Strawberries, including Keens' Seedling, Oscar, Sir Charles Napier, &c., but not one of them has proved so productive as Black Prince. Its fruit is comparatively small, but is high in colour and is excellent for preserving.

— BESSIE JOHNSON is acknowledged to be one of the sweetest of Roses, and is an excellent variety for growing either in pots or in the garden. A climbing Bessie Johnson is, we are informed, established in the nurseries of Messrs. G. Paul and Son, Cheshunt, and which it is expected will prove an acquisition. We have seen blooms of a new bright crimson climbing Rose named Red Dragon, which has been raised at Waltham Cross by Messrs. Wm. Paul & Son. If this Rose

proves to be free in growth and floriferous it will produce a fine effect on walls and pillars.

— At no time of the year, writes a correspondent, do *Roses* strike more readily from cuttings than during the months of July and August. If wood that is partially ripened is made into cuttings—shoots that have bloomed—and inserted in a partially shaded border, nearly all of them will strike. The cuttings should be divested of all but the two upper pairs of leaves, and be inserted deeply and firmly. Water should be given and shade supplied in order to keep the foliage fresh and healthy, and roots will form the more quickly.

— MESSRS. BRADLEY & SONS of the Southwell Nurseries, Notts, have sent us specimens of LABELS which they have prepared for sale. Those made of horn are transparent and unique, and are far superior in appearance to those made of wood.

— We regret to learn that the *POTATO DISEASE* has shown itself at Chiswick, not merely that form of it known as the "curl," but the murrain, which has frequently proved so disastrous of late years. Should showery weather continue and a high temperature also prevail, the *Potato* crops cannot be otherwise than jeopardised, and it is advisable that crops in gardens which are approaching maturity should be taken up and the tubers be thinly stored, and much loss may be thereby averted; or if the haulm is pulled up, not cut off, when an outbreak of the murrain is threatened, yet before it occurs, the tubers if left in the ground will be safe.

— MR. H. S. JAMES, The Gardens, Westfield House, near Gloucester, informs us that he has a large plant of *PHLODENDRON PERTUSUM* which flowered in June, 1876, of which he has gathered three ripe fruit, and will soon gather the fourth. The plant is also in flower again, having had one flower open and another just expanding.

— AN American writer and admirer of *SUCCULENT PLANTS*, after alluding to the unique collections at Kew Gardens and at Hammersmith (Mr. Peacock's), states that "a well-filled succulent house would not be costly to keep or care for. Neither would such an astounding plant *mélange* have any resemblance to an 'old curiosity shop' crammed with inert trash and musty rubbish. Where there is life there are hopes of happiness present and to come. Although they are the oddest of all odd things, and the most 'wonderful wonders' in the vegetable kingdom, they are as intensely interesting as extremely curious. To us it really seems as if the Author of all good had some strange device in view when fashioning their fantastic forms, many of which are ultra-grotesque, while others are unrivalled in beauty. I have often noticed, both with amateurs and professionals, a strong desire to linger around them longer than with many other things more gaudy and gay, bloomed they never so grandly." The plants referred to are real amateur's plants, requiring neither close attention nor skilled cultivation, and a large and varied collection of them can be accommodated in a very small space.

— It is noteworthy how well even some of the most common of *HARDY PLANTS* are turned to account by the London florists. One of the most common and one of the most beautiful for the decoration of window boxes and window sills is the *Creeping Jenny*, *Moneywort*, or *Loosestrife*—*Lysimachia Nummularia*. Hundreds of this common ditch-side plant are grown in 5-inch pots, and cheer and brighten the dark courts of London. When the pots are placed in saucers of water and the plants are grown in the full sun their elegant pendulous growths become laden with golden flowers and produce an enlivening effect. The *Creeping Jenny* is a town plant of the first order of merit, and is capable of being turned to account in country districts as well as in towns. Neither is it wholly a plebeian plant, for Mr. Wills uses it largely and effectively for forming bright green fringes to the artistic groups of exotic plants with which he adorns the saloons of the aristocracy and the halls of public companies at their festivals. We would say a good word therefore for this common homely plant, because it is capable of cheering many an otherwise cheerless place, and growing and flowering where plants are rarely seen looking happy and healthy.

— It is reported, on good authority, that those who suffer from *RHEUMATISM* are cured in a few days by eating *ASPARAGUS*, while even chronic cases are much relieved, especially if they avoid all acids, whether in food or drink. The *Jerusalem Artichoke* is reported to have a similar effect in relieving rheumatism. Most plants which grow naturally near

the sea-coast contain more or less iodine, and in all rheumatic complaints iodine has long been a favourite remedy. Some physicians also recommend the free use of the *Tomato*. It is said to act very favourably upon the liver (in place of calomel), and its efficiency in relieving dyspepsia is remarkable. Raw or cooked it is considered to be equally wholesome.

— THE first annual Show of the newly established NOTTINGHAM HORTICULTURAL SOCIETY, which was held on the 19th, 20th, and 21st in the grounds of the Arboretum was, we are informed, a very good and successful one. The premier prize of £10 in the plant classes was won by Mr. Gadd, Woolaton Hall. *Roses* were numerous and excellent. The prizes went as follows:—For twenty-four cut blooms (open), first, Rev. Canon Hole; second, Mr. Frettingham; third, Messrs. Cranston & Co., Hereford. Twelve cut *Roses* (open), first, Messrs. Cranston & Co.; second, H. Merryweather, Southwell; third, Rev. Canon Hole. Eighteen cut *Roses*, six varieties, three of each (open), first, H. Frettingham; second, Messrs. Cranston and Co.

— THE aquatic house in the gardens of the Royal Botanic Society, Regent's Park, is just now highly worthy of a visit. The *VICTORIA REGIA* is in splendid condition, and is flowering freely. The first flower opened on the 20th inst., and was a foot in diameter. Each flower lasts for two days. It opens towards evening pure white, continuing open throughout the night, closing the following morning and expanding again towards the evening, but this time of a pink colour. It ripens seeds freely—in fact, the huge plant, with eight leaves averaging 6 feet in diameter, which is now flowering, has been raised from a seed which was ripened in the house last year, the seed being about the size of a Sweet Pea. The growth made in such a short time from such a small beginning is quite marvellous. Other aquatics now flowering are *Nymphæas*—*cyanea*, blue; *devoniensis*, rose; and *dentata*, white; also *Nelumbium speciosum*, the Sacred Bean of India, which has leaves nearly 3 feet in diameter, and *Syncharis Humboldtii*. On the roof of the house *Aristolochia ornithocephala* has a profusion of its grotesque flowers, and *Allamandas nobilis* and *Wardleyana* are in extremely fine condition. The plants in this house, and indeed in the gardens generally, reflect much credit on Mr. Coomber, the Superintendent, by their health and cleanliness.

— MR. L. FITT, in alluding in "The Journal of Forestry" to the AGE AND SIZE of YEWs, observes that the Ankerwyke Yew was a tree of considerable size in 1215, at the signing of Magna Charta. At Fountains Abbey, Yorkshire, there is one reckoned at 1200 years of age; St. Pierre in 1772 saw one in Lower Normandy which was planted in 1066; near Warblington, Hants, is one 27 feet in circumference; Crowhurst, Surrey, has one 30 feet 6 inches; at Leeds is one 31 feet round; Inchbrakie, near Crieff, Perthshire, has the second largest Yew in Scotland, which during a season of peril sheltered the great Montrose in its dense branches on one occasion. Of all these, Fortingall, Glen Lyon, Perthshire, bears the bell. In 1772 it measured 57 feet in circumference. Considering the slow nature of its growth Pennant's tree at Fortingall must have been a wonderful sapling at the beginning of the Christian era! Evelyn saw the hills of Surrey clad with Yews. The Darley Yew, Derbyshire, is reported to be the largest in the world. Besides being a charm for driving away the devil, a doctrine inculcated by monkish superstition, the tree was venerated in the early ages.

— THE agricultural department of Cornell University has received a valuable present from Dr. P. M. Hexamar of Newcastle, N.Y., consisting of five hundred VARIETIES of *POTATOES*. This collection took a prize at the Centennial Exhibition last year, and is considered, says the *American Cultivator*, to be the largest and most complete in the world. The *Potatoes* are to be planted in the University garden.

— IN the newly-formed State Board of Agriculture for Pennsylvania Mr. THOMAS MEEHAN has been elected professor of botany, and Mr. Josiah Hoopes professor of horticulture. Mr. Meehan is the accomplished editor of the American "Gardeners' Monthly and Horticulturist," a most valuable publication, and which states that Mr. Hoopes has been one of the most vigorous Presidents of the State Pomological Society, which practically takes under its protection all the more solid branches of horticulture, and is well known in connection with valuable horticultural services.

— We are very glad to record the continued well-doing of the SOUTH AUSTRALIAN BOTANIC GARDEN at Adelaide under the

directorship of Dr. Schomburgk, and to cite the following from the report of last year. "The interchange of plants and seeds with kindred institutions and private parties has been on the increase. Most of the plants of our extensive collection have been obtained by exchange; and had I to purchase the annual increase of our collection £300 to £400 would scarcely suffice, while our expenditure for the purpose is not £150. The Garden dispatched last year nineteen Wardian cases, containing about 800 stove, greenhouse, and native plants, and 1500 packets of seeds, which arrived at their destination generally in good condition. The recipients have been botanic gardens, Kew, Natal, Mauritius, Java, Singapore, Cape of Good Hope, Port Elizabeth, New Caledonia, Queensland, New Zealand, Melbourne, Geelong, Sydney, Tasmania, and Vienna. Collections of native seeds have been sent to the principal botanic gardens of England, Germany, France, Russia, and East India. Collections of seeds of Grasses and fodder plants have again been forwarded to East India and the neighbouring colonies. Our collection has been enriched during the last year with 500 additional species and hybrids containing many valuable plants from England, Germany, Belgium, India, America, Africa, Java, Singapore, New Caledonia, and the surrounding colonies. The numerous contributions from the South Australian public indicate the continuous interest felt towards this establishment; and these have also materially increased the collection by rare and valuable plants received from many donors."

—THE American "Gardeners' Monthly," in referring approvingly to the visit of HER MAJESTY to the Summer Show at South Kensington, observes:—"We are apt to laugh at the idea that the smile or the frown of any one human being should make all the difference between success or failure in a horticultural or any other exposition; but we must not forget that there is something in the average human mind that longs for a leader, and it will be to the everlasting honour of Prince Albert that he set the good example of patronising horticulture. We have no social aristocratic classes here, but everybody acknowledges and worships the aristocracy of intelligence, and it does not take long for this to be acknowledged, and for the possessor to be in some sort made to know that he fills this elevated seat in public estimation. Horticulture in America is, just now especially, suffering from the want of leaders among those who worthily possess influence if they would only use it."

CUTTING ROSES FOR EXHIBITION.

OUR friend the Rev. Mr. Camm has asked me to give a reason for the unorthodox practice of cutting Roses in the sun, which I have recommended for many years. I am glad he has tried it for himself successfully, as he will, therefore, lend me a more patient ear.

I was first led to the practice by observing during a cold dry wind with no condensation of dew how very much some fine exhibition flowers which I had been anxiously watching were retarded and kept back on the trees. After making several experiments to satisfy my mind I was led to the conclusion that the safest plan and the best time to cut in very hot weather for travelling was at six o'clock in the morning and three in the afternoon. At six o'clock you may cut flowers with impunity for the next morning's staging, but they must be large, deep, full-grown, half-opened buds, which if left on the trees until ten o'clock would be, to use a common expression, "blazed out." Very double massive varieties may be cut in a more expanded state. Remove these to your boxes on the ground in a cool dry shed or even cellar, without sun or much light. Prop open your boxes about 6 inches, so much the better if a current of air can be admitted under the door from the north side. It is often well to hang a thick mat in the doorway within a foot of the ground, so as to admit only the coolest air from the surface. Go round again at three o'clock in the afternoon and do precisely the same as before. Cut only the large opening blooms, and you are quite safe for a night or morning journey. You must not cut the large expanded flowers in the morning, which appear fresh and beautiful with the dew on them, having their centre petals closed or partially folded up. These were "blazed out" the day before. The moment the dew is evaporated these grand flowers will quickly fade and disappoint you at the last minute. I attribute this to colour being an ammoniacal compound; ammonia having a great affinity for moisture the colour is thereby quickly discharged and fading takes place, the rapid action of

evaporation affecting even the light and white varieties. We often read descriptions of a brilliant French Rose edged with light. This is a case in point.

Cutting over the ends of your Rose stems when you rearrange your boxes in the morning helps to get more water into their tissues; keeping your green moss as dry as possible around them has a tendency to bring up the centres of your blooms, which is very desirable.—HENRY CURTIS, *Devon*.

WHOLE VERSUS CUT POTATOES FOR PLANTING.

A MONTH or two ago "A NORTHERN GARDENER" took occasion to say that my plan of planting Potatoes whole was not the best one. A crowd of stems and small tubers were to be the result. Nothing could be further from being correct than this. Our garden Potatoes will cover about an acre. Every one of the tubers were planted whole, and I have seldom seen a more promising lot of Potatoes. But this is not all. We have been lifting Potatoes out of doors for the last six or seven weeks. The sorts are Rivers' Early, Ashleaf Kidney, Gloucestershire Kidney, and King of the Earlies. A better crop no person need wish to see. From one root I lifted to-day twenty-five full-sized kidneys. There is a south border here on which early Potatoes have been grown for more than a dozen years. Formerly the sets were cut, this year they were planted whole; and while the crop in previous years was much below the average, it is better this season than it ever was. The cottagers about here to economise seed cut the Potatoes to every eye. When one fails there is a blank; and worse than this, this year the blight is extensive within a stone's throw of our own crops, and yet not one root of the latter is touched in the slightest. In this short distance there cannot be much difference in the soil nor atmosphere either, but remember there was in the sets. Now, as to the disease, and cut *versus* whole Potatoes, I think the whole tubers have the advantage. The late Mr. Paterson of Dundee said, and many think, that by cutting a little bit of the end of each tuber, or cutting them into pieces, the seed decayed quicker and did not rob the young tubers of their nourishment. I think differently. I know of nothing that will cause young Potatoes to become diseased quicker than having an old rotten one in their midst.

Potatoes when planted whole do not decay at all under the soil, and it is a simple matter to pick them out as the whole are lifted. If any of your readers do not remember my mode of choosing and dealing with seed Potatoes, as I stated in a bygone number, it is this:—Use all the large tubers; preserve all those about the size of a small hen's egg for seed, plant them whole, and give the very small tubers to the pigs. —A KITCHEN GARDENER.

[We consider your plan good, and you have proved that it is successful, but we think "A NORTHERN GARDENER" did not advise the cutting of kidney Potatoes.—EDS.]

LOBELIA EMPEROR WILLIAM.

THE flower is dark and distinct, with a well-formed white eye, and in habit is quite a little bush, answering admirably for carpet bedding. I found it did not grow exactly true from seed; still the variation was very small—not more than 10 per cent., but even at this rate it would greatly mar the effect in a piece of ribbon or carpet bedding. I at once came to the conclusion that if I let my chances for cuttings alone till the autumn there was every chance of the true and untrue cuttings getting mixed again, so in July I selected a few of the most compact plants, which I cut down near the surface of the ground. These threw up hundreds of fresh young cuttings, a batch of which I inserted in August. They grew well, each being capable of producing eight or ten plants in the spring. I mention this Lobelia because it is an excellent one, and because it is by cutting a few plants down at this period of the year that plenty of good cuttings are produced for securing a full stock of healthy plants. If the plants are not cut many of the dwarf free-flowering Lobelias produce but few healthy cuttings.—B. G., *Co. Down*.

DISEASED CUCUMBER ROOTS.

WE have received from "C. B. E." specimens of Cucumber roots distorted and enlarged by clusters of white knobs.

The root-nodules in question are generally assumed to have

a fungus origin, but the Rev. M. J. Berkeley long ago described the disease, and showed it to be caused by a parasite of another nature. The description he illustrated with the utmost accuracy. It would seem that the pest which causes the mischief is not always readily seen, or maybe it escapes into the surrounding soil, or, after working the mischief, perishes; but that it is sometimes difficult or even impossible to detect Mr. Berkeley himself confesses. On this account Mr. Berkeley's observation has unfortunately been questioned, but he has quite recently been able to satisfactorily confirm its positive accuracy in *Gardeners' Chronicle*, Sept. 5th, 1874. For our

part we have frequently seen the interior of the nodules just in the condition described by Mr. Berkeley, with the parasites in all stages of growth, from the egg condition upwards.

Our illustration, prepared by Mr. W. G. Smith, represents on the left the diseased roots natural size, and on the right a thin slice through one of the nodules of the roots. The latter is an exact reflection from a camera lucida attached to the microscope, and shows the cellular tissue, A; pitted and spiral vessels, B; the worms coiled up in the eggs, C; worms emerged, D; and empty eggs, E, from which the worms have escaped.

Fig. 20.—THE DISEASE OF CUCUMBER ROOTS, ENLARGED 160 DIAMETERS.

The disease is therefore caused by the presence of minute worm-like infusoria called vibrios, creatures common in decomposing infusions, &c. We have carefully examined your roots with the microscope, and the vibrios as originally described by the Rev. M. J. Berkeley are present in abundance from the egg state upwards. It is much easier to examine and describe a disease than effect its cure. The recommendation generally is to utterly destroy all the diseased roots and the surrounding soil. Whether these nodosities are present or not Mr. Smith finds the nematoid worms in all parts of Cucumber plants when suffering from disease. He has even found them in the cotyledons, and believes them to be the same species common in the juices of dung, in impure (and apparently pure) brooks, in mud by stream sides, and in rain. They are very small. They are supplied to the Cucumber plant in the manure, the manurial waters, or even water from brooks. They speedily eat into the root fibres, and there lay their eggs. The eggs are soon hatched, and the new family eats away further up and more eggs are laid, and this goes on till the whole plant is half rotten. If when the seeds are planted the earth is

saturated with a solution of Mr. Smith's "salus," 7 lbs. to fifty gallons of water (or it may be stronger), he says every worm, and egg, and infusorial animal will be destroyed, and the Cucumbers will be perfectly healthy because the parasites are gone. Mr. Fish and many other growers have now tried this, and he has not heard of one failure; on the contrary, several men who were totally unable to grow Cucumbers at all owing to disease now have good crops. This applies to Melons equally with Cucumbers.

HALL PLACE.

REFINEMENT and culture are the sure indications of an advanced stage of civilisation. A taste for the beautiful and the good is implanted in our nature from earliest infancy, growing with our growth if it be fostered and nourished, but becoming dwindled and almost lost if it is not so cared for. Among the many influences which combine in our own happy country to elevate us it must be granted that horticulture plays no mean part, softening, refining, and imparting a tone such as nothing

else can do. That this influence is now very generally recognised and understood there can be no doubt, for the number of public gardens and parks is constantly increasing, and it is an acknowledged fact that one of the greatest boons a rich philanthropist can confer upon a town is to give it a public garden. How highly such a gift is valued and appreciated the givers, perhaps, hardly understand; nor need I dwell upon it, much as it tempts me, for the fact is patent to all that tone to the mind and health to the body are imparted by such gardens, which have not inaptly been termed the lungs of a crowded community, tending to prolong life as well as adding to its enjoyment. No longer can the advocate of communism point to the "grim exclusiveness" of the enclosures of landed proprietors, for those whom he strives to render dissatisfied with their lot often now are in the enjoyment of a garden that is not unfrequently infinitely superior to "the squire's."

The seats of our landed proprietors are, however, undoubtedly the crown and glory of the land; moreover, they are fast growing in number, especially in the more picturesque parts of Sussex, Surrey, and Kent. Nor is this work of progress and improvement confined solely to the formation of new places. Old mansions and gardens are being rebuilt and remodelled—not always perchance with the approval of the antiquarians, but certainly with that of those caring for real improvement, while they would gladly cherish all that is really beautiful and interesting. Fig. 21 represents what is a striking example of an old place rebuilt, enlarged, beautified. It is one of the many fine places which lie within a radius of a dozen miles of Tunbridge Wells, and is quite worthy to take rank with Eridge Castle, Dunorlan, Possingworth, and Brambletye, all of which places have been fully described in these pages; but of Hall Place (the residence of S. Morley, Esq.)

Fig. 21.—HALL PLACE.

I have no report to offer now—indeed, a detailed statement would be inappropriate for interweaving with these general notes; it must suffice, therefore, to state that the general features of the kitchen gardens and glass houses are striking only from the disconnected straggling manner in which they are disposed, but that the lawns and pleasure grounds are really excellent, being very extensive, agreeably interspersed with shrub groups and fine examples of Conifers and deciduous trees. There is also a quaint Italian garden near the house, a carriage court of ample proportions and dignified aspect, with a very bold sweep of well-kept turf stretching gently downwards to a lake of considerable size, beyond which the pleased eye wanders over more turf to stately timber trees dispersed in the foreground, but thickening into deep shade in the distance, with vast beds of Bracken visible among the backward trees, and advancing so as to form an irregular fringe around the bases of the foremost, just in the way that artists love to depict. Groups of fallow deer, too, impart animation to a scene abounding in beauty and brightness.

I know nothing more pleasant after beholding such a scene, and enjoying it too, even if but for a few brief moments, than to pass outwards from the boundaries of the park, as I did here, into a village abounding with cottages neat, cosy, and compact, surrounded by well-tended gardens, every wall, building, and enclosure in excellent repair, betokening the fostering

care and bountiful hand of a wealthy large-hearted landlord; and moreover proving, if proof were wanted, by the abundant floral embellishments in the windows as well as gardens, how much our common nature is influenced and affected by flowers; and I doubt not that intercourse with the good folks whose surroundings impressed one so favourably would have tended to strengthen my faith in the refining influence of gardens.

—EDWARD LUCKHURST.

AQUILEGIAS.

I SEE one of your correspondents (Mr. Douglas) has been fortunate in raising two new varieties of this very interesting family, and I for one agree with him to the very letter as to the merits of these hardy, beautiful, and free-flowering plants. I grow all the sorts I can obtain, but some I have discarded. *A. aurea* and *A. alpina* are scarcely worth growing, but they bloom freely. *A. glandulosa* is very fine, but rather a shy bloomer, but in some cases it blooms pretty freely. *A. carulea* is a bold-looking fine sort, and blooms more freely than *A. glandulosa*. There is a spurious sort of it to be met with, and is much paler in colour than the original, and is worth growing as a variety. *A. Witmani* is a very free bloomer, and resembles *A. glandulosa* very much. I saw a plant of it this year with 130 blooms on it, and I secured the plant and

made seven out of it. *A. pulcherrima rubra* is a distinct free-blooming sort, and worthy of attention. *A. pyrenaica* is a dwarf alpine variety, but in my opinion not so good as those I have named, and never flowered freely with me. *A. chrysanthia* is a great beauty, and blooms later than any other I know, flowering very profusely. I have a plant of it with at least 150 flowers on it in all stages, and it has been blooming for ten days and will continue till the middle of August; it is nearly 5 feet in circumference and grows 2 feet high. It is the best plant I ever saw of it, and has not any attention beyond a good soaking of water in dry weather. The colour is yellow. I consider it the most interesting *Columbine* I have seen. I saw a seedling named *A. trinityensis* at the Rose Show in Edinburgh last week which had a first-class certificate; it resembles a variety of *A. carules* in form, but is yellow in colour.—J. ADDISON, *Ormiston, Edinburgh*.

TWO-DAYS SHOWS—FIXTURES.

HAD the late Show of Roses at the Westminster Aquarium been a special show of that flower it would not have been supported so well as it was by rosarians. They know that two-days Rose shows only bring disgrace on a beautiful flower, for the Rose on the second day is as ugly as a Rose can be, hence the almost unanimously expressed wish that Rose shows be limited to "one day only." That is a principle that has been adopted by the National Rose Society, the influence of which has been sufficiently powerful during the first year of its existence almost, or quite, to "stamp-out" the plague of two-days shows. But Roses were exhibited at the Aquarium as subsidiary to the Carnations, the Rose section having been a mere adjunct of the National Carnation Society's Southern Show.

No doubt the Aquarium Company had good reasons for continuing the Show for two days. In all probability the returns on one day would not have compensated for the cost that had been incurred, and it is not in human nature to "lose money" if the loss can be averted. No doubt also it was considered that Carnations would continue fresh and attractive during two days, and that a shadow of beauty would remain with the Roses. Generally Carnations keep well in water, but the Show of last week proved that they will not keep at the Aquarium. The Show of these flowers was on the first day a gratifying success, but on the second day it was a miserable failure. The gas-lighted and vitiated atmosphere of the structure makes it a very chancel house for flowers. The condition of the plants tell how destructive the building is to vegetation. It is no longer a "garden," neither can it be made one, except by introducing fresh plants almost daily; and as to cut flowers, the very breath of the place during a few hours of gaslight is deadly poison.

Flower shows in such a place can only be made successful by adapting them to circumstances. There have been two two-days Rose shows, and the results were the same in both instances—namely, the Roses on the second day withered and dying, and many visitors consequently disappointed and grumbling. It is to be hoped that we have seen the last of such shows in the Aquarium. The Carnations on the second day were, to the surprise of many and the disappointment of not a few, almost or quite as unsightly as were the Roses. It is to be hoped that the first failure (the second day's failure) will be the last, and that no more two-days Carnation shows will be seen in the building. Exhibiting flowers when in such a miserable state can only do harm by bringing both flowers and exhibitors into popular disrepute.

Admitting that it is necessary to continue an exhibition such as the one alluded to for two days, would it not be far more satisfactory to have the Carnations treat on one day and the Rose feast the next? The Carnation Society has proved itself strong enough to produce a show of considerable extent and undeniably attractive; is it not strong enough to stand alone? At any rate, if it needs a prop let it be of plants or fruit—Covent Garden commodities; anything but Roses. The Rose is worthy of a better position. Let the Carnations come on the first day and the Roses on the second, and the public will come in as great numbers as if both were shown together and half the time in a miserable state, and will return much better satisfied than if they had inspected faded and unattractive flowers. Is not this proposition worthy of consideration and discussion? What do the exhibitors say?

The question of show fixtures is also a matter of some importance, and especially Rose-show fixtures. It is compulsory

that many shows must be held during an extremely limited period, and their dates cannot be arranged with advantage unless arranged systematically.

Every Rose show of importance requires the presence of the great growers to make it successful; but even they, great as are their resources, cannot be in two or three places at once, nor can they cut to advantage and travel with reasonable comfort without a day occurring between the shows. A very practical rosarian and great exhibitor remarked at one of the meetings that his firm could show oftener and better if the shows were systematically arranged, and he thought that the Committee of the National Rose Society might do much in co-operation with committees of local affiliated societies in preventing such a crowding of shows and a clashing of dates as not unfrequently occur. The holding of two shows in which so many people have an identity of interest on the same day cannot but do injury to both. Common prudence suggests the desirability of keeping clear of collisions by every possible means. The holding of two shows on the same day is akin to running two trains in opposite directions on the same line of rails. The result is a collision and disaster to both.

It is not to be expected that any particular day can suit any particular individual; that is not the question. The individual must stand aside if he is an impediment to the general community. No day can be mentioned for a show to which objection cannot be urged. Not long ago I heard complaint that a show in a certain place on a Tuesday was too near Sunday, yet in the same week all the chief nurseries were exhibiting some distance from London on a Saturday.

Saturday does not appear to be an unsuitable day for a Rose show at least; at any rate some of the best shows have been held on that day. It is a popular day. Why, then, should not Tuesdays and Thursdays be popular also? That would bring in three days of each week and one day between each for preparation, advantages which cannot be secured by any other arrangement—that is, of course, applying the days to districts where the same exhibitors have a chance of meeting.

Under some such system of arrangement I think the Rose shows would be better—better for societies, exhibitors, and judges. Would it not be advisable for the Committee of the National Rose Society to have a voice in the selection of show days of such societies as are in amalgamation? Rosarians, consider the matter.—EX-EXHIBITOR.

BEAUTY OF OXTON PELARGONIUM SPORTS.

I SEND you two blooms of Pelargoniums. The semi-double one is taken from an old plant of Beauty of Oxtou. Last season, wishing to increase our stock of this variety, we took some cuttings from the roots of this plant, and had the labels marked "Stock" in order to keep them from being sold. On looking through our stock plants we found the enclosed bloom, which is quite dissimilar to any other variety we have, growing on a plant marked Beauty of Oxtou, and on further examination found another plant which had sported in a similar manner. Can any of your readers say whether they have found the same thing occur from propagating from the roots of Pelargoniums? Those cuttings taken in the ordinary way are quite true, but these are not only sports in flower but also in foliage. As you know, the foliage of the semi-double Pelargoniums is somewhat crimped at the edges, whilst this is perfectly flat like any ordinary show Pelargonium.—ALFRED H. PEARSON, *Chilwell*.

[The flower of Beauty of Oxtou is true; the other is a flower of a plain, not crimped leaved, French Pelargonium, quite unlike Beauty of Oxtou. We had previously heard that some of the "regal" Pelargoniums do not come true if propagated by the roots, and shall be glad to have further information on the subject.—EDS.]

ECONOMY IN FUEL.

I HAVE no doubt that it has often occurred to persons when they have seen the glow from the furnaces at night that a large amount of heat must pass off unutilised into the atmosphere. In all probability half passes off in this way, and where coals cost 30s. a ton any plan to reduce the consumption to one-half would suit the pockets of some people. I need not enter into the different plans I tried before I discovered one to prevent the heat passing out of the flue. I had 60 feet of iron tube of 1 inch in diameter (inside measure—

ment) wound into a coil of from 5 to 6 feet in length. This coil was attached at one end of the tube to a saddle boiler, while the other end of the tube communicated with the 4-inch pipe which traversed the house. Over the coil I built a dome of firebrick, leaving a small space for the flame to flicker round the tube. This apparatus I placed horizontally inside the house, the feeding door being on the outside. The flue at the further end of the coil was carried up a few inches, and then level over the whole of the apparatus, and then out of the house immediately above the feeding door. Much to my surprise I found that no heat passed out of this flue, the whole having been exhausted by the water in the coil. The rapidity with which this house is heated, and the small amount of fuel consumed, is extraordinary. I am now about to have another constructed on the same plan.—OBSERVER.

ROSE MDLLE. MARIE FINGER.

My friend Mr. Beachey asks if I have any eye to colour. I hope I know a Lily from a Pæony, but perhaps I am colour blind on certain occasions, and I must own that I have not noticed any difference of shade in the colouring of Marie Finger and Mdle. Eugénie Verdier. My impression was that if any difference existed at all it was in form, not colour. I rarely see Marie Finger so globular as her twin sister, but I am informed by Mr. Jowitt that (to my great surprise) Marie Finger is superior in form to Eugénie Verdier. As Mr. Beachey claims superiority in colour also, it shows that there are two good rosarians who make out that Marie Finger is the better of the two. I have not grown the two side by side yet, as I try and vary my colours as much as possible.

Soil, in my experience, makes all the difference in colouring, and perhaps Mr. Beachey's soil may suit that particular Rose so well that he excels in growing it more than he does with Eugénie Verdier. However, I willingly concede my opinion to his, the more so as I look upon the Rose as a great gain to the lighter sorts.

"THE HEREFORDSHIRE INCUMBENT" objects to Mr. Hinton classing the three brothers—Ferdinand de Lesseps, Maurice Bernardin, and Exposition de Brie—as the same Rose. Leaving out the question of wood, I should much like to see how my friend describes the difference between any two of the three.

I cordially concur with Mr. Hinton in his desire to leave the Tea election for another season. His hands are quite full enough already, and the great want this year is lists of the best exhibition Roses, and given only by those growers who have won a leading prize at the great shows of the last few years.—WILD SATAGE.

PROPAGATION BY CUTTINGS.

"PACEX" asks for information about the making and management of cuttings of Roses, Pinks, Carnations, Pansies, Rhododendrons, &c. A wise man is "PACEX;" for that "&c.," although an abbreviation, is wonderfully inclusive, pointing in this instance to all such plants as come within the scope of an amateur who is the fortunate possessor of a really good little garden. Gladly do I respond to his appeal now when so many plants have growth in the best possible condition for our purpose, and when the temperature of the soil and air is so warm as to ensure success without artificial aid, other things being equal.

I always like to know the reason why a given practice is adopted; and "PACEX" evidently shares this feeling with me, for he asks why he is advised to insert some cuttings in the shade and to expose others to the full glare of the sun. Such a question suggests that the first principles of the operation of striking cuttings are not generally understood, and therefore I cannot but be doing good service in showing what those principles are.

What, then, is a cutting? In most instances it is the shoot of a plant cut off when in full growth in a tender succulent condition, and therefore quite certain to wither and die very quickly if prompt measures are not taken to prevent the evaporation of its juices. Now the shoot of a Pelargonium is so stout in texture and so abounds in succulent matter that prompt insertion in moist soil, followed by a thorough soaking from the rose of a water pot, renders it perfectly safe for the moment, although the border in which it is inserted is fully exposed to the sun. It may afterwards be necessary to water it twice a day, but it requires no shading excepting perhaps

for the first two or three days, and that only if the weather is exceptionally hot. But a Verbena shoot if thus exposed would die; nothing could save it, simply because its slender stem and thin foliage lack the juicy stores and robust proportions of the Pelargonium; therefore we insert it in a shaded frame, or, better still, under a low bell-glass, in order that the part above the soil may be constantly enveloped with air that is heavily laden with moisture. I am particularly anxious that this should be set forth plainly, because when it is once understood a host of contrivances will present themselves to an ingenious mind.

No hotbed is necessary at the present time. We may even dispense with a frame, and by pressing a bell-glass firmly into the soil inside the rim of our cutting pot we may with one turn of the hand form a portable propagating house, which alone or with hundreds of others may be placed for shade behind a wall or hedge. I have even, when unable to meet an immediate demand for small bell-glasses, purchased some common half-pint tumblers, and very well remember my first batch of Clematis cuttings was inserted under some of those tumblers, the cuttings striking root freely without a single failure. I am not now writing for the "great gardeners," but for the especial good of the very numerous class who must make shift with various and simple contrivances, and who frequently do so to such good purpose as to obtain results that are equal to those which one sometimes meets with in gardens abounding in every facility of ways and means.

Cuttings of Pansies and all the Viola tribe, with Pinks, Carnations, and a host of kindred plants, are usually inserted in a border at the foot of a north wall, sometimes under hand-glasses, and failing them in the open border. This is done because such cuttings emit roots freely in such a position. Hand-glasses are certainly preferable, as they tend to promote a more prompt and ready emission of roots, and also check evaporation from which Carnations are apt to suffer.

Rose cuttings should be made from stout shoots which have borne flowers in the current season, as was explained in these pages very lately. I used formerly to consider the protection of a glazed frame necessary for them and have advised its use, but subsequent experience has led me to discontinue it and to insert the cuttings in an open border a little deeper in the soil than when inserted in pots under glass. If due care is given to this and to select shoots which are stout in growth and firm in texture, I fail to see why all sorts of Roses may not be raised from cuttings with the greatest ease. I know well that there are very few sorts which fail to grow freely and well upon their own roots when under really good culture. But the Rose is a greedy plant, requiring liberal supplies of rich food, and no half-and-half measures will answer in its treatment.

It is not always that cuttings of bedding plants such as Heliotropes, Verbenas, Petunias, Lantanas, Cupheas, and Ageratum can be made so early in the season as could be desired, nor is it always an easy matter to obtain a supply of cuttings when the beds are crowded and the growth old and hard. It is therefore good practice to plant a reserve plant or two now in a cool border sheltered by a hedge or north wall, solely with a view of providing a few stout cuttings for stock later on. This method is especially applicable to Verbenas; and then if cool autumnal nights steal upon us before the cuttings are in we have only to make a slight bed of grass-mowings and leaves whereon to place our frame or hand-glass, under which we plunge our cutting pots to the rims in the bed, and a supply of sturdy plants is quickly forthcoming.

Rhododendrons are generally raised by sowing seed, by grafting, and by layering. If "PACEX" wishes to increase the number of any favourite sort he will probably best succeed by pegging-down—layering—some of the lower branches 3 or 4 inches under the soil. I prefer doing this fully a month earlier, just when the new growth appears, but it may be done now onward to the autumn successfully.—EDWARD LUCKHURST.

TREES AND FLOWERS.

AMONG the chief silent friends, comforters, and cheerers of man are trees and flowers. I have sometimes asked myself, Which gave me the more pleasure? Perhaps a reader will answer readily, "Flowers." But think a moment. Time and continuity are great tests of friendship, and these tests trees will bear; for flowers soon wither, die down, perish, but trees are more constant—they abide by us always, they are neighbours, I might almost say, for ever.

Not only are trees with us in leafy June, one of the most

enjoyable of months of all the year, in their bright green splendour, but when autumn comes there they still are—clad in another garb of beauty, more gorgeous though not so glad; and even in winter, who would wish to be without their tree neighbours? The perfect symmetry of a tree is never better seen than in winter, and the dullest eye and heart recognise their vernal beauty; also, there are trees which openly show no change in their leaves, and so gladden us all along the dreary season by their greenness. Moreover, in those that shed their leafy garb see the fantastic forms of beauty which they become when decked by a hoar frost or a snow storm, especially by the former. I would say that nothing takes off the dreary feeling of winter so much as the presence around us of fine-grown trees. When all that out of doors formerly cheered us is gone; when flowers, corn fields, and green grass are no more; when hedges have become mere dark lines or intersected branchlets, yet the trees are there around us still, and present with us to comfort us.

Perhaps no one can so thoroughly appreciate the value of fruit trees as one born or having lived many years among them. The treeless plains, like prairies, are akin to the ocean's calm, and on them companionship seems lost. We read of one where the architect wished to cut away a noble old tree, who said, "No! move the house, but you cannot grow such a tree in my lifetime. Oh! the hours of pleasure I have taken under its shade, and the sweet memories of youth and its associates they bring are beyond all art's splendours."

Let trees have their meed of praise. They are the constant abiding friends to us. They vary indeed according to season, but each variation is a separate beauty; bud, leaf, lighter at first, then darker; then come the richly autumnal tints, and then the grand visible branches stretching far and wide during the winter months; long, low-hanging limbs lying above and not far above the backs of animals that minister to our daily comforts, and when the heavy frosts come the whole tree is standing jewel-decked.

But let flowers have their meed of praise. They are the loveliest of all things while they last; bright visitors whose coming is looked forward to with longing—bright visitors that leave behind them pleasant memories, who are talked of after they have left us.

I liken perennials to old friends that come and stay with us a few days each year—old, old friends, whom we have known so many years that we cannot tell exactly where our friendship began. Then as flowers differ in appearance, I liken them to different friends. Some I compare to quiet maiden aunts, whom all the children gather round and love, whom the youngest—that little impatient youngest one—obeys readily and feels happy in so doing. Other flowers, not a bit like these, so my fancy runs, are so bright and good-looking that I compare their visit to that of some bright-eyed merry girl—merry, so merry that she makes the house ring with laughter—merry, so merry that she even "makes a sunshine in a shady place," and her visit has made such a difference to the quiet-home routine that when she is gone you wonder and mark the change, and sigh to think that in a few years the world's heavy weight will subdue to a quieter tone even that merry laugh. And so of other and other flowers.

Lastly, of trees and flowers: the former we wish to have, the latter we must have, as the child will pluck the Daisies. Happily our craving can be readily satisfied, for flowers are easily carried into the heart of great cities, placed by sick beds, found or taken everywhere. No need of choice sorts for these purposes. The nosegay of common flowers from a common garden, the Lilac or Spiræa, or those from the woods are sufficient unto the sick, are welcome and give untold happiness.—F. R. ELLIOT, *Cleveland, Ohio.*

THREE YEARS' EXPERIENCE IN A GREENHOUSE. PROLOGUE.

HAVING as an amateur been very successful in raising a rather large family of plants and flowers—for I always call them my children, and perhaps tend them with as much loving care as though they were endowed with human instead of plant life—I have for some time past thought of giving my experience for the benefit of those whose tastes are akin to my own but fail to attain the results. I must first say that my knowledge of plants and flowers is so exceedingly limited that I am really not certain when I raise a good thing, having had so few opportunities of comparison, and it is of course only by comparing that one can judge; so it suggested itself

to me to write to the Editors of our Journal, sending at the same time a few specimens of the flowers I raised, and ask them if they were really worthy of commendation. I did so, and received a most satisfactory answer; hence this attempt to give my fellow workers a few simple results.

I began with a frame, and would advise others to do so, for a frame is but a greenhouse in miniature, and we certainly ought to master our letters before we attempt to read. A frame—well, what is a frame? Mine was an old box 24 inches by 12, cut off on a slant and covered with a single sheet of glass simply laid on the top. In March I sowed half with *Tagetes* and the other half with *Phlox Drummondii*. When about 2 inches in height I transplanted the best of the seedlings to another frame about 2 inches apart, let them grow, pinched out the tops in about a fortnight, then at bedding-out time (May 20th) planted them out. Well, you will say perhaps, "What then? We have grown the same things without all that trouble." Ah! but how about results? The *Tagetes* were enormous, and though I planted them 18 inches apart their frond-like leaves overlapped; and as to the *Phlox*, my friends told me they had never seen their like though they grew them—and why? Simply because they had never taken the trouble. I remember reading in our Journal how to protect Peas from birds by stretching black threads across and across the rows. I tried it, found it thoroughly effectual, told my friends who complained bitterly of the birds eating half their Peas. What did they do? Used white thread instead of black, though I had given them the reason for using the latter—viz., that the birds seeing the white threads avoid them, but the black being invisible scare them on coming in contact, the birds evidently suspecting a trap. However, they who used white thread lost their Peas, which is a grim satisfaction to those who gave tested and practical advice.

I trust my readers will not be impatient to get to the greenhouse. In my next paper I will relate how I constructed my greenhouse for £12 15s., including a thoroughly efficient heating apparatus, not only to grow *Geraniums*, but such plants as *Gardenia*, *Stephanotis*, *Gloxinia*, &c.—*RESPICE FINEM.*

ROYAL BOTANIC GARDENS, KEW.

[THE Report for the year 1876 has been issued. We extract the following.]

The number of visitors exhibits a considerable falling-off as compared with last year, being just below 600,000 (596,865). This is the smallest number since 1872. A comparison of the figures given in the appendix will show that the diminution in the whole attendance is largely accounted for by the diminution in the months of May and June, during the former of which cold and easterly winds prevailed. On the 7th of August the Royal Gardens were visited by 64,163 persons, the largest number which has ever been recorded for any one day.

In the Palm house a great improvement has been obtained in the general effect. It has been found necessary to cut down nearly all the large Palms on the north side of the transept, and plant out others in their place. The following are the more important changes:

Arenga saccharifera cut down and replaced by *Sabal glaucescens*. *Livistona inermis* (*L. australis*), "Bot. Mag." 6274, cut down and replaced by *Phoenix dactylifera*. *Sabal glaucescens* transplanted and replaced by *Astrocaryum rostratum*. *Acrocomia sclerocarpa* cut down and replaced by *Thrinax aculeata*. *Sabal umbraculifera* cut down and replaced by *Livistona chinensis*. *Veitchia canterburyana* transplanted and replaced by *Ceroxylon andicola*. *Phytelephas macrocarpa* removed and replaced by *Attalea Cohune*. *Areca alba* cut down and replaced by "*Euterpe pisisera*."

The number of species and varieties of Ferns in the Royal Gardens is now upwards of one thousand.

INDIA RUBBER.—On the 14th of June of last year Mr. H. A. Wickham, a resident on the Amazons, who had been commissioned by the India office to collect seeds of the *Hevea brasiliensis*, arrived in England with 70,000, obtained on the Rio Tapajos. In consequence of their retaining vitality for but a very short period they were all sown the day after arrival, and, although not contained in pans, covered a space of over 300 square feet closely packed together. About 3½ per cent. germinated, some as early as the fourth day after sowing, and many in a few days reached a height of 18 inches. Upwards of 1900 plants were transmitted August 12th in thirty-eight Wardian cases made specially to accommodate the rapid growth of the seedlings, to Ceylon under charge of a gardener.

Of the whole consignment 90 per cent. of the plants reached Dr. Thwaites in excellent condition, and they will remain in Ceylon for the present under an arrangement which I suggested between the Indian and Colonial offices, that the young plants which could not thrive in the climate of Calcutta or any of the more accessible gardens of continental India, should be nursed and established in Ceylon for subsequent transmission through the Indian gardens of Assam, Burma, and other hot damp provinces of India proper.

TEA.—The establishment of Tea plantations in Ceylon, which date from about 1868, to which I alluded in my report for 1873, is now a proved success. Samples communicated to Kew have been pronounced by experienced brokers as of very excellent quality.

THALICTRUMS FOR MIXING WITH CUT FLOWERS.

PERHAPS there is no greenery so acceptable for making up nosegays, or for mixing with cut flowers generally, as Maiden-hair Ferns. There are, however, many who do not possess the means of growing these Ferns, but who are much in the habit of arranging flowers in nosegays and glasses; and to them I would strongly recommend the growth of a few *Thalictiums*, the foliage of which in appearance very much resembles *Adiantum cuneatum*, commonly known as the Maiden-hair Fern.

Thalictum adiantiforme being probably the most elegant of the genus, I place it first. It is a distinct and lovely species, the foliage of which has a striking resemblance to the Maiden-hair Ferns. It is a lovely border or rockwork plant, and is most elegant for mixing with cut flowers. *T. adiantiforme glaucum* is in all respects similar to the preceding except in the colour of its leaves, which are of a glaucous green; and owing to the variety of colour which it gives, it is very effective for decorative purposes. *T. minus* is a very neat and distinct variety, which, from the neatness and compactness of its foliage, is sweetly pretty when mixed with cut flowers in small glasses or nosegays. These are perfectly hardy plants, and no one who can possess them need ever be at a loss for good substitutes for *Adiantum* fronds for mixing with flowers.—T. M. (in *The Gardener*).

OBSERVING INJURIOUS INSECTS.

SOME reference has been already made in these pages to a small pamphlet entitled "Notes for Observations of Injurious Insects," and which, though prepared by its author with a more immediate bearing on agriculture, stands also in close relation to horticulture. As an entomologist I wish to offer a few remarks upon it, though not in any spirit of carping criticism. I quite endorse all that is said on the desirableness of obtaining regular observations on the appearances and habits of destructive insects from every county throughout these islands. Such observations might be made by farmers, gardeners, and naturalists with far less trouble and expense than meteorological observations, and I suppose they would be quite as valuable. Also the statement is highly important that amongst the particulars to be noted those chiefly to be attended to are the "presence of surroundings," the "agricultural [and geological?] conditions," and the "state of the weather." So much for the outset, and then follows a brief description of sixteen insects, singled out from their brethren either, as most would assume, because they are offenders of the deepest dye, or else, perhaps, because they are more easily observed than are others. It is said in the pamphlet that these are "selected for observation," and though it may be esteemed desirable to have a summarised list of injurious insects, especially of those which frequent gardens as well as fields, we have no right to quarrel with a special list provided it is well drawn up.

But—there's the rub—I do not consider this list is by any means a happy selection considered either in regard to its insertions or its omissions; in the case of the latter, doubtless the author of the "Notes" could give his reasons why he has passed by some species which really need attentive observation, and which are sufficiently conspicuous for anyone to take notes as to their economy. It seems odd to have no mention of such destructive beetles as are those of the genus *Otiorhynchus*, or that widely-distributed nuisance of spring the *Aphrophora spumaria*; and aphides, we all know, are troublesome to the farmer as well as the gardener. Or, taking the order *Lepidoptera*, we might ask why such species as *Cheimatobia brumata*, *Triphæna pronuba*, or *Plusia gamma* should not be

specified? In fact, instead of sixteen one could easily make out a "century" of injurious insects, and leave many species not included therein.

Examining, however, the particular species which are actually contained in this list, we find merely a sentence is given to a passing mention of *Agrotis segetum*, but it is not numbered amongst the sixteen, though the ravenous caterpillars of this and of some allied species are every year caught in the act of depredation, and they furnish good scope for observation, for surface or root-feeding caterpillars are ticklish to deal with. Leaving out of our calculation three species named as important enemies of our corn crops, we have thirteen left in which we may be supposed to be interested as horticulturists. Nothing need be said against the mention of *Haltica nemorum*, *Anthonomyia ceparum*, *Psila Roseæ*, *Mamestra Brassicæ*, *Pieris Brassicæ*, *Agrotis obscurus*, *Tephrites inopordinis*, and *Athalia spinarum*, though in naming some of these, closely connected species might have been referred to; as, for instance, with *M. Brassicæ*, *M. Persicaria* also. Besides the moth just named only one more is specified—*Abrazas Grossulariata*, which certainly commits damage in gardens (it appears, however, to infest Gooseberries and Currants less commonly when they are grown in open places at some distance apart), yet on the whole I believe it is less harmful than the Gooseberry Sawfly. The four insects yet to be named should not, I think, have been placed on the list at all. The first of these is *Sirex gigas*, which certainly attacks the Fir in its larval state, but has nothing to do with our food crops. The second, *Asilus Crabroniformis*, is a species decidedly beneficial, so far as we know it, for the imago preys on smaller flies, and the larva, though presumed to be a subterranean feeder, is not suspected of attacking cultivated plants. *Colias Edusa*, the "Clouded Yellow" Butterfly, breeds in Clover fields; but neither in England nor on the Continent has it ever been sufficiently numerous to do any perceptible damage. Lastly, *Neuroterus lenticularis* is added, and it is almost laughable to speak of this as a hurtful species, for it can only be accused of disfiguring leaves, chiefly those of the Oak, by producing the scarlet disks with which we are all familiar. Still, if it has defects, I also admit this list is likely to do good by promoting regular inquiry into the habits of field or garden insects.—J. R. S. C.

OUR BORDER FLOWERS—LOOSESTRFES.

THE common name was given to this family from the quality absurdly ascribed to it by the ancients of quieting restive oxen when put upon their yokes. Linnæus tells us that it was botanically named after King Lysimachus of Sicily, who first used it.

The species of *Lysimachia* are not very numerous, but of late years we have had some additions, yet we seldom meet with many of them in cultivation. They may not, in the estimation of the casual observer, have the attractive properties that some of our border flowers possess, but to those interested in the cultivation of herbaceous plants they have their charms. They are a widely distributed family, especially *Lysimachia vulgaris*, which is not only found wild in many places in our own land, but in other countries too. It is quite a sight to see this occupant of moist places by the sides of ditches and streams in some of the northern counties in the late months of summer, lifting its large panicles of pretty yellow flowers above the hedges. It is a fine plant for affording cut flowers, which keep long in beauty. When once established it is not easy to eradicate, having underground stems. It is a strong grower, and is not particular as to soil or situation; a fine plant for waste out-of-the-way places. *Lysimachia clethroides* is a fine border plant, having pretty white flowers. It is of pleasing habit, and only needs to be seen to be appreciated. *Lysimachia Nummularia*, our own Creeping Jenny, and its golden descendant are charming plants for rockeries or moist places in partial shade; they are useful too for vase or basket decoration, and for planting near the margin of ponds and in damp places. Their beautiful yellow flowers have the appearance of a sheet of gold. *L. thysiflora* should have a corner near every lake and pond. If not so beautiful as some others, its rarity as a native plant claims for it a place in our estimation. When seen in masses it is very attractive. It requires time and care to get it established, and then leaving alone. *Lysimachia punctata*, a showy border flower, ought to be much more cultivated than it is. It is one of the tallest of the race, and makes a fine display when well established. *L. Ephemerum*, one of the choicest of the family, is a grand plant, having

white flowers and pleasing habit—an acquisition, and useful for exhibition. *L. ciliata*, *stricta*, *verticillata*, *quadrifolia*, and others that might be named are all useful for shrubbery and out-of-the-way places, and will flourish wherever they can obtain light, air, and moisture. They are easily increased by division when growth has commenced in spring.—*VERITAS*.

PORTRAITS OF PLANTS, FLOWERS, AND FRUITS.

DYCKIA FRIGIDA. *Nat. ord.*, Bromeliaceæ. *Linn.*, Hexandria Trigynia.—“The species of *Dyckia* are mostly Brazilian, and some of them come from the colder southern provinces. This is probably the case with the accompanying plant, which flowered freely in the cool half of the succulent house at Kew in February of the present year, and is now maturing its capsules. It was received from Messrs. Linden under the name of *Pourretia frigida*.”—(*Bot. Mag.*, t. 6294.)

TIGRIDIA LUTEA. *Nat. ord.*, Iridaceæ. *Linn.*, Monadelphia Triandria.—“It was named and well figured by Link, Klotzsch, and Otto, from a specimen sent to the Berlin Botanic Garden, from the island of Chiloe, by Professor Philippi in 1840. It is the only species of *Tigridia* that comes from that part of the world, all the other five that are known being Mexican. The present drawing was made from a plant that flowered with Mr. H. J. Elwes at Cirencester in the autumn of 1876.”—(*Ibid.*, t. 6295.)

CYPRIPEDIUM HAYNALDIANUM. *Nat. ord.*, Orchidaceæ. *Linn.*, Gynandria Diandria.—Native of the Philippine Islands. Greenish white, blotched with dark brown. It flowered in February at Messrs. Veitch's, Chelsea. “It is named after his Excellency Dr. Ludwig Haynald, Archbishop of Kalocsa in Hungary, whom Dr. Reichenbach justly commemorates as a zealous botanist and an active promoter of science and art, and whose name will ever be most honourably connected with the development of Hungary.”—(*Ibid.*, t. 6296.)

XANTHORRHEA MINOR. *Nat. ord.*, Juncæ. *Linn.*, Hexandria Monogynia.—“We have native specimens (gathered by myself in company with Mr. Gunn), on Grass Tree Hill, near Hobart, and others from Victoria; whilst the much larger form abounds near York Town, Tasmania, where, according to Gunn, it covers hundreds of acres, to the exclusion of almost every other plant. In December, 1841, Mr. Gunn describes the country as being white with it, one plant producing thirty-six flowering scapes, whereas in the following year he could get only six or eight specimens in flower on the same spot. From this he assumes that the *Xanthorrhoea* do not flower every year. The copiously-flowering one may be that alluded to by Mueller (Fragments, iv. 112), as possibly distinguishable from *X. minor*, and if so to be called *X. polystachya*.

“*X. minor* was sent to Kew some years ago by Baron von Müller from the rich collections of the Melbourne Botanic Gardens, of which he was the Director, and it flowered in February of this year; its flowering season in Australia being December and January.”—(*Ibid.*, t. 6297.)

GLOBBA SCHOMBURGKII. *Nat. ord.*, Zinziberaceæ. *Linn.*, Monandria Monogynia.—“*Globba Schomburgkii* was discovered by the late Sir Robert Schomburgk when H.B.M.'s Consul at Siam, who sent roots to Kew in 1864, where it has flowered repeatedly in August. It has been distributed as *G. bulbifera*, *Roxb.*, from which and from all others it differs in the curious panicles.”—(*Ibid.*, t. 6298.)

PREMIER PEACH.—“This fine Peach was raised a few years ago in the Royal Gardens at Frogmore, and is the result of a cross between the *Grosse Mignonne* and *Bellegarde*. In general appearance it much resembles the latter variety. The fruit is large, round, and of even outline, with a slight suture extending generally to the apex; the skin is purplish red, becoming very dark when fully exposed to the sun, and often having spots and blotches of dark red on the shady side and near the base. The flesh is tender, juicy, and melting, with a delicious flavour; and the flesh parts freely from the stone. This variety truly deserves a place in every garden where Peaches are grown on the open wall, on account of its hardiness, healthy habit, and the good quality of its fruit. Mildew never attacks it, and it is generally free from the other ills to which Peach trees are subject.”—(*Florist and Pomologist*, n.s., x., 97.)

NOTES ON VILLA AND SUBURBAN GARDENING.

FRUIT TREES of all kinds are this season making free growth, and the great difficulty will now be to have such growth fully ripened; therefore continue to train and nail-in the young wood

of wall trees, but let all superfluous growths be removed. As a rule the shoots should be trained sufficiently thinly that the foliage of one branch does not overlap that of the next. The stopping of pyramids and bush trees should be finished forthwith. It will not be necessary to give any advice towards the thinning of stone fruits, as in very few cases are there sufficient to half recoup the labour expended upon them. Apples are more plentiful than most other kinds of fruit, and go where you will in Surrey the same complaint is heard—no Pears, Plums, or Cherries on the bush trees, and very few Peaches and Nectarines on the walls. Under these circumstances Grapes and Melons will be the more valuable, and it will be well to secure late crops of the latter.

Strawberries have now in most cases ceased bearing; the laying of runners in pots for forcing or for renewing future plantations must receive immediate attention. The late showery weather has been favourable to the growth of runners, and the earlier these are planted in their new situations the better, as the stronger the plants become before winter the more fruit may they be expected to bear next season. In very few instances will plantations remain in health and vigour many years, consequently periodical renewal of plantations is absolutely necessary; and though the Strawberry may be considered a surface-rooting plant, not one delights more in deeply-trenched and well-manured ground. In making a selection of kinds it is well to remember that some sorts flourish and fruit well on some soils, whereas on other soils they will do no good; but the following kinds do well in most situations: Keens' Seedling and Vicomtesse Hericart de Thury for the earliest crops, the first a good-flavoured and early Strawberry, the latter a good grower and prolific bearer. President, a good-looking and free-bearing Strawberry, which ought to be in every collection. No Strawberry stands more highly in popular favour than President. Sir Harry, a good old kind, and as Mr. Baker grows it at Coombe Cottage it cannot be excelled. Mr. Baker says there are spurious sorts of Sir Harry sent out. Dr. Hogg is a good and useful Strawberry, but does not succeed in all situations. Lucas, James Veitch, and Her Majesty are good sorts, and have much to recommend them both for cropping and the large size of the fruit. Her Majesty, as shown by Mr. Jordan at Wimbledon this season, was one of the largest Strawberries we have ever seen, and he speaks highly of it. Where a late kind is desired there is none to excel the Elton Pine.

Roses require frequent attention to keep them orderly, taking off all suckers and fading flowers as they appear, and running the hoe frequently through the soil after rains, not only to keep down weeds but to give an air of finish and tidiness to the beds. The Rose is indeed an amateur's plant, none more so. No garden however small is without a Rose, and its cultivation is a source of delight. Budding should now be accomplished as rapidly as possible. The first batch of Roses are over, and there are therefore plenty of buds to choose from. The weather has been everything that could be desired, so that the stocks will be found in good condition at the present time. In selecting the buds take those that are plump and firm. Full directions for budding were given with cuts (which will do more to help beginners than a page that could be written on the subject) in the number for July 5th, page 12.

Camellias, Azaleas, Ericas, Epacrises, Acacias, Cytisus, Coronillas, and all other hardwooded greenhouse plants are benefited by being placed out of doors on a bed of ashes or on slates or tiles. A north-west position should be selected if possible. The wood then becomes gradually ripe and firm, which not only causes them to set their blooms the better, but is a great preventive of mildew, red spider, and other enemies. Watering such plants frequently overhead after warm days does much good, but at the same time see that they have free drainage, for very few continue healthy if water stagnates about their roots. Late-blooming plants of *Aphelexis* and *Dracophyllum gracile* are the better for having their blooms cut off, pruning them down to where they commence new growths. Cuttings of *Kalosanthes* now strike very freely and make useful decorative plants. *Pelargonium* which have ripened their wood should be cut down, and the cuttings inserted in small pots or in the open ground; they make useful plants by next spring. As the houses become emptied of their contents it is a good time for cleaning and repairing. Paint if applied now will become hardened and sweet by the time the plants are placed in the houses for the winter. Cleanliness, plenty of water, and moderate shading are the chief wants of plants during summer.

In the kitchen garden all kinds of the Cabbage family may be planted, if not already done, for winter supply. As early Potatoes are lifted successive crops of Turnips, Coleworts, Cabbage, &c., must be planted to fill up the ground. The main crop of Endive may now be sown. The Broad-leaved kind is useful during winter months as a culinary vegetable. Fraser's Improved Broad-leaved and Batavian are good sorts for this purpose, but the Moss and Green-curbed are most sought after for salads. Sowings of Lettuce should also be made, which will help to carry on the supply until Christmas. Hicks' Hardy

White and the Brown Cos are useful sorts of the Cos varieties, and the All the Year Round of the Cabbage varieties. The ground between the Celery trenches is an admirable place to perfect their growth.—J. W. MOORMAN.

DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

HARDY FRUIT GARDEN.

THIS is the best time to propagate by budding those trees that are best increased in that way, the most prominent being Peaches, Nectarines, Plums, Cherries, Apricots, and Pears on the Quince. The buds inserted on the Quince stock should be near the surface of the ground, in order that when the trees are planted or potted to form orchard-house trees the union may just be covered with soil. In respect of the others named this is immaterial, as the trees can either be treated to produce dwarfs or standards of any height. It is best to choose strong fairly-matured young wood from which to take the buds; of the Peach and Nectarine, which bear only on the young wood of the previous year, there is considerable difficulty in procuring buds, as those only can be used that are in triplets. The middle bud will produce a shoot and the side buds blossoms. All single buds are blossom buds. As detailed and illustrated articles have so recently appeared in this Journal on budding Roses, and as the method of budding fruit trees is similar, there is no need to say any more about it here. In three weeks after the operation has been performed it is well to look over the work and loosen the bandage. Those buds of which the bark is fresh and green have taken; the shrivelled and black buds are dead, and a fresh one may be inserted in another part of the stock. If the stocks are very dry at the roots it will be necessary to give them a considerable supply of water, else the bark will not separate freely from the wood, and if it will not do this successful budding is impossible.

Vines on walls now require to be carefully looked over and to have all lateral and unnecessary growths removed. If the Vines are crowded with young wood success can no more be looked for on walls than in vineries mismanaged on the same principle. The Vines which succeed best cultivated on walls—viz., the Royal Muscadine and White Sweetwater, produce the finest flavoured fruit when it is exposed to light and the influence of the sun's rays. Black Hamburgh succeeds well on walls in favourable positions in the south of England, but the fruit must not be so freely exposed as that of the white varieties. The shoots should be laid-in securely and regularly over the walls, and when this is the case a very pleasing effect is produced. To be successful with the Sweetwater and Muscadine a supply of strong young growths must be produced annually from the base. The spurs do not produce well after the third year. We would not have them more than two years old, especially if the walls are under 9 feet in height. We need not say anything about thinning-out the fruit this year, at least no one in this district requires information about it.

Cherries have been a most abundant crop, and indeed all small fruits. Our wall trees have been looked over some time ago, but those who have not yet stopped the laterals and laid-in the young wood should lose no time in doing so. The trees will grow the more freely the less fruit they produce. See that all insect pests are destroyed if possible as soon as they appear.

PINE HOUSES.

The plants have been examined in all the houses, beginning with the fruiting house, where a large proportion of the fruit had been cleared off. The plants were furnished with some strong suckers; these were taken off close to the old stem, and have been potted in 7-inch pots, using good sound loam five parts, one part of decayed manure, and a little charcoal broken into pieces the size of a walnut. The pots are well drained, and a little fibre placed over the potsherds prevents the compost from mixing with them. When potted we plunge the pots to within an inch of the rim in a bed of tan fresh out of the tan-pits; this will raise the bottom heat to about 90° or 100°. The old plants were thrown out, and all those on which the fruit had not yet ripened were placed together at one end of the bed. The plants intended to fruit next summer have been removed to the fruiting house, and the pots also plunged in a bed of fresh tan. They are not nearly so strong as we have had them, but the leaves are broad, short, and well browned. We have seen immensely strong plants that had been grown in a close moist atmosphere, and although they gave promise to produce great results they did not come up to expectation. The Pine houses ought to be well supplied with fresh air and the plants be freely exposed to the sun, maintaining at the same time a sufficiently high temperature. Pine plants if kept in conditions conducive to vigorous health are seldom attacked either by scale or mealy bug; but a careful look-out must be kept for these pests.

GREENHOUSE AND CONSERVATORY.

Where there is a large collection of hardwooded plants some-

thing will always be required to be done. Tying-out the young growths, watching the plants for red spider, green fly, and scale, and during hot dry weather attending to watering them, will give ample pleasant employment to the ardent cultivator. Nor will he allow any plants to suffer for want of repotting at the proper time. One of the most useful plants is the *Statiche profusa*. Ours were attacked by mildew, red spider, and green fly at one time. We did not try any patent washes for them, but made a solution of soapy water as strong as the leaves would bear, and added a good proportion of flowers of sulphur. The plants were held over a water-carrier in order to save the water, which was applied again and again with the syringe until every part of the leaves was well wetted; the effect of this being to thoroughly cleanse the plants from all their enemies.

Stage *Pelargoniums* are still furnished with some fresh trusses of finely developed flowers. Those that are faded are removed at frequent intervals, so that the house is kept tidy. The earliest plants are removed out of doors and do not receive a very large supply of water at the roots; and as soon as the wood is ripened the plants are cut down, but before doing this the soil in the pots is allowed to become almost dusty dry, so that bleeding from the cuts may be prevented and the wounds may heal more readily.

Fuchsias are the most useful of plants for decorative purposes to succeed stage *Pelargoniums*, and no garden ought to be without a selection of them. Plants raised from cuttings struck early in the spring show the most vigorous development if potted in rich soil—good turfy loam four parts, well-decayed manure, and a little bone dust and leaf soil added will make an excellent compost. The varieties now in cultivation can hardly be overgrown if the compost is not too strong for the roots, their character is so floriferous. As a rule young plants are the best for general purposes, but a few large specimens have an excellent effect arranged as a background on large stages. An excellent effect is also produced by training a single stem to the rafters of the greenhouse. At the nurseries of Mr. John Fraser, Lea Bridge Road, may be seen a number of plants trained in this way annually. He strikes the cuttings in the autumn and grows them on rapidly in such soil as has been recommended. The plants are grown in 10-inch pots, and continue producing enormous quantities of flowers all the summer and autumn. The best varieties adapted for this work are *Arabella*, *Constellation*, *Delight*, *Josephine*, *Marginata*, *Puritani*, *Lustre*, and *Snowdrop*: these are sorts with single flowers. Of double varieties there are *Alpha*, *Champion of the World*, *Diadem*, *Elegant*, *Empress*, *Harry Williams*, *La Neige*, *May Felton*, *McMahon*, *Sir Colin Campbell*, and *Tower of London*. The above sorts are recommended by Mr. Fraser for this purpose, who says that some sorts are better suited for this purpose than others.

FLORIST FLOWERS.

The Tulip roots have been lifted and stored away in a dry cool loft for the present. Each sort was lifted separately, and the roots with all offsets attached placed in a small flower pot with a label, to be attended to at a more convenient season. Tulips and Hyacinths in pots have also had the soil shaken from the bulbs, but we are not very careful about the names to these. The roots were thrown into baskets, and the best roots will be potted, the Hyacinths three in a pot, and the Tulips about six.

As the Carnations go out of bloom those plants that are in pots are placed out of doors in a position well exposed to the sun, and the grass will be layered when it is in good condition. Auriculas behind a north wall are still enjoying a quiet rest. They do not require much water at present, but they must not be allowed to become too dry at the roots, and when the sun comes round to the frames in the afternoon it will be well to throw a slight shade over the glass. As we expected, the pipings of Pinks are not striking very freely, except those that were very small and composed of the side growths. Gross succulent shoots do not root freely under any circumstances. If any varieties refuse to strike roots more suitable pipings may be obtained in a week or two.

Gladioli are very late in offering to throw up the spikes this year, the reasons being a late season, and there was no opportunity of planting any roots early owing to the continued wet and cold; but the appearance of the plants suggests that we shall have a good bloom. The surface of the beds has been mulched with manure, and they have received one good watering. Dahlias and Hollyhocks will now engage much attention. The surface of the ground must be mulched, and the plants watered if they require it. Both are gross feeders, and can take in dry weather a plentiful supply of manure water.—J. DOUGLAS.

TO CORRESPONDENTS.

* * All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

RATING HORTICULTURAL STRUCTURES (J. W. W.).—They are not exempt from the supervision of the Local Board. If the buildings are rated your appeal is to the Quarter Sessions.

WHITE MARTAGON (Mrs. J. N.).—A similar flower was exhibited by Mr. G. F. Wilson at the Royal Horticultural Society on the 17th inst. He called it Martagon album.

BEGONIA LEAVES INSECT-EATEN (Mrs. L.).—Look for the marauder with the aid of a candle at night. The injury is probably caused by a night-feding weevil.

LAUREL LEAVES (M. W. Cork).—They are perforated by some weevil, not by the Acari you enclosed. We can only suggest placing a sheet beneath the bushes, shaking these and destroying the insects which fall upon it. The *Gloxinias* require more heat, and the *Capsicum* better culture. The deficiency we cannot surmise.

BRIAR STOCKS (Paddle).—Plant young shoots as early as possible, and leave the old Briars where they are. They would be grand stocks in two years' time, and quite fit for budding Teas on in one year. October is the best month for inserting them, and a single wild Briar will furnish often five or six shoots.—WILD SAVAGE.

STOCKS, WALLFLOWERS, AND CARNATIONS (Amateur).—You have manured them too liberally whilst they were young, so that they have produced leaves only. They are over-luxuriant.

PRIMULA SEEDLINGS (E. R.).—Pull off the seed skin which remains on the cotyledon leaves.

AIR-TIGHT VINERY (A. Boyle).—"OBSERVER" informs us that the Grapes grown in the air-tight vinery "are not thick-skinned, neither deficient in flavour or poor in colour. He also states that the building is cheaply constructed by having all the woodwork prepared at saw mills, as it is chiefly composed of grooved rafters. A pattern rafter is sent to the mills, where any quantity like it can be obtained at one-third less than if cut-out by hand.

BLACK HAMBURG GRAPES NOT COLOURING (J. D.).—The defect is probably caused by the crop being too large and the roots not being supplied with sufficient water and a little liquid manure.

CUCUMBERS WITHERING (J. H.).—It probably arises from defective root-action. Apply a little weak liquid manure and thin the fruit severely. You have allowed too many to remain on the plants.

SAVOYS AND BROCCOLIS BOLTING (Dan).—This and the clubbing was occasioned probably by the supply of water to the roots being deficient.

EARLY BEATRICE AND EARLY LOUISE PEACHES (E. D. L.).—They are medium-sized fruits about 2½ inches in diameter. They are not liable to crack if grown in a favourable temperature and moisture.

BANKSIAN ROSE NOT FLOWERING (H. J.).—Throw away your pruning knife and you will have a profusion of bloom in a year or two. At any rate avoid any attempt at scientific pruning in your treatment of this Rose, for it is upon that rough twiggy growth that the flowers appear in full abundance, and as this when left on has an unkempt untidy air, you have probably diligently removed it in the thinning-out process which you describe. In the south of France, where this Rose is left to ramble over arbours, old trees, or any rough surface, it is never pruned, and soon forms dense thickets, which are a perfect cloud of bloom in the flowering season.

SEEDLING PELARGONIUMS (C. Neilson).—You incur a fruitless expense in sending the flowers. The petals are shed, and we can only say they seem handsome, but not superior to many of the legions of varieties to be purchased at the florists.

ROSE (W. Wallace).—We believe it to be *Niphetos*. You must write to Mr. Pearson for the cutting you name.

DOUBLE TEN-WEEK STOCK (A Constant Reader).—The specimen is very good, and we have no doubt the robustness is due to the use of manure water. No one can identify a Rose from a single bloom, the varieties are a legion. Where properly supplied with manure and water *Chrysanthemums* are looking very well.

TULIP TREE (A. Lighton).—It is the *Liriodendron Tulipifera*, a hardy tree, native of North America. It is not uncommon. There is a fine specimen in Kensington Gardens.

ROSE LEAVES (M.P.).—The brown blotches on the leaves indicate that the roots have not had a sufficient supply of either manure or water, or both.

BEGONIAS (Inquirer).—The flowers are good but not superior to many others well known. The silver variegation of the leaves we do not think can be an improvement.

STRAWBERRIES (W. J. M.).—Dr. Hogg is superior to British Queen on some soils; three other excellent kinds are Sir C. Napier, La Grosse Sucrée, and Frogmore Late Pine. Waste neither time nor space upon barren Strawberry plant, but destroy those which were planted in 1875 and are still unfruitful, and replace them with runners taken from plants that are actually fruiting well now. Strawberries should be watered freely in dry weather, during the season of growth and fruiting.

HEATING AND PLANTING A VINERY (A. S.).—You deserve success, and we congratulate you on your industry in having made with your own hands during morning and evening hours a span-roofed vinery 20 feet long, 11 feet wide, and 11 feet high, finished so well as is shown in the sketch you have forwarded to us. We doubt, however, if you will have sufficient top ventilation during a hot summer; but you can easily supply the deficiency, if it is a deficiency, by removing, if required, a square of glass from each end of the house next the apex. We think your mode of making the house portable is good. Such a stove as the one to which you refer would not be sufficient to exclude frost from your house. With two of the stoves you would be safe, and you would not have any difficulty with the down draught. We do not approve of the earthenware flue. We have seen one formed 100 feet in length which had to be removed on account of the pipes cracking. If you can incur the expense of a boiler and hot-water pipes adopt that mode of heating; if not, try the stoves. Your "practical hot-water friend" will probably give you good advice. You can fix the pipes yourself with indiarubber

rings, and so render them portable. It is not imperative that you heat the house this year, or until you obtain plants as well as Vines. If your inside border is good, and you support the Vines well by giving sufficient water, your mode of planting five Vines on each side of the house would give you the quickest return of fruit; or, as the roof is not lengthy, three Vines on each side, taking up two canes from each, would probably answer as well. But as amateurs sometimes fail with Vines wholly in inside borders, we should also plant two Vines at the end where you say "the roots could grow outside as well as inside." If these Vines are found to thrive the better—which is probable if the natural soil of the garden is good—we should grow them on the extension system, removing the others as the space is required for the permanent canes. The supernumeraries—the inside Vines, would more than pay for their cost and keep if fairly well managed. Plant the permanent Vines at the corners of the house, and let them grow in a free upright position during the first season. In the winter cut them down to the base of the rafter—the corners of the house, or if very strong they may extend 2 feet from the ends, from whence the first upright cane must be taken, the terminal eye being also encouraged for extension, the cane which it forms being pruned in the winter near the point where you desire the next rod to issue. Continue that practice until your house is filled, training the rods of your permanent Vines between the supernumeraries, which should be at 3½ feet apart. The terminal shoots of your permanent Vines should be permitted to grow in an oblique direction during the summer, depressing the canes at the winter pruning. The subsidiary Vines need not be pruned so closely, your object with them being to obtain fruit as quickly as possible, but do not permit their foliage to shade the leaves of the extension Vines. Do not have the wires nearer to the glass than 16 inches. The best Grape for your purpose is the Black Hamburgh, but if you desire white Grapes you might plant a Vine each of Foster's Seeding and Buckland Sweetwater.

HEATING VINERY AND GREENHOUSE (—).—Unless your vinery is very wide and lofty you will not require pipes all round the house just to keep frost out. A 4-inch flow pipe from the north-west corner to the south-east corner, and a return pipe underneath the flow, conducting back to the boiler, will afford you security from frost. We do not see how you can arrange the pipes except by having a trench in the floor and a cast-iron grating for covering it. If the pipes were not considered objectionable if placed on the floor at the front of the west-end border and rockery, there is still the difficulty of the outer doorway at the west end of the house. You must either cut the cement floor and place the pipes in a trench as suggested, or submit to the inconvenience of their crossing the doorway and conducting them above ground as far as the dining-room door (not across it) and back to the boiler.

TRAINING PEAR TREES (J. E.).—We do not consider your plan a good one, for the simple reason that eventually when the tree reaches its limits of space an excess of vigour will soon be developed in the upper portion at the expense of the lower part. The very best method of training the Pear on walls and as espaliers is that form which was originated by the French, and by them termed *Palmette verrier*, and which is simply an improvement of the old horizontal espalier, each branch being trained horizontally for a certain distance, and then turned upwards and continued to the top, so that the end of every branch is upon a common level at the top instead of at the sides of the tree as used to be the case, thus securing that important object, an equal distribution of vigour in every part of the tree.

STRAWBERRIES AND SLEGS (S. E. W.).—Quicklime spread between the rows when the Strawberries are ripening is an effectual protection. It requires repeating if rain occurs. Strawberries, we may add, are seldom injured by slugs if cut straw—that is, straw cut into lengths of about an inch, is spread over the surface of the ground to keep the fruit clean. For the aphid mixture try the different strengths and use that you find most effectual. We find a quarter of a pound of quassia chips to four gallons of water sufficient. Do not omit the soft soap; it will not injure the Rose buds, and may be syringed off or removed by the first rainfall.

VEGETABLE MARROWS NOT SWELLING (A. M.).—The most general cause is want of moisture; but in your case we think over-rich soil, inducing undue luxuriance, is the most likely cause. Instead of cutting off any leaves we should thin out the shoots and allow the plants to grow as will, not limiting them as to space, and we think you will have fruit abundantly. Apply water only during dry hot weather.

MILDEW ON ROSES (Alfred).—Mildew, and aphides, and red fungus, and all other ills which Roses are liable to arise from check, and this may be caused either by severe weather, drought, or an exposed situation. Where Roses are in a good state of health and growing freely it is quite exceptional to see any of these drawbacks. In Mr. Baker's rosery at Heavitree are about four thousand Manetti Roses growing 3 feet high with the greatest luxuriance, and no signs of mildew or blight of any kind. The remedies for mildew are so numerous that it is a difficult matter to recommend any one. Try dusting the leaves with soot, leaving it there for a day and then washing it off. Soft soap can be applied with a brush, and will also answer your purpose.

BUDDING MANETTI STOCKS (Idem).—The stocks being in rows earthed-up like Potatoes, take a hoe or spud and remove the earth from the stock, so as to insert the bud as low as possible. When this is done proceed to cut the bud just the same as you do for the Briars, and make an incision as low down as you possibly can; the lower down the better, as the fewer will be the suckers. Indeed you should almost bud on the roots if possible, at any rate strive to insert the buds as low as you can. Only insert one bud in each stock. Choose the same side of the stock all down the line, and also select a place as free from knots or irregularities as you can find. Make the incision in the form of a T, and when the bud is safely in tie up well beyond each end of the bud with rough cotton or worsted. Ladies often use wool, and nurserymen bass or roffia or cotton. You must not replace the earth, but leave the bud showing, or rather the cotton, so that in the course of a week you can see whether the bud has taken or not. If it has not, bud the other side of the stock. Do not touch the Manetti shoots, but leave them to grow as luxuriantly as they will till the following spring, then remove the cotton and cut back the Manetti to the bud. The best time for budding the Manetti is after rain, and if you have no rain give the stocks a copious watering and you will find the bark run. August is the best time for budding Manettis. All the kinds you have named do well on the Manetti; in fact all Hybrid Perpetuals except La France, which, having some Tea blood, never does so well on this stock as on the Briar.

CLIPPING EVERGREENS (S.).—The evergreens being in good form, the best time to clip them is early in August, but the shears must only be applied to such subjects as Yew. Common and Portugal Laurel should only have irregularities of growth removed with a knife or scissors, the scissor being the most handy implement; and in cutting-in care must be taken to leave some

leaves of the current year's growth. If the evergreens are overgrown and require cutting-back severely the best time to perform the operation is during moist mild weather at the close of March or early in April, at which time you may cut them back to any extent, shortening any irregularities of growth in August.

TRANSPLANTING EVERGREENS (*Idem*).—Late in September if the weather is moist and until the middle of November, and from the middle of February until the middle of April, are the times we have been most successful with evergreen removals. Hemlock Spruce may be moved at the same time. It is a very graceful tree, but requiring shelter and a moist situation, doing fairly well in moderate shade.

KLEINIA REPENS.—"J. B." wishes to know where it can be obtained.

APPLYING LIQUID MANURE TO VINES (*J. W. L.*).—When the Grapes are swelling liquid manure does most good, and as a general rule that is the best time to give the border a thorough drenching with it; but if the drainage is defective all due caution must be taken not to overwater, or shanking will inevitably follow. As you manured the border last winter no doubt the rain water has conveyed much nutriment down to the roots; but as the crop is heavy do not hesitate to pour on sewage if the drainage is sound, for there can be no question that it will be beneficial to the Vines, promoting both the swelling of the fruit and a strong wood-growth for the next season. We congratulate you on your successful management of such old Vines.

BRIAR STOCKS FOR ROSES (*G. C. A.*).—Stocks of the Dog Rose should be procured in autumn, towards the month of November, for ordinary soils; but if to be planted in wet ground the spring is preferable. The most advantageous plants for stocks are those two or three years old, about the thickness of the thumb, the bark of which is either of a smooth grey or grey striped with green. The stock should be long, straight, and with a good root. Before planting, all the old decayed roots should be carefully trimmed off, as well as all superfluous knots or branches. If a saw is applied for this purpose the wounds should be closed up with the pruning knife and the cicatrises covered with grafting wax. The stock thus prepared of the height desired should be straight and smooth as a walking-stick. If planted in lines posts can be placed at intervals with a rail, to which each stock may be carefully attached by osier bands. This is the best mode of planting for a nursery ground.

FLAT STAGE AROUND GREENHOUSE (*Eve*).—The best description of stage for a greenhouse is one formed of laths 1½ inch wide and 1 inch thick, with one-inch space between the laths, nailed to cross pieces 3 inches by 2½, fixed 3 feet apart, one end let into the wall and the other end supported by wooden uprights 8 inches square, which should stand upon a brick or stone base slightly raised above the floor. The laths to be fixed widest side upward, and the cross pieces narrowmost; the whole to be dressed and have at least three coats of oil paint, to be thoroughly dry before the pots are placed upon the stage.

NAMES OF PLANTS (*Miss Dennis*).—*Catalpa syriacifolia*. (*R. C. C.*).—*Lonicera Ledebouri*. (*Student, Hadlow*).—We cannot name so many, nor from such imperfect specimens of weeds. (*Mrs. Holmes*).—We cannot name florists' varieties. (*Twelvemonths Subscriber*).—Your Fern is probably a species of *Acrostichum*. The Mock Orange is *Philadelphus coronarius*. (*H. N. C.*).—1, *Rhododendron ferrugineum*; 2, *Gentiana caucasicas*; 3, *G. acutifolia*; 4, *Gentiana sagittata*; 5, *Astrantia major*. (*J. W. C.*).—All forms of *Athyrium Filix-femina*. 1 and 2 appear to be the var. *Prizellae*. (*T. Perry*).—1, *Stachys sylvatica*; 2, *Centaurea nigra*; 3, *Prunella vulgaris*; 4, *Agrimonia Eupatorioides*; 5, *Hypericum pulchrum*; 6, *Crepis virens*. (*P. McDonald*).—Cannot name from specimen sent.

POULTRY, BEE, AND PIGEON CHRONICLE.

WEEDING.

It is time to begin. Probably many have been weeding their yards of wasters for some weeks past, and birds which evidently would never develop into good specimens have in many places been by now doubtless eaten. Well and good: such breeders work wisely, and by making room afford more scope and opportunity for the rest to thrive. There are, however, very many fanciers who never weed, who allow every bird they can breed to come to maturity. They cling to a false hope that a bad bird may in time make a good one, or that someone will give them 3s. or 4s. more than the table price of a bird, even though it may be a sooty-footed Dorking or a white-legged Ham-burgh, because it is reputed to be of a good strain. We beg fanciers in their own interests as well as those of the fancy in general to abstain from doing this. Annually we have a larger glut of useless birds in the market, and annually we find the prices for good specimens decrease; we do not mean of such birds as will win at Birmingham or the Palace, for those will probably always maintain their prices, but we allude to good specimens which would hold their own at country exhibitions. The rubbish we see at show after show in the sale classes, the few shillings we see charged for birds and eggs of well-known strains, the perfect trash we see at auction sale-rooms, all help to tell the story, and to show that hundreds of birds which would make wholesome and palatable food are allowed to accumulate, in the hope of selling them, until they have passed the time when they would have proved the most serviceable for home consumption. Those clinging to the hope by holding on to these wasters—badly marked, under-feathered, or faulty-clawed birds, that they may some day obtain a better market for them, do not surely realise what extra cost is entailed in the keep of those fowls. They literally eat their heads off; and when at last in a fit of despair they are sent by the owner to an auction sale the low prices they probably fetch cannot repay the price of the food that they have eaten, not to speak of the cost of carriage, entry fees, and baskets, and above all of the room they

have taken up at home which better birds should have had. This latter is a great point.

When yards are small or grass runs limited the smaller the number of birds that are retained the better will they be. Over-crowding means ruin to all. Underfeeding means the same; consequently how much better must a dozen birds progress in a small yard than a score in the same place. The breeder is indeed fortunate who has but few specimens under the mark. By careful breeding, however, after a time the number should of course be lessened, but there are very few good breeders who do not obtain some "weeds" every season. An amateur who has had any fair amount of experience should know what to kill and what to leave; and even if occasionally a mistake is made the surviving birds will be better for the extra accommodation and food. But mistakes like these seldom occur; and at any rate the veriest beginner can weed-out single-combed birds which should be double, or, *vice versa*, those with wrongly coloured legs and beaks or wry tails, and specimens with plumage which no moult can ever make right. After he has bred for a year or two his experience would be larger, and he could weed out many others which before in ignorance he allowed to live. There are plenty of beginners, we are sure, who buy the best birds they can obtain for money, who get some skilled person to mate them up for them, and yet who never come to the front in the way that they ought to do. We believe the reason is that they hatch too many for their accommodation and then do not weed them out enough. Such a plan may do very well where unlimited range can be given and the food can be supplied as liberally as it can be eaten, though even then the more the knife is used the better will the survivors be. There are, however, many who have only a piece of a garden or a tiny paddock at their disposal, but who wish to be winners and to breed exhibition chickens; were such to kill off with discretion as soon as the birds were fit to eat in any form one-half of all they bred, we feel sure they would do infinitely better with the remainder. We would not, of course, recommend amateurs to set to work slaying half their broods when they had reached a certain age just for the sake of reducing the number to make room for the others, as that would indeed be ridiculous; but when they have acquired the means of distinguishing between fair and positively indifferent birds, then they should never spare the latter.

No better time than the present is there to weed. In the interval of writing these lines we have been out to condemn two couples of chickens, and yet at many shows last year we saw worse birds than those ordered to death; but we are assured from experience and from the systematic way in which many great breeders set about it, that it is very much better for anyone who wants to establish or keep up a strain and make his poultry profitable to send out to the fancy, or allow visitors to inspect only half a score of well-conditioned and well-grown than two hundred indifferent birds. As we said before, now is the time to set to work, for most chickens by this time have come to the age when merit can be determined upon; and in all good faith we believe that those who weed freely now and in the weeks which are coming on will have eventually much to be grateful for, by obtaining better-grown specimens, and consequently better prizes or better prices.—W.

WHICH IS THE MOST PROFITABLE BREED OF FOWLS?

It is manifest that we must choose one of those breeds whose mission in life is apparently to produce eggs at their master's pleasure, and from whom human art and skill have taken away the natural desire of sitting. A tabulated form, in which is a scale of the merits and demerits of each breed, will probably show in the simplest manner an answer to the question. Take the following breeds as the representatives of the non-sitting class:—

	Egg-producing.	Hardiness.	Quality of Flesh.	Size of Egg.	Total.
Spanish.....	5 .. 2 ..	3 ..	1 ..	1 ..	9
Leghorns	2 .. 1 ..	3 ..	2 ..	2 ..	8
Hamburghs, Spangled ..	2 .. 2 ..	2 ..	2 ..	2 ..	8
" Pencilled ..	1 .. 3 ..	2 ..	3 ..	2 ..	9
" Black	2 .. 2 ..	1 ..	2 ..	2 ..	7
Minorcas	2 .. 1 ..	1 ..	1 ..	1 ..	5

There is so little difference in these six leading varieties of layers that there is no necessity for a wider variation of the scale in the above table. The figure 1 will represent the highest excellence in each characteristic, the figure 3 the lowest. Of course there is wide room for difference of opinion as to the merits of the various breeds specified, but the general experience of the writer is in accordance with the table—the Pencilled Ham-burgh ranking first as a layer, but last in size of the egg and in hardiness; the Spangled Ham-burgh being equal to the Black except in the quality of flesh; the Leghorn being the equal of the Spanish in this last characteristic; the Minorca scaling the highest in all points except that of laying, and being equal to the Leghorn in hardiness. All being unreliable and almost worthless as sitters, no comparison is made between

them in this respect. The Polish, being but indifferent layers in winter, as a rule—to which, however, there are many exceptions—have been omitted from the above list.—G. H. C. (in *Pet Stock Bulletin*).

CLECKHEATON SHOW OF POULTRY, &c.

THE annual Show took place at Cleckheaton on the 21st inst. in grounds much better adapted to the purpose than have been used by this Society previously; the entries in poultry, Pigeons, and Rabbits were 230, the poultry coming up least in numbers.

Game were but a moderate lot and correctly placed, as also the larger varieties of poultry, except that we thought pen 4 in *Brahmas* ought to have displaced some other. *Hamburghs* were good and correctly judged throughout, as also the *Bantams* in all classes, which were certainly about the best section; the rest of the poultry classes proving of no special interest.

Pigeons a better entry than poultry. Carriers were first on the list; the first a well-shown Black cock; the second not so good as pen 5 (Mawson), highly commended, which is much larger in neck and better in beak wattle. Pouters, first Blue and second Black, two good birds; and a Red highly commended. In Tumblers the winners were both Almonds; the first, a cock, was not nearly so good as the second hen, which is broader in skull, higher in stop, and altogether a better class of bird. Fantails were good and well placed. Dragons, the winners Blue; the first too flat on skull and fleshy-eyed; the second altogether a better bird and much harder in cere. In Jacobins also we considered the award a great mistake, the second leading in all Jacobin points, being larger in hood, chain, and feather generally than the first. Turbits, first Blue and second Red, and well selected, as also the Antwerps, which were very good in both Long and Short-faces.

In *Rabbits* were some good specimens, but the Lops were poor with the exception of the first, a Blue-and-white doe. Himalayans fair, the first a good one. In Silver-Greys, which was the best class, those noticed were a mere toss-up for position, as all were good. In the Variety class first was an Angora, second Grey Dutch, and third a Belgian Hare; but the best was a Silver Cream unnoticed, and the Belgian Hare should have been placed second, with the Angora third.

JUDGES.—Mr. J. Dixon, Clayton; Mr. W. F. Entwistle, Wyke.

HUNTINGDON POULTRY SHOW.

THE Huntingdonshire Agricultural Society held their Show on the 18th inst., in Lord Sandwich's beautiful park close to Huntingdon.

The poultry Show was certainly above the average of shows at this time of year. Its chief feature was the *Dorkings*. There were four well-filled classes of this old English breed, the adults being in wonderful plumage for July. About some breeds there seems an ever-changing fashion of popularity, but *Dorkings* always hold their own, and several breeders, famous in other varieties, have lately told us that they were inclined to abandon them for *Dorkings*, disgusted with the trickery by which they were frequently beaten. The one-guinea prize for the best pen in the Show deservedly went to Mr. Parlett's grand pair of adult Dark *Dorkings*, birds of the true *Dorking* type and good all round. How the best pen in the Show could be other than the best *Dorkings* we could not understand, for this pair did not receive the *Dorking* cup. Mr. Peel's pen, second in this class, contained a magnificent hen. The first pair of *Dorking* chickens were not very large, but very white in feet. In the second pen was an immense pullet with sooty feet. The *Dorking* cup went to Mr. Peel's Dark cock first in this class, a broad bird but almost without tail; second was a Silver-Grey very pure in

colour, the Bath cup bird. The class for pairs of hens was a good one; the winners were nearly equal, but we thought rightly placed. The *Brahma* classes contained some individually good birds, but were as a whole poor. In the class for Dark cock and hen Mr. Lingwood was placed first, the cock being a grand bird of its owner's particular type; the hen combined good size with capital pencilling. The hen, too, in the second-prize pen was beautifully marked. Only one pair of *Lights* appeared, chickens, very forward and excellent in colour. Two single cocks were shown, first an immense Dark bird very silvery in hackle and saddle for the time of year; second a somewhat yellow *Light* bird. *Cochins* were fair, but not numerous. The cup went to the first pair of *Buffs*, the cock a good *Lemon Buff* bird, the hen well shaped but not large. The second pen contained a very Dark cock and a large hen not well feathered. In the other *Cochin* class poor *Whites* were first, grand-looking *Partridges* second. These birds were pulled down by some abnormal swelling of feet. *Game* were generally in very poor condition and plumage, even the representatives of the famed *Stowmarket* yards not looking at all themselves. Mr. Deacon's first *Black Reds* looked well for the time of year. The cup *Brown Red* cock was in very poor plumage. As usual now in the *Hamburgh* classes the *Golden-pencilled* were the most numerous, and best by far as a class. The cock in the first-prize pen was rich in colour and capital in some points, but disfigured by some white in the face. The cock in the second pen had a suspicious-looking comb. Dr. Snell's pair of *Silver-pencils* well deserved their cup. *Game Bantams* were a poor lot. Mr. Winwood's pair were the only birds with any *Game* style. In the *Variety Bantam* class moderate *Golden Sebrights* were first, neat *Black Rose-combed* second. One poor pen of *Spanish* alone appeared. In the *Variety* class *Crève-Cœurs* first, and good *Golden Polands* second.

Ducks were good classes. We were very pleased to see that the *Judge* went in for condition and not abnormal obesity, which so unfortunately often now carries the day. The cup went to fine *Rouens*. In the *Variety Duck* class *Black East Indians* and *White Call Ducks* won. The highly commended pair of *Black Ducks* were beautiful in colour, but far too large for the prevailing taste in this breed. *Turkeys* had good classes, and *Geese* very good. The cup went to a grand pair of *White Embden*, which looked really useful stock birds and not stuffed for show. In the classes for *Goslings* the *Grey* were decidedly ahead of the *White*.

Pigeons had five classes. In *Carrier Duns* were first, the cock a grand bird; good *Blacks* second. The *Pigeon* cup went to Pouters, capital pair of *Whites*; *Whites* were also second. *Almonds* carried off both prizes for Tumblers. *Antwerps* had a large and well-filled class. In the *Any other variety* class *Red Barbs* took the first place, and *Lahores* second. The latter are a large breed with very distinctive markings.

Mr. Tegetmeier officiated as Judge, and his awards appeared to give general satisfaction.

BEDFORD SHOW OF POULTRY, &c.

THIS Exhibition, which took place on the 19th inst., was a capital little meeting. There were about 260 pens, and the quality was on the whole excellent. The prize money has already been paid, which certainly is very praiseworthy, and we understand the catalogue with the awards was sent to every exhibitor, which is an admirable plan, and will do the Show more good than the expenditure in doing it will create loss.

Dorkings came first in the catalogue, when nine pens of all colours did battle for the two prizes. The two prize pens were both good and deserved their places. Mr. Cresswell sent two capital pens, and Mr. Allen also a good pair. *Cochins* followed; a pretty pen of *Whites* were first in their class, while the second prize was awarded to a very good pair of chickens, well grown and most promising. In the next class, which contained five pens, a good pair of *Partridge* came in first. *Game* had four classes, but only made thirteen pens. Mr. Matthews, however, pulled off the £5 5s. cup for the best pen in the Show with a smart pair of *Duckwings*. Many birds, however, appeared the worse for the wear and tear of the season; and in *Brown Reds* only one pen, which were of fair quality, appeared. *Spanish* made a good little lot of half a dozen pens; an extra second was awarded in this class. In the *Pencilled Hamburghs* a very pretty pen of *Gold*s were first; Messrs. Cresswell and Long also had good pens of the same colour. *Spangled Hamburghs* mustered thirteen pens, in which the quantity was superior to the quality. A mixed class of *Brahmas* came next, where Mr. Lingwood maintained his reputation by coming in a good first; second going to a pen of *Lights*, well shown. The *Variety* class numbered nine pens, where the quality was excellent, and the *Judge* awarded two extra third prizes. The first went to truly beautiful *Black Polands*; the hen a great beauty and the cock admirable in all points. Good *Crèves* came in second. *Black-breasted Game Bantams* only brought four pens, and the next class but two, one of which was placed out of competition

machines for making comb foundation are too costly for me, or I should very much like to have three or four intermediate between worker and drone size, and so aspire to eventually breed my worker bees as large as present drones. What a wonderful lot of flowers might then be brought under contribution to fill our supers! I commend the idea to those bee-keepers who have leisure and money to carry it out.—JOHN HUNTER, *Eaton Rise, Ealing.*

FEEDING SWARMS AND COMB-BUILDING.

As the present season has been unfavourable for bees in many parts of England, late swarms are not in a good condition for winter. No one can say what the weather may do for bees in August if they be taken to the moors. Strong hives have been known to gather from 50 lbs. to 60 lbs. each on the heather; in some few cases more than 60 lbs. in very fine seasons. But as a great number of English bee-keepers do not remove their hives to the heather, I deem it well to suggest that prompt and proper attention be given to the feeding of late swarms which are intended to be kept for stocks.

Idleness in a bee hive during the summer months is the mother of mischief. While bees have a disposition to build combs and multiply population it is a stroke of good policy to keep them pretty fully employed at this work. This can be done by artificial feeding in unfavourable weather. A few pounds of sugar made into syrup will be of far greater service to swarms now than it would be at a later period of the year, for every square inch of comb built now will yield a hundred bees (two sets of brood) by September. It is of very great importance to have swarm hives well filled with combs and brood now if strong stocks are wanted for another year. Later in the season bees are less inclined to build combs and multiply numbers. Artificial feeding then is more likely to cause the bees to elongate their cells, and thus thicken their combs for store room for winter food. If artificial treatment be necessary to prepare stocks for winter, the sooner it is resorted to the better for the reasons now given.

Late feeding is less productive of comb and brood, and is attended with greater risk. There is the risk of cold inclement weather destroying bees in fetching water for their young, and also of chilling the brood in the combs. By feeding swarms now they may be converted into valuable stock hives. Syrup well administered will cause the bees to recommence comb-building, and as comb-building progresses so will the population of hives. Six or eight combs well filled with brood in August will fill a hive full of young bees by the end of the month, making it a strong and eligible stock for another season. A young and energetic farmer said to me the other day that "manure is the honestest thing in the world; that money is honest, but manure is honest because it yields a larger return." I turn from this clever and successful farmer to the bee-keepers of England, to remind them that sugar properly given to bees is a good investment, and will in time yield a large return. Generous feeding in seasons of scarcity not only prevents disappointment and loss, but puts beginners on the high road to success.—A. PETTIGREW.

BEE-KEEPING.

LAST September I drove twenty-four hives and made them into twelve, and fed them to the weight of 25 lbs. to 35 lbs. This spring I drove six swarms; the other six I put bell-glasses on 9 inches across. One glass I have taken off with 10½ lbs. of honey in; three more I have are not quite sealed-up. The other two have partly filled their glass, and have left it by swarming; and ten or twelve stocks I fed, six I drove, and two swarmed, making twenty in all. Six I drove twenty-one days after swarming, the others I have left with glasses on; but I am very pleased to state that I found no young bees in any of my hives but one, and not many in that. Now, I should like to drive my twenty stocks the latter end of this month and feed them up, and then in September I shall be able to get some off of my neighbours. This year I mean driving one hundred stocks and feeding them up to fifty, for I can get plenty of bees by paying 1s. per hive. The worst job I have to do is to get the bees out of the glass.—W. H. ATTWOOD.

A SNAIL CONFINED IN WAX.—In a chapter on the ingenuity of bees I stated that I was not sure whether I had seen in my early days a dead snail confined in wax in one of my father's hives. About a fortnight ago I found a dead snail in one of my own hives, not confined but covered with wax. It was daubed over with wax and slightly sealed to the board on which it lay. I look on this fact as a confirmation of what some have said in illustration of the wonderful sagacity and ingenuity of bees.—A. PETTIGREW.

OUR LETTER BOX.

DRIVING BEES (J. H., Sussex).—If your object is to get a large harvest of honey this year you cannot do better than drive the bees from the old hive

and unite them to the second swarm, and feed them into a stock strong enough for winter, and drive the bees from the first swarm hive into the straw below it. This can be easily done, and you need not trouble yourself to find the queens. When the bees of the old hive are united to the second swarm one of the queens will be destroyed; it does not matter which, for both of them are young. The best time to unite the swarms will be about the end of August, when most of the brood of the hives will then be hatched. Your attention to feeding during the spring months has been followed by comparative success in the present season.

TREATMENT OF DRIVEN STOCK (S. W. Fenn).—You say that on the 14th of July you drove a swarm of May 25th which you found three parts full of brood, and you ask if you were to let it stand without any bees (old ones), whether "the young would come off all right and do good." They may perhaps do well enough, but it is a risky thing to do. It would have been much better had you put this hive, empty of old bees but full of young brood, in the place of some other strong hive in the middle of a fine day, shifting the strong hive to another stand some distance off. We would advise you not to drive your other swarm so late in the year, and in such a bad season too. If you have resolved to do it for some reason not stated you had better wait till the second week in August, and then feed both hives liberally; but do not treat the brood as you did before, if there should happen to be any, or you will certainly lose the hive. In such cases it is often a long time before the young bees find out their want of a queen, and when they set about repairing their loss there is often no suitable brood to work with. Not only so, much of the young brood perishes for want of attention from the nursing bees that have been removed, and the whole hive suffers from corrupting brood dead in the cells. Certainly no worse way of treating your bees could you have adopted.—B. & W.

REMARKS.

18th.—Windy and rather cold, but very bright all the forenoon; rather less so afterwards, but fine all day.
19th.—Fine but rather dull at 9 A.M.; slight shower at noon and again in the evening; a dull and almost sunless day.
20th.—Very fine morning, rather dull about 2 P.M., but as a whole a very fine day, and a starlit night.
21st.—Fine morning and a most beautiful day throughout.
22nd.—Rather grey and dull till noon; fine afternoon and evening, though looking stormlike at 8 P.M.; fine after.
23rd.—Dull morning, showery day, and wet night.
24th.—Not very bright early, but very fine after, and splendid evening.
The temperature of the week very like that of its predecessor, but weather beautifully dry and pleasant generally, only one really wet day.—G. J. SYMONS.

COVENT GARDEN MARKET.—JULY 25.

A VERY heavy supply of goods this week, and all making fair prices. The late rain has completely damaged the Cherry crop, samples from all parts of the country arriving in very bad condition. Strawberries are nearly over Currants plentiful; a good crop, especially Black.

From observations taken near London during forty-three years, the average day temperature of the week is 74.5°; and its night temperature 50.6°.

REMINISCENCES OF ROSE SHOWS.

THE 23rd of July and a wet day. Roses out of doors existing and that is all—not blooming, nor yet, so far as I can see, growing; but alive and, let us hope, kicking under the ground. All the Rose shows over for the year; the great nurserymen hard at work budding; here and there a bloom of a Tea Rose to be seen struggling against the fog and rain.

Such is the state of things as I sit down to write on Roses. Not an inspiring scene, nor a bright and glorious prospect, nor exactly the kind of thing to inspire one to write glowingly and enthusiastically of our pets; but in spite of all I must try to give you a few reminiscences of the days that are gone—days spent happily in tented field and shire hall, or in noble palace of crystal; and if I fail to interest or please any of your readers, if never a smile illumines the face as they read my ravings, well, let them remember that I am but a Wyld Savage, and perhaps am “hipped” just now. If the wine proves to be corked or the olives bad, at least forgive me, for I have written very many accounts of shows and cannot always “fool it well.”

To begin with the year that is just over. Pardon, I mean of course the Rose season; but I get so in the way of looking upon everything in connection with Roses that to me 1877 is over. Looking back, then, over the last season and taking stock of the various shows and exhibitions, I once more have to record Mr. George Paul as the champion exhibitor of the year. Taking seventy-two distinct varieties as the head or champion class, and counting only the great metropolitan exhibitions, it will be found that Mr. Paul won the first prize at the Alexandra and at the National. He was beaten at the Crystal Palace, it is true, but that show was held at so early a date that hardly anyone was in, and Mr. May of Bedale, Yorkshire, who won, cut his blooms entirely from under glass. However, as Mr. George Paul neatly puts it, “We were beaten there, yes; but we went down to Leeds, just to show our friend that we were still alive, and there we turned the tables.” The chorus of disapprobation with which the schedule of the Crystal Palace was received was, and I hope will be found to be so to the Directors, a caution. Already a round robin is being prepared, stating that if another such schedule is sent out none of the leading exhibitors will show; and it is to be hoped that next year the Manager will retrace his steps and once more make his show what it used to be—the leading show of the season. This year there can be no question it was the worst.

Among amateurs Mr. Baker is still *facile princeps*. He was beaten, it is true, at the National for the head class, but he was first at the Alexandra in all the amateur classes in which he could compete, and at Hereford he took the first prize in the four leading classes, and at the National he was first for thirty-six, twelve trebles, and in a multitude of other classes.

No. 853.—VOL. XXXIII., NEW SERIES.

But Mr. Jowitt, besides winning the challenge cup and the prize of the year, has shown splendidly all the season through, and we must indeed take care in the west lest our champion is reduced to accept second honours next year. From the first show up to the very end of the season Mr. Jowitt was in splendid form. He was first at Sydenham on the 23rd of June, and he was first at the Aquarium for twenty-four (the leading class) on the 18th of July, and during the interval he showed sometimes at two shows a-day. He is a splendid grower.

Of all the curious places for staging Roses commend me to the Royal Aquarium, Westminster. I have set up my blooms at Clifton next to a wolf, who seemed to eye the proceedings with the greatest contempt. I have had parties asking me, “What’s o’clock?” till I was weary of answering; but all these companions were as nothing to those I met with at Westminster. “Just wire this Rose, will you?” I am saying to my man, when bang thump comes down a little girl from the very top of the dome into a net. “Well done! well done! but kick out your left leg a little more,” is the astonishing remark made by a great swell on the stage. We look up in amazement to see a younger member of the Zazel family mounting up to the top of the roof to repeat the feat, as if it were only crossing a room. “Bah!” said a great rosarian with a sign of disgust, looking at his Roses; “are we taking part in the pantomime of Beauty and the Beast?” “By no means,” said another great exhibitor, as he gently touches up a bloom; “this is Paradise and the Feri.” Then presently as we are judging, the infant Zazel dressed in her tights comes skipping with a rope all among the boxes, raising a most penetrating cloud of dust which settles on all Mr. Cranston’s best blooms. Then towards the close of the second day, when we went to remove our boxes and blooms (?), we found what I may best describe as *box et praterea nihil*, for every bloom had been—well, borrowed let us say. “Well,” said my man, as he found a stranger collecting a few Rose leaves, the gleanings of the harvest, “you are driven short.”

How amusing also is it at some exhibitions to hear amateurs extolling some novelty (?) which they believe that they and a few particular friends alone possess, and when we rush to look at it, find that if not as old as the hills it is not much younger than the United States. This year at Torquay, in the midst of all the bustle of staging, “Sir,” said an excited exhibitor to Mr. Curtis of Torquay, “let me show you a bloom better than all your Roses put together; one you have not got, I know. Here you are. There, what do you think of that?” “Monsieur Etienne Levet.” Then, on the other hand, how often do we meet with exhibitors who are far from pleased with what they see, and who lash themselves with fury without the slightest reason, as it seems to us. I remember at Bath when the Royal Horticultural Society held their provincial Show an exhibitor rushing all round the tent detailing in a loud voice his grievance. “Whatever is the matter?” I asked of Mr. George Paul. “The gentleman appears to be in distress about a waterpot,” was the

No. 1505.—VOL. LVIII., OLD SERIES.

reply. For all the to-do arose from someone having borrowed that necessary article for a few minutes.

And as judges, what various kind of treatment do we meet with from exhibitors and the public generally! The leading nurserymen look round when the judging of their exhibits is over. "A rather close thing between us and Cant; but I think you are right," remarks the champion on one occasion. "Nothing to find fault with to-day," says another giant. But go to some provincial show where some third-rate nurseryman stages a seventy-two and meets Mr. Cranston or Mr. Turner, and hear his remarks on the judging. I remember once at a show in Staffordshire being so abused that I felt very happy that I was not personally maltreated. "You call yourself a judge!" said a man from Nottingham, "and place me third! Why, when I uncovered my boxes this morning all the amateurs said I was first, and then I came in to the show and find you have placed me third. Why, a ghost of an amateur could see who was first if he rode round the room. Hole I know, and Pochin I know; but who — are you?"

Contrast this with the calmness of others who are content to take the second, or even the third or fourth place, or even to be left out in the cold altogether, when they know they have not disgraced themselves. I remember one year staging in every class at the Crystal Palace, and taking not a single prize. When my old man came home next day with the boxes I greeted him with, "Well, we have done nothing this time." "No, sir," said he quite cheerily; "no, and no one down our way has. D—— got ne'er a prize, and C—— did not either, not even for decorations."

It is not often that an amateur beats a nurseryman in the large classes. Sometimes in Teas or in twelve of a sort this happens; but very rarely in the forty-eight or seventy-two. Yet I remember Mr. Baker beating Mr. Keynes and others at Exeter for forty-eight, and now the Rev. Canon Hole has secured the greatest of victories over Mr. Cranston and two other nurserymen. I wish I had seen that fight, it must have been a grand one; but the Secretary of the Nottingham Show did not send me a schedule till the Show was over, and so I knew nothing of it. [Neither did he send us a schedule.—Eds.] As Mr. Cranston, from the way he showed at the Aquarium the day before, must have been in splendid bloom, this feat of Canon Hole's is a very great one, and I do not suppose that amid all the triumphs of his life there is any that he will value more highly, and much do I congratulate him on his great success. We in the west and south are so much earlier than our friends in the midland counties that we rarely meet at the shows. Even the 4th of July, the day the National show was held, was too early for Canon Hole, so that it was no small success on his part to obtain third honours there. Next year if a show is held in the north or midland counties I expect he will have it all his own way.

And now the Rose show season is over, and as I look back upon it I cannot but remember with gratitude how much brighter it has turned out than at one time appeared likely. At the preliminary meeting of the National Rose Society the Secretary gave a most gloomy account of show prospects. He told us that neither the Aquarium nor the Alexandra would have a show, and the Crystal Palace would reduce their prizes; but each Show was held, and the only one that appears to have succumbed is that of Birmingham. If next year the Royal Horticultural Society have a Rose show of their own, besides having one at their provincial meeting, and the National hold not only a London show but a country one as well; if Birmingham decides to give the public one more chance of supporting Rose shows, then next year we shall indeed have a feast which will even satisfy a—WYLD SATAGE.

STRAWBERRY CULTURE.

A SHORT time ago Mr. Douglas suggested that there were possibly some cultivators who doubted the soundness of the advice that has been given when it has been recommended to plant Strawberries annually. The advice may be and is perfectly right, but those who follow it must do so exactly, or failure will most likely result. Not, be it noted, because the advice has been wrong, but because it has not been fully and precisely carried out. When Strawberries are planted annually and good crops are produced the first year after the runners are planted it is of vital importance that good runners are obtained and planted early in good soil, and then, if proper cultural care is given to them, they will form crowns and produce crops as certainly as will plants which are grown in pots

and forced. It will not do to defer the planting of runners until September or October, and then plant them of the same small size as they were in July; such runners will not produce a good crop until the second year. If well-prepared ground is not ready early in August, and very strong and well-rooted runners are not also ready for planting at the same time, it is as well to plant later runners in nursery beds, removing them to their fruiting quarters as soon as they show signs of growth in the spring. Such plants will have a whole season of growth before them, and ought to produce a splendid crop the year following. But the more economical plan, and especially where the soil is rather light and the plants take hold of it quickly and grow freely, is to plant strong well-prepared runners in their fruiting quarters as early in August as possible. If they can be planted in July all the better, but they cannot always be obtained then, and especially during a rather late season like the present.

I have for some years had two gardens "under my eye;" the soil of one garden very light, the soil of the other very strong. Strawberries are grown in both of them, and most people who see them consider that they are grown well. Several years of experience have proved that the mode of procedure best for one garden is not the best for the other, which plainly proves that no one rule is applicable to all cases, and herein is the sequel of the doubts that Mr. Douglas referred to that his practice was not reliable. It is perfectly reliable if carried out properly and the conditions are favourable—that is, if really strong plants are really planted early, and the ground is sufficiently free for their speedy establishment and quick progress to maturity.

In my "light soil" garden the runners arrive at maturity the first season, and yield splendid crops within a year of being severed from the parent plants. They are planted if possible on ground from which the early Potatoes have been dug. If the runners have been layered in pots they are planted as recommended by Mr. Douglas in rows 2 feet apart, or rather more, and 18 inches between the plants; but if they have not been prepared in pots they are planted "a foot apart all ways." I have never been able to determine which plan produced the best crops, but by both modes they are as good as I can desire them. When the latter plan is adopted (and both plans are carried out every year) every alternate row is chopped up immediately after the first crop has been gathered, and the remaining rows remain one year longer and no more. When I say the alternate rows are removed immediately after the fruit has been gathered I mean what I say; that term as I employ it does not extend over a period of two or three months. The mode of preparing the plants in pots is perhaps the more certain, and a less number of runners are required, but the other plan is often the more convenient. It is satisfactory to know that both modes answer the purpose intended, and I adopt them simply because I have a fancy in every possible operation for having "two strings to my bow," and as a consequence I have found that I have sometimes "hit" with a given crop when my neighbours have "missed." A good general always preserves a line of retreat, and has his van well supported by reserves.

Previous to planting the soil is liberally manured and deeply dug. In addition to the manure fully 2 oza. of common salt are spread over each square yard, and the ground, being light, is made firm before planting. The plants are afterwards watered as required, and the surface of the bed is mulched with short manure, or, failing that, lawn mowings. The salt in the soil and the mulching on it are of much service in retaining the moisture. The first crop is nearly always better than the second; a third crop in such soil cannot be relied on.

In the other, the "heavy soil" garden, a different mode of culture is necessary. The plants in this garden, if planted in August, do not become established sufficiently quickly and make sufficient progress to produce anything like a full crop the following year; but when they are established they bear prodigiously and continue bearing satisfactorily for at the least three years, and if the crowns are thinned out good crops are produced by the same plants for five or six years. In this heavy-soil garden it is found advisable to prepare the plants by planting them in nursery beds early in September, placing them in their fruiting quarters as soon as growth commences in the spring. There is then no necessity for hurrying the ground into condition—indeed, heavy soil cannot be profitably hurried for any crop, but it is well prepared by being roughly dug and thrown into ridges, these ridges being broken as often as is convenient when they are crusted with frost.

The soil then becomes friable and, as it is locally termed, "mouldy" by the planting time arrives, and the plants become established the more quickly on account of the care that has been exercised in preparing the soil. In this strong and also good soil, where the plants continue fruitful for at least three years, it is found necessary to have the rows of Strawberries much wider apart than in the light-soil garden, where the plants are only allowed to remain two years at the longest. Where they grow luxuriantly—when they do start—and continue for three, four, or more years, I have found the best results by having the rows 3 feet apart. There is no waste of ground by that wide system of planting, for a fine crop of Lettuces is grown between the Strawberries the first year, and an equally good crop of winter Onions the second. After these—indeed before—the Strawberry crop is always worthy of the ground which the plants occupy, and if sold would give a better return than I think any other crop occupying the same area of ground in the garden.

Thus the mode of culture that is adopted by a given crop must be determined by circumstances. The plan of growing Strawberries in light soil—namely, planting early and rather closely and taking only one, or at the most two, crops is only suitable for that soil, and if it is tried on soil of a strong heavy nature disappointment will probably result. On the other hand, planting thinly in a light and dry soil and permitting the plants to occupy the same ground for several years is not the most profitable mode of culture in such a soil. In many gardens—and the plan is especially applicable to the small enclosures of amateurs—valuable crops of Strawberries may be produced by planting marginal lines of them by the sides of walks or borders. Such lines have a neat appearance, and usually yield fine crops of fruit. The plants when grown in that way in single rows need not be more than a foot apart, and they should be planted now.

As to sorts I find President the most profitable for light, and Sir Joseph Paxton for heavy soil. Vicomtesse Héricart de Thury is a good early variety for any soil. Dr. Hogg and British Queen are not yet surpassed for high quality, and Elton and Eleanor are the best late sorts.—W. S. P.

PACKING.—No. 2.

FLOWER BOXES are 24 inches by 16 outside, and 8 inches deep inside, for packing Roses and other flowers which will not bear much pressure. Stands are made to fit in the boxes in the following way:—A half-inch board about an eighth of an inch less in length and breadth than the inside of the box, and pierced at regular distances with twenty-four holes, is fixed to four legs 8 inches long in such a way that when placed in the box it will stand firmly about midway between the bottom and the lid, and the lid when nailed down will just touch the tops of the legs and hold all securely in its place. Roses must be selected according to the weather and the interval between gathering and using, but generally speaking they may be about half blown, and they must be cut while the dew is on them, either late in the evening or before five o'clock in the morning. It is better to cut them even three days before they are required for use, if done at the proper time of day and kept in a cool place, than to cut them in the hot sun for immediate use.

A boy carries one of the above stands to the plants, and a qualified lad or man selects the Roses and places two or three blooms in each hole, keeping half an inch clear all round the sides so that when placed in the box they cannot possibly rub against it. When filled the stand containing four to six dozen blooms is taken to the packing shed, examined, and any faulty blooms removed to be replaced with others more perfect. It is now turned-up edgewise on the bench with the stems of the flowers pointing to the operator, who takes hold of each bunch with his left hand, pulls it in close to the board, and with the right hand inserts a wedge of elder or other soft wood so firmly that the flowers cannot possibly shift till the wedge is withdrawn.

When all are firmly wedged in the stand is placed on the bench with the stalks of the flowers uppermost, and when examined underneath a clear space of half an inch at least must be seen between every flower and the bench. When it is seen that it is impossible for any flower to touch either the sides or the bottom of the box, the stand, which will fit any one of a number of boxes for this purpose, is placed in position with the flowers upside down. If it can move about at all in the box a wedge or two will make all safe. Any stalks which will

be likely to touch the lid are now shortened, and the space which is now about two-fifths of the box is filled carefully with long loose flowers, the stalks of the Roses sticking-up between them and preventing them rubbing and crushing. A piece of soft paper is placed over all, and the lid is nailed down and completed. We send seven to ten of such boxes as I have described at a time, and some of the spaces between the Rose stems are filled with moss or salading according to what is required.

Now, I suppose I shall be expected to say what kinds of Roses I find the best suited to my purpose. But although I pack in such large quantities, my experience with different kinds is rather limited, and necessarily so, it being expected that I should send one colour only at a time, and if possible only one kind. Well, then, how many plants do your readers suppose it would take of Charles Lefebvre or Capitaine Christy to furnish five hundred half-expanded blooms on a certain day? I should be afraid to guess, but I think I should have little room left for growing Cabbages. No, H.P.'s are not the Roses to cut in quantity. You may have, if your plants are large, 3 or 4 feet through, and on their own roots as mine are, on an average, perhaps, three blooms from six plants, but if you want quantity as well as fair quality you must go to the Bourbons and Teas.

Paul Verdier never has an imperfect flower, and is a model of a Rose for exhibition or any other purpose. It is nothing uncommon to cut a dozen perfect blooms at a time from one medium-sized plant, and its scent is delicious. It is rather late in flowering, and consequently all the more valuable to me. Coupe d'Hébé lacks a little in substance, but in colour and shape it is not yet beaten, while for quantity of good blooms it beats everything I have seen excepting the one named above. Its shape is formal without being stiff; some of the much-belauded newer Roses look too much as if they had been clipped into shape. Paul Ricant is not quite bright enough, but I was glad to use it extensively before I raised a stock of Paul Verdier.

Gloire de Dijon, of course, is the first and last of the season, and every bit of wall where nothing else will grow a Gloire de Dijon should be planted. It is, however, best on its own roots in a northern aspect, and I have nearly made up my mind that this is the only way to grow Tea Roses properly. They neither like much frost, much sun, nor much coddling-up. But I must leave the results of my experiments with this most beautiful class till another time, and since I have run away from my subject of packing, I must also leave the other items for a future paper.—WILLIAM TAYLOR.

WHOLE VERSUS CUT POTATOES FOR PLANTING. DISEASE.

You are quite right, Messrs. Editors; I did not advise the cutting of kidney Potatoes for the simple reason that I never cut them because they have not sufficiently numerous bold eyes, and I never recommend any practice that I do not adopt. I do not for a moment dispute the excellence of the crops of "A KITCHEN GARDENER" from such seed tubers as he has planted, for the sufficient reason that I have had many good crops from tubers of the same nature. The usefulness of such sets is admitted, but the prejudice against cut sets is not quite eradicated. On this point I think "A KITCHEN GARDENER" is not quite competent to speak with authority; at any rate his experience of this season alone does not enable him to do so, for he says, "every one of the tubers were planted whole." He has thus really had no means of comparison, and yet he decides in favour of whole tubers. Let him next year fairly try cut sets of large Potatoes, each set having at the least two bold eyes, and he will find such growth stronger than that from small seed tubers planted whole, and I strongly suspect that he will find the produce of greater value also.

But I do not regard the sets employed by "A KITCHEN GARDENER" as being small in the sense that I had in view; but I desired to denounce the tons of trash which are annually sold in the markets as seed, which seed is bought and planted, and trashy crops follow. It is by that bad practice in conjunction with another common practice which is equally reprehensible, of allowing the tubers to remain to grow into matted heaps before being planted, when the sprouts have to be rubbed off: such treatment impaired the constitution of the Potato, and rendered it additionally liable to disease. I do not suggest that "A KITCHEN GARDENER" adopts such a system; he

knows much better than to do so, or to plant trashy seed either, but there are hundreds who act thus unreasonably, and injure the value and jeopardise the condition of the prince of English root crops. It is because I have seen so much that is erroneous in principle adopted in the treatment, the abusive treatment, of seed Potatoes, that I have, and shall, and will, employ my voice and pen against it until I find a more rational plan established, and I ask with some confidence "A KITCHEN GARDENER'S" assistance in abolishing a custom which I believe he equally with myself regards as pernicious. I will not further dwell on the matter now, but will allude to what is at the present more important and reasonable—the avoidance of disease.

If dull, moist, and warm weather prevails an outbreak of the murrain is inevitable; indeed, it is on record that it has made its unwelcome appearance in more than one place. When the disease is once established nothing will destroy it, unless it is the new agent *salus*. Considering the source of this remedy, I think it ought to be tried by as many as have the means of doing so, and records of its efficacy or otherwise, especially not forgetting the "otherwise," be published.

My plan of preserving the crop is an old and simple one. I cannot conquer the disease, but I can avoid it. The plan is that which was suggested in your columns last week, a plan which I remember has been steadily recommended ever since I commenced reading your pages. It is the planting of early-ripening sorts, and digging the crops before they are attacked by the disease. Whenever I have done my duty in this respect I can truthfully say that I have never had a failure, and the disease, so far as regards my garden crops, has years ago lost its terrors.

As soon as the tubers have attained about their full size they are taken up, if fungus weather—that is, if several dull moist days threaten, whether the haulm has decayed or the tubers are ripe or not. It is a singular fact that they will ripen nearly as well out of the ground as in it; and if at the time of being taken up they are close and sad when cooked, and do not apparently contain a particle of starch, they will eventually become "mealy," and contain starch in abundance.

Whence it comes and how it comes is a question I am unable to answer—a question which is, perhaps, worth the notice of some of your scientific readers and correspondents. Potatoes when taken up thus early should be stored thinly, but not dried in the sun. The place, indeed, cannot be too shady provided it is tolerably dry.

But all cultivators cannot find time for digging their crops and storing their produce thinly just at a critical time. In that case, as you suggested last week, the haulm may be "pulled off, not cut." No doubt many growers will smile at this recommendation; they have tried this practice and failed to save their crop. But I think I have as good grounds to smile at their failure as they have at the advice given concerning it. When the practice fails it is the fault of the operators, who have erred in their judgment as to the time of removing the haulm, and by their tardy movements and indecisive action have suffered the enemy to steal a march on them, and which has thus rendered their efforts of no avail. The haulm must be removed before the disease strikes the crop. If the work of either taking up the tubers or removing the haulm is deferred one day too long all may be lost. If the haulm is removed in time—that is, before the disease appears, the tubers beneath the surface are perfectly safe, let the weather be what it may, and the murrain rage with all the virulence of which it is capable. At least I know that is the case in the district and in the soil where I have practised for several years, and I presume that the murrain has no geographical fancies.

With late varieties of Potatoes I have not always, indeed seldom in years of great disease, been able to save the crop. To dig such crops as Paterson's Victoria in the Potato-growing districts of Yorkshire and the north-west corner of Lincolnshire, where hundreds of acres of Potatoes are grown, before the disease is established, is to dig up the crops before the tubers have attained to a useable or marketable size, for such a variety as Paterson's Victoria, for instance, does not form tubers so quickly, or they do not attain to a sufficient size so speedily in those districts as they do in Sussex under Mr. Luckhurst's management. If they did I should do as he does—dig them up whether the haulm was green or not, or whether every tuber slipped its jackets during the process of removal. If they have attained to a good size that is sufficient; the question of ripening may be safely left to take care of itself,

provided—which is the real difficulty with many—that shelter is provided, or can be improvised, where the tubers can be dried gradually and stored thinly.

Sufficient evidence has been forthcoming that Mr. Luckhurst preserves his main as well as his early crops by digging them when the haulm is still green, and before the skin of the tubers is "set," but I am much afraid the plan is only applicable to the southern districts, where not half so many Potatoes are grown as in the north. If your able Sussex correspondent can tell us northerners how we can surmount our difficulties—namely, late swelling of the tubers and a lack of convenience for storing them thinly, he will deserve well of his country, inasmuch as he will be the means of saving from destruction not a few sacks merely but many tons of the country's food.—A NORTHERN GARDENER.

ROSES IN POTS.—No. 2.

SMALL plants for decorative purposes, such as have been frequently seen and admired at many exhibitions during the present season, ought, I submit, to be much more commonly seen than they are in private gardens. These small but useful plants are obtained in the following way:—As early as they can be lifted in the autumn from the open ground they are potted in 6 or 8-inch pots, shortening the strong coarse roots if any, so that the plant can be placed in the centre of the pot. The tops are also shortened a trifle at the same time. The pots are then placed close together on a bed in the open ground, when some cocoa-nut fibre is thrown around and between them, and slightly covering the surface of the soil in the pots. This prevents the frost from entering the soil, breaking the pots, and injuring the roots. The plants remain thus plunged the whole of the winter. The rains falling during the autumn are generally sufficient to excite root-action, but should the weather prove very dry sprinkling overhead becomes necessary, but nature generally provides all the water required until the following spring. At the usual pruning time of outdoor Roses, which is as a rule the first two weeks of March, the potted plants are cut hard back to two or three outward eyes, and placed in a sheltered nook to break and perfect their growths and bloom. The blooms on these plants are not as a rule so fine as those produced by longer-established plants, but are very effective. This is a very simple way of procuring plants, but much time will be saved if established plants are purchased.

Plants established in pots over twelve months can be readily purchased; and, compared with the cost of most plants, Roses in pots are very cheap indeed. Having given your order for the quantity chosen it may be well to leave varieties to the sellers, as they are men of great experience, and would send only good sorts that would succeed well in pots. After receiving them they should be repotted. The largest and the strongest plants will require larger pots, and smaller or weakly plants may be returned to the same sized pots.

Roses, especially Hybrid Perpetuals, are fonder of strong yellow loam than almost any other plant. Teas should have a trifle lighter soil, and if the plants are received early in the summer plunge the pots up to the rims in short manure, and if a little manure is placed over the top of the soil so much the better. The plants will root freely, and by the autumn they should be as thickly rooted as good Strawberries in pots. According to the summer's growth depends the success of next spring's bloom. They must be watered as required during dry weather, and by the autumn they ought to have well-ripened wood. This will be found by the lower leaves turning brown and falling off, when they should be removed to some place of shelter from the heavy autumnal rains; if no place at hand turn each pot on its side. I place mine in cold pits and frames and give all air that is possible, only sheltering from heavy rains.—J. W. M.

THE AURICULA APHIS.

I REGRET to say, that notwithstanding all the care that I have taken—the using of entirely new compost, the potting of every plant myself, carefully washing any that seemed in the least degree affected—this pest has again appeared in my collection. As yet I have only examined one frame, and found three plants infested by it: oddly enough they were some of the healthiest plants in the frame. I enclose a portion of the root with one of the aphids on it. When found it was almost entirely enveloped in a woolly covering, but this has come off

I have of course isolated the plants, and shall forthwith examine the remainder of my collection. Happily they are not the best sorts; so as Mr. Worthington Smith says he believes his salus would finish them off I shall, instead of repotting now, try it, and if it does not cure them I can but repot later on. You can readily imagine what consternation this re-appearance has caused me. However, I have the advantage this year of knowing it in time, and to be forewarned is forearmed. —D., Deal.

CULTURE OF ZONAL PELARGONIUMS IN POTS.

At the summer show held at Wimbledon for three or four years past visitors have been particularly impressed with the well-grown examples of zonal Pelargoniums exhibited by Mr. Roser, gardener to A. Shaw, Esq., Park House, Wimbledon Park. A few days since I had the pleasure of seeing these at their own home, and a finer lot I have never seen before. None of that flat cart-wheel training, which is contrary to all laws of Nature, is practised, but medium-sized sturdy plants are grown in 6-inch pots with extraordinary and well-developed foliage, and fifteen to seventeen large and massive trusses of bloom, such trusses which it would be difficult to excel. The plants, Mr. Roser stated, were only struck last July. I counted the number of pips in a truss of a few varieties. The first truss contained sixty-six fully developed pips and thirty-six more to expand; a second had 103 expanded blooms with twenty-six more to perfect themselves; the variety was the Rev. A. Atkinson. The third truss was Mrs. Tate, a very pleasing pink, on which were 120 pips nearly all fully expanded. These heads of bloom were fully 6 inches in diameter at the bottom, and measuring from the bottom row on the one side to the same row on the other they measured just 10 inches over. They were truly superb, and as decorative plants grown in the ordinary bush-like form they are not to be surpassed by any summer occupants of our greenhouses. I was so pleased with them that I asked Mr. Roser to describe his practice for the readers of the Journal, and the following is the practice adopted by Mr. Roser as described by him.

About the middle of July, or as early after that period as possible, cuttings are taken off in the ordinary way and struck in the open ground, where they remain until they become well rooted, after which they are lifted carefully and potted in 60-sized pots, placing them in a cold frame or pit near the glass, drawing off the lights on all favourable opportunities, taking great care never to allow them to become saturated with water. About the middle of October they are placed on shelves near the glass in a larger structure, allowing them plenty of air on all favourable occasions, and between then and March only just water enough given to keep them alive. Early in March they are shifted into their flowering pots; the size employed the first year is 6 inches. After potting is completed they are again placed on the shelves until the second or third week in April, when they are plunged in ashes in a frame, the lights being drawn off during warm showers and other favourable times, and under this treatment the plants make rapid growth. All the flower buds are pinched off until the pots become full of roots—indeed, until within about six or seven weeks before the plants are wanted for exhibition purposes or for home decoration. At this time the trusses of bloom that are then throwing up are left, and now we arrive at the secret of success. In order to obtain these gorgeous as well as massive trusses the points of all growing shoots are taken off with a sharp penknife immediately above each truss of bloom, and the strength of the plant goes to swell the size of truss as well as the individual blooms. From this period the plants are fed with stimulants two or three times a-week, and with clean water as often as it is necessary to water them.

Zonal Pelargoniums, Mr. Roser says, should be grown from the time of inserting the cuttings until their blooming period in as light and airy a position as possible, in order that the wood may become very firm and matured, without which it is impossible to expect substantial trusses. After a fair trial with an extensive collection the following twenty-four varieties are found the most effective. The varieties raised by Mr. George, Putney, which have massive trusses, large pips, and the flowers on the truss remaining until the whole are fully developed, are Par Excellence (very large pipe), A. F. Barron, Terence, Enchantress, Lord Mayo, Mrs. J. George, Seraph, The Shah, Salamander, and Rose Unique; and those of Mr. Pearson's raising having the same qualities are Arthur Rogers, Corsair, Harrie Helen, F. R. Clifton, Col. Wright, Lady Sheffield, Mrs.

Turner, Mrs. Tate, Matilda, Rev. A. Atkinson, Chas. Burrows, and Col. Holden. Rose of Allandale, raised by Dr. Denny, and White Clipper, raised by Mr. Must, complete the number specified.

The plants continue in bloom for nearly two months. As the present is the time for inserting cuttings or procuring plants, a record of Mr. Roser's practice is seasonable.—AN EXHIBITOR.

AUTUMN CULTIVATION OF SALADS.

LETTUCE.—It is not always in the hottest days in summer that cool crisp Lettuces are most wanted. In very many places they are in greater demand from now until the new year than at any other time of the season. In spring, when every inch of ground in small gardens is rigidly utilised for the principal kinds of vegetables, the Lettuces are often planted in all sorts of unsuitable positions; but now, when many early Potatoes are lifted and other things cleared off from borders and such-like choice places, the Lettuce should have the best of these. Ground from which the Potatoes have been recently dug answers well for Lettuce. If plenty of manure was put in when the Potatoes were planted it will not be necessary to add more now, but the ground must be dug over and made fine and level on the surface.

We generally make it a point to sow Lettuce once a fortnight. This keeps up an excellent succession. Large or small patches may be sown according to demand. It is about ten weeks from the time the seed is sown until the plants are fit for use. Those sown about the beginning of August will come in by the end of September. From then onwards is when we want an immense quantity, and I fancy many others do the same. When the soil is very dry it is a great advantage to sow the seeds immediately the ground is turned over. The surface is moist then and in much better condition for germinating the seed quickly than when the surface is dried up. Do not sow the seed in close patches in beds and then transplant, but place it at once where the plants have to grow. Draw the drills 12 inches to 15 inches apart and 1½ inch deep. Drop the seed into these drills in patches from five to eight seeds in each. The Cabbage varieties may be sown 8 inches apart and the Cos 10 inches or 12 inches. It takes less seed to sow them in that way than sowing the whole length of the drill, and as five or six plants come up in each patch there is plenty for thinning-out and transplanting.

Sow three times in August, and the same number of times in September. The plants from the last sowing may not grow quickly, but they will become of use in the spring. The August sowings are the most useful in autumn. As soon as the first are large enough to transplant this should be done, as they will come in a few days later than those left to form the crop. The best situation for Lettuces in autumn is the most sheltered from frost and the most exposed to the sun. Frequent surface hoeings never fail to keep down weeds and impart vigour to the plants.

In wet autumns I have sometimes found it necessary to lift many of the Lettuces in October when they were nearly fully grown and plant them in frames as close as they would stand, and cover them over with sashes in unfavourable times. I have also potted some of them before placing them in frames, but this plan will not pay for the labour and space. The best Cabbage variety for standing the winter is the Hardy Hammer-smith. Amongst the Cos varieties I have a strong preference for the Black-seeded Bath.

ENDIVE.—The cultivation of this does not differ materially from that of the Lettuce. It is mostly grown for autumn use. The principal crop of it should be in by the first or second week in August. We sow both our Lettuce and Endive together on the same border and in exactly the same manner. They come up about the same time, but the Endive is a little later than the Lettuce in becoming ready. It bears transplanting well and snails do not seem to relish it. On rich soil the plants often spread out to a considerable extent, and a distance of 12 inches to 15 inches is not too far to grow them apart. In hot weather the Endive is far more liable to "bolt" than Lettuce, consequently a thorough watering now and again is never labour lost. Those coming to maturity in August and September may be tied-up to blanch the centre; but when there is much rain and snow they soon rot if tied-up, and then the best way to blanch them is either to lay thin pieces of deal over them or lift the plants and lay them in by the roots in a dark Mushroom house. I only recommend two sorts, White Batavian and Green Curled.

RADISHES.—These are always in as great a demand as Lettuces. Their cultivation is even more simple, at least they do not take up so much ground or labour. The soil for them must be open and rich. Those sown during August may still have a shaded position assigned them. After trying several ways of sowing the seed I adhere strictly now to making drills about 1 inch deep and 12 inches wide, and leave about 6 inches between each of these wide rows to step between for drawing the Radishes. In a narrow border where they can be reached from the walk this plan is unnecessary, and the seed may be sown broadcast. It should never be sown very thickly. The plants are close enough when they come up 1 inch apart. They do not all swell at one time. By pulling the largest out as they are ready the smaller are given more room. After opening the drills if the soil is dry water it well before sowing the seed. Those sown in September and October must either be placed in an exceptional sheltered position or in frames. The latter are much to be preferred. Melons and Cucumbers are often cleared out of frames then; often neither the frames nor the manure are wanted until the spring, and this is the very place to grow Radishes. Pull the old Melon or Cucumber plants up. Leave the soil; add a barrowload or two of leaf soil, of light dung, and mix it up with this old stuff. Give the whole a good watering, and then cover the seed lightly. Do not put on the sashes until it is necessary to do so. The longer and the more they can be kept off the better, as their being on when not actually needed only makes the plants tender. A frame sown early in November will give supplies until Christmas and the new year. Dry soil or poor soil causes Radishes to run to seed quickly at all times, and before doing this they are hot and poor in flavour. Turnip Radishes swell best in the short days; and then sow Red Turnip and China Rose.

MUSTARD AND CRESS.—These are simply grown. They may be sown in any corner of the garden, either in the sun or shade. In August and September we sow a few short rows every ten days on a little border in light rich soil. It is watered immediately it is sown, and in sunny weather a mat is laid over it for two days after sowing. In October and throughout the winter we never sow out of doors nor in a frame either. Half a dozen boxes 2 feet long and 1 foot wide and 3 inches deep are what we use. Two of these are filled at the beginning of every week. The seed is just spread on the surface of the soil, watered, and placed in a house with a temperature of 50°. The plants grow quickly there, and as soon as cut the box is emptied, filled with fresh soil, sown, and put back again. This is the cheapest way of growing Mustard and Cress in winter that I have tried.—A KITCHEN GARDENER.

ROSE MDLLE. MARIE FINGER.

I AGREE with Mr. Beachey that there is a distinct difference even in colour between Mdlle. Marie Finger and Mdlle. Eugénie Verdier. I have repeatedly seen them exhibited in the same stands when "distinct varieties" have been specified, and I have never known them to have been disqualified. As I could not speak of them except as growing in light soil, where there is a clear difference in colour, I wrote to a great grower of Roses on heavy soil, one who has grown as many prize Roses as probably any other rosarian, and his reply is as follows:—

"Mdlle. Marie Finger is two shades darker; the wood is also darker and has more spines than Mdlle. Eugénie Verdier, particularly at the base of the flower. They are distinct.

"With reference to Maurice Bernardin, Exposition de Brie, and Ferdinand de Lesseps, although somewhat alike they differ in their respective time of flowering. This year Exposition de Brie flowered first. Ferdinand de Lesseps is the brightest, and Maurice Bernardin is the darkest of the three. Though very valuable in a large collection they are not all required in a small one."

This will give "WYLD SAVAGE" a portion of the information at least that he requested from "A HEREFORDSHIRE INCUMBENT."
—A CIVILISED NATIVE.

ZINC LABELS.

"A TYRO, Co. Down," wishes to know if anyone has observed that the shoots on which zinc labels are tied die. I have for a number of years observed this effect, and the cause is that the shoot that has the zinc bound round it is 5° colder in frosty weather than the other part of the Rose tree; likewise in summer weather the shoot is from 5° to 7° hotter than the

other part of the Rose tree. In a Cucumber house provided with iron and zinc rods the Cucumbers died away wherever they touched rods of zinc or iron; so I had the zinc taken away and had some American deal sawed up in strips and nailed to the rafters, and the crop has never failed since.

Mr. Hinton is quite right in saying that Rose Abel Grand does well on its own roots. It has with me; and I will add that Maréchal Niel, Devoniensis, and Lamarque do better with them on their own roots than when budded on other stocks.—W. G., Gardener, Lynwood, Hants.

GALLOWAY ROSE SHOW.—JULY 17TH.

THERE is a class of teachers in the present day who run down anything like enthusiasm. Politics, religion, the affairs of everyday life, must all be regulated by the rule of thumb. Cold and deliberate reasoning is to enter into everything, and nothing of sentiment or poetry to be dreamt of. But what a dull world it would be without sentiment! How slowly we should move without enthusiasm! and how much does every successful undertaking owe to the enthusiastic rider of a hobby. Here in the far south-west of Scotland—in a country beautiful in its own style of beauty, but to all appearance the most unsuited for the Rose—is a flourishing Society, so flourishing that it attracts by its schedule some of our largest English growers, and so well supported that its balance-sheet shows no deficit; and I think everyone who exhibits or knows anything about it will say that not merely the starting of the Society, but its maintenance throughout, is due to the hearty enthusiasm of the Rev. G. B. W. Mackenzie of All Saints, Newton Stewart. And again, although under trying circumstances he has to record a success—the season, so backward and so unpropitious everywhere, has been especially so for Scotland—and it showed no little zeal and success in Rose culture that at the very time that the southern growers were meeting at the Aquarium, those in the far north could come together in friendly rivalry at Newton Stewart.

The Show was held, as last year, in the Victoria Hall, a very suitable room with one exception, that the roof lights threw the sun down too much on one table, a defect that might be remedied by tacking some light material over them. The tables were arranged lengthways and were well filled. The chief attraction was no doubt the two stands exhibited by Mr. Cant of Colchester and Mr. George Paul of Cheshunt, who took first and second prizes in the order named, the third prize going to Messrs. Dickson & Co. of Newtownards, Co. Down, Ireland; while in twelve Teas the order was reversed, Mr. Paul taking first and Mr. Cant second, Messrs. Dickson being still third. It will be needless to particularise the blooms in these stands, many of the old varieties, such as Général Jacqueminot, Charles Lefebvre, Comtesse d'Oxford, Duke of Edinburgh, Exposition de Brie, Mdle. Eugénie Verdier, John Hopper, Jules Margottin, La France, Marie Baumann, François Michelon, &c., being shown, together with some of the newer sorts—Marguerite de Brassac, an improved Charles Lefebvre; Madame Prosper Langier, Mdle. Marie Finger, Duke of Connaught (shown very fine by Messrs. Dickson), Prince Arthur (Mr. Cant's very fine seedling), Reynolds Hole, Jean Liabaud, very dark; Rev. J. B. M. Camm, Royal Standard, Emily Laxton, very fine; and Thomas Mills, which seems excellently suited for this locality. Whilst amongst Teas lovely blooms of Comtesse de Nadaillac, Homère, La Boule d'Or, Maréchal Niel, Monsieur Furtado, Souvenir de Paul Neron, Cheshunt Hybrid, and others were exhibited in fine condition.

The amateurs' classes bore unmistakeable proof of the backwardness of the season and the inclemency of the few days previous; but some of the stands were very creditable, especially those of Mr. Lewin, Mr. McMorren, and Mr. McKenzie. There was one class, however, to which exception must be taken, that of Roses in pots. We are accustomed to see these, except in very few cases, very indifferently done by amateurs, even what may be called their proper season; it was hardly to be expected, then, that in the third week in July they would be very creditable, but it seemed to me a great waste of money to bestow a prize of £5 on six plants, not one of which had a really exhibition Rose on it, a remark which applies to the other two exhibits as well; and I would suggest that for the future this class be altogether withdrawn, or else that a prize one-fifth in value be given to it, and the balance added to the prizes for cut Roses. One very interesting feature of the Show was the fact of cottagers competing for prizes in cut Roses. There can be no doubt that the success of the Society has encouraged several in the neighbourhood to attempt their growth, and a more healthy sign of good results cannot be recorded. After the Show a goodly number of exhibitors and friends (forty) met together at dinner, under the presidency of Sir Herbert Maxwell, Bart., of Monreith, a well-known scientific botanist and a great lover of herbaceous plants, some cut blooms of which he exhibited at the Show, and all passed off in the most excellent

spirit. I can say that in common with my friends Messrs. Paul & Cant we have to express our grateful recollections for much warm-hearted hospitality and kindness.—D., *Deal*.

ARTIFICIAL FERTILISERS.

I MUST disclaim the compliments paid by "A RETIRED GARDENER" to what he calls my "science," if they are meant to imply that my criticism on his practice was not founded on practice also. The fact is, we are both agreed that certain manures are useful. He cites his practice, in which enormous quantities were followed by good crops; I can cite my own, in which much smaller quantities have given equally good results, and I have confirmed that by citing also the practical experiments of Mr. Lawes, extending now over twenty years, in which the results obtained by different quantities have been most carefully compared.

"A RETIRED GARDENER" urges, however, that I have overstated the amount of guano he applied, because his rows of Peas were 5 feet apart; but I presume if he grew anything (which certainly a market gardener would do) between the rows it would have been manured in the same proportion; and I understood also that he applied the same quantities to Carrots, Onions, &c., which were, I imagine, grown closely over the ground allotted to them. I took his own figures, and assumed that they were intended to apply to full crops as well as to half crops. Next "A RETIRED GARDENER" argues that to stint manure is to waste it, and he cites the contrast between a neighbouring farm and his own garden in a droughty year; but to make the contrast accurate between the two systems of manuring the farm ought to have had the same watering for at least half as much as the garden, which I take for granted it did not. I fully admit that garden crops will bear and profit by heavier doses than field crops, and for this reason I assigned to the garden double the heaviest dose that a farmer would give to his land. Instead of recommending 3 cwt. of guano, as "A RETIRED GARDENER" seems to imply I did, merely because I said it was a common farm top-dressing, I expressly recommended for the garden a proportion which would equal 14 cwt. per acre. "A RETIRED GARDENER" adduces the heavy manuring and heavy crops of market gardeners, and I need not say that I admire their practice and its results; but these heavy manurings are almost entirely composed of stable litter with occasionally a small mixture of cow and pig dung, and we are discussing guano and nitrate of soda. The difference is this—that dung decomposes very slowly and is not available for plant food till decomposed, while a great deal of guano and the whole of nitrate of soda is instantly soluble, and is taken up into the plants as fast as their roots can absorb the water in which it is dissolved; hence dung produces an effect extending over many seasons, while the artificial manures are practically exhausted in one. Nor does even a market gardener succeed in growing any one crop to heavier weight than a single crop of roots on a farm. The difference is that he makes crop closely follow crop, and that his crops sell at higher prices; but no market gardener would ever dream of applying to any crop a dressing of a ton of guano per week to an acre!

"A RETIRED GARDENER" in truth gives up his case as to quantities when he says not only that half the dressing may be pure water, but that in a wet season he would apply the artificial manure only once or twice, while in a dry season he would apply it eight times. It is clear that if he grows crops that are "luxuriant, full, profitable," with one or two doses of manure, the extra six must be simply wasted. They were wasted, and did not in his case poison the plants, only because the water given was also so excessive. A soil from which the evaporation is checked by mulching, and which is therefore kept tolerably moist, cannot possibly absorb 2 inches of water poured on its surface. At least one-half of the water will drain away into the subsoil, and will carry with it the larger portion of the soluble matter of any manure that has been previously or simultaneously applied. This is not a scientific theory; it is a fact established by the experience of all who have examined into questions of drainage.

I may add, in reference to the remarks of Mr. Douglas, that in dry soils and seasons he prefers farm dung to artificial manures, because the former helps to retain the moisture. I entirely agree with him. On such soils artificials are only useful if a sufficient supply of water can be afforded throughout the season; but he will remember that I suggested artificials (with water when requisite) in answer to the inquiry of a gentleman who could not obtain farm manure, and who sought to know of

a substitute. That gentleman stated that during the present season he had been obliged to restrict his Roses to guano, and the high place he has taken at Rose shows seems to indicate that the substitute has been successful. Guano is, however, now-a-days of very uncertain, and often of very poor, quality; besides, it may at some seasons be too stimulating. The mixture of nitrate of soda, superphosphate of lime, and potash may be made to any strength and in any proportions desired.

If I were to presume (from some little experience with other plants) to advise such veteran Rose-growers I would say, Use during autumn neither much guano nor much nitrate of soda, but apply superphosphate and potash with just a little nitrate. This will cause growth of roots rather than of leaves, and will give firm and ripe wood and strong buds.—J. B. K.

SCOTTISH HORTICULTURAL ASSOCIATION.

THIS Association was formed at Edinburgh on the 20th of March, 1877, for the promotion and advancement of the science and practice of horticulture, and for the dissemination of a knowledge of such branches of natural history as are connected therewith.

These objects are proposed to be attained by the holding of periodical meetings for the interchange of information bearing upon these subjects, and the application of such knowledge to productive and decorative gardening, industrial economy, and the arts; by forming a museum and library suitable for the general information and reference of members; by encouraging the introduction and raising of new and meritorious plants, fruits, and vegetables, and the selection of such sorts as are suitable to the climate and soils of Britain with a view to their general cultivation.

That any person interested in the objects of the Association shall be eligible for membership, and be admitted as a member on being proposed, seconded, and duly elected by a majority present at any ordinary meeting. The annual subscription to be 2s. 6d., and payable in advance.

For 1877-78 Mr. Malcolm Dunn, Dalkeith Gardens, is President; Mr. H. Fraser, Leith Walk Nursery, Vice-President; Mr. John Methven, Leith Walk Nursery, Secretary; and Mr. David Laird, West Coates Nursery, Treasurer.

This is only a temporary statement of the aims, &c., of the Association—just sufficient to carry on the Association till the first annual meeting in March, 1878, when it will be revised and extended into laws, rules, &c., and the Association put on a proper and a permanent footing. Up to this there have been four numerous attended meetings held and various very interesting and useful papers read, the merits of which have been intelligently discussed by the members present. Eventually a summary of the papers and discussions for the use of members at a distance and the general public are hoped to be published. The Association already numbers above 150 members from all parts of the country.

NOTES AND GLEANINGS.

AMONGST the many treasures now approaching their fulness of beauty in Battersea Park—examples of both tropical and temperate vegetation—not many plants or shrubs are more effective than the GOLDEN ELDER (*Sambucus nigra* var. *aurea*). Several plants are growing in one of the large flower beds, and their bright golden foliage is very conspicuous, and has a fine contrasting effect with the dark green of the surrounding trees and shrubs. The Elder appears to have been cut down during the winter, and to this with good soil is to be attributed the healthy growth and rich golden hue of the shoots and foliage. This Elder is a very striking plant for shrubberies, and presents anything but a coarse appearance.

It cannot be too widely known that many of the DOUBLE GERANIUMS of comparatively recent introduction possess the same close and compact habit and free-flowering qualities of the single varieties. A recent inspection of Mr. Cannell's fine collection of them at Swanley affords ample proof of that being the case, and also for noting a few of the best varieties at present in cultivation. One of the most free is undoubtedly the semi-double variety Wonderful, and one of the most useful is Madame Thibaut. Very fine are Eugène Bandawin, J. C. Rodbard, C. H. Wagner, Lucie Lemoine, Député Lafize, Simon Delaux, Littré, Jean Dolfus, and Purple Emperor, new, very rich. Mdle. Amelie Ballet is the best white variety.

WHILE in most gardens walls are considered to be necessary for the ripening of TOMATOES even in the south of

England, no such sheltering aid is wanted by the London market gardeners for this crop. Tomatoes are now grown in the open quarters with apparently the same ease and certainty as Potatoes or any other crop. In one garden alone we lately saw 11,000 plants in one square, and 9000 more were growing in the same "grounds"—those of Messrs. Bagley at Fulham. The plants are in rows 3 feet apart and 18 inches between the plants. Trenches are prepared much after the manner of Celery trenches, and the plants well established and hardened are turned out of pots. The manure is used during the course of its fermentation, and the trenches are levelled-in. Each plant is trained to a short stake and is stopped when about 2 feet high, and when five or six clusters of fruit have formed no further growth of shoots is permitted. Already the fruit is of large size, and there is every prospect of a very heavy crop ripening during the season. The soil near walls and fences is considered by the market growers to be too dry and poor for Tomatoes, which are found to thrive much better in the open and highly manured fields. The variety grown resembles the Orangefield. It is surprising to notice the lavish yet profitable manner in which manure is used in these fields, nearly or quite ten times as much as is used by some agriculturists, and five times as much as is used in many gardens.

— IN 1875 we published a very favourable notice of two DOUBLE CLARKIAS—Salmon Queen and Purple King. They were raised by Mr. Hardy, seed-grower, Bures, Suffolk. He has sent us specimens of this year's growth of the same variety, and we can testify they are very fine.

— MR. J. LINDSAY, gardener, enclosed to us a spray of a GREEN ROSE. It has been grown in the gardens of Wybrants Ophert, Esq., Ballyconnell House, Falcarragh, Co. Donegal, for the last eight or ten years. Its entire green colour is not attractive. In growth and foliage it is described as neat and pleasing. It is a good example of *R. viridiflora*.

— VILLA GARDENS are yearly growing in numbers. Small enclosures of a few rods of ground, or even a few yards, frequently afford much pleasure to their owners and yield also instruction to visitors. One of the latest instances—not, perhaps, of the mere attractiveness of a villa garden, but of its value to the owner and the general interest attaching to it which has come under our notice—is that of W. Clifton, Esq., at Fulham. Mr. Clifton is a gentleman who has long been engaged in matters connected with the public service, and he has brought his scientific attainments to bear on the management of his garden. His residence is half surrounded with a capacious glass structure, and from this he has had the honour of having out and forwarded to Her Majesty nine hundred blooms of *Devoniensis* Rose in one week. That was some years ago; and Roses are not grown now, but instead Tuberoses, Begonias, Lilliums, Hippeastrums, Phloxes, &c., are cultivated and increased. Phloxes are grown by hundreds—home-raised seedlings. These are very varied in colour, and it is worthy of note that one variety has been exclusively relied on as the seed-bearing parent. Many varieties are very good, and as flowering in pots and growing in semi-wild luxuriance in the garden produce an excellent effect. Several Geraniums have been raised in Mr. Clifton's garden, amongst them the excellent golden bicolor Crown Prince. The outside garden is also noteworthy. It is not a trim and formal enclosure designed on geometrical principles and ornamented with carpet beds; on the contrary, it is as informal as a garden can be. The centre has been hollowed out, and contains a little water, little lawns, several beds of shrubs, and a thicket of Conifers. Wellingtonias raised from cuttings in 1861 are now fine trees, equal if not superior to those raised from seed. There are many kinds of Conifers, and almost every tree has a history. There are dozens of Hollies raised from seed by the owner and now laden with berries. The shrubs and trees cannot be particularised, but a variety of the *Deodar* demands mention—*Cedrus Deodara robusta*. It is most striking and handsome; the main branches being as close, flat, and dense as those of the Cedar of Lebanon, while the terminal growths are almost fountain-like by their graceful drooping character. *C. africana* is also very fine. Mr. Clifton with the aid of his clever young gardener "Bill" (Mr. W. Chisholm) proves how varied and interesting a villa garden may become when it is intelligently managed.

— We have received the schedule of the NATIONAL CAR-NATION AND PICOTEE SOCIETY'S SHOW, which is to be held in the Botanical Gardens, Manchester, on August 4th, 5th, and

6th. The classes are not quite so numerous nor the prizes so large as those provided for the southern show recently held at the Westminster Aquarium. Many northern florists—to their honour be it said—appear to be prompted by a real earnest love for their flowers rather than tempted by high prizes for their cultivation; hence good exhibitions result, the last of which we trust will be the best. In order to secure uniformity in the stands the Hon. Sec., the Rev. F. D. Horner, requests that the standard of dimensions given below, which was discussed at the general meeting in January, 1876, will be adopted by all the exhibitors this year. The collections of twelve must be shown in boxes of three fours, of the following dimensions—viz., from centre to centre, 3½ inches; from centre to outside, 2½ inches; outside length, 15½ inches; width, 12 inches; depth, 4½ inches; to be painted a bright green. The collections of six blooms, in boxes of three twos, of similar distances with those of the twelve-blooms class. An unregulated size of stands interferes seriously with the good effect of the show; and this matter is now upon so prominent a footing that flowers shown on stands not in accordance with the Society's regulations are liable to disqualification.

— THE KIDDERMINSTER HORTICULTURAL EXHIBITION, which closed on the 26th ult., was, we are informed, very successful. The exhibits were not only numerous but of superior quality. Nearly £200 were offered in prizes. The chief winners in the plant classes were Mr. Tudgey, gardener to J. F. W. Williams, Esq.; Mr. Cypher and Mr. Pilgrim, Cheltenham; and Mr. Plevy, gardener to E. J. Morton, Esq. In the fruit classes Mr. Cox, gardener to Earl Beauchamp; Mr. Moffatt, gardener to H. Alsopp, Esq.; Mr. Child, gardener to the Earl of Coventry, were successful exhibitors. Vegetables were very good, especially Potatoes. Carter's Main Crop, Snowflake, Early Rose, Mona's Pride, and the Emperor were the leading varieties.

— ONE of the most graceful and effective of flowering shrubs for imparting an air of lightness and cheerfulness to the prevailing greenness of shrubberies in July is *SPIRÆA ARLEFOLIA*. This *Spiræa* is profusely laden with its elegant pearl-white flowers in summer, as is the *Deutzia* in the spring. A valuable quality possessed by this *Spiræa* is that it grows and flowers freely under the shade of trees. Our attention was drawn to this fact by Mr. Harding, gardener to Rev. W. Arthur, Clapham Common, who pointed out a shrub growing under the dense shade of some large Elms, and which was flowering with the greatest freedom. Mr. Harding, who has a large acquaintance with hardy flowers and shrubs, esteems *Spiræa aralefolia* as one of the most useful for cultivation in sun or in shade, and for affording a great supply of elegant sprays for vase and room decoration.

— WE remarked a few weeks ago on the probability of false alarms being heard of the advent of the COLORADO BEETLE into this country. An alarm of this nature has originated at Hereford, where the dreaded beetle turns out to be the gardeners' friend, the ladybird. The Potato beetle, as everyone ought to know, is not spotted like the lady-bird, but is clearly marked with ten stripes down its wing cases. When we published in 1874 an engraving of the Colorado beetle a correspondent predicted that if the pest arrived in this country it would probably be in the pupa state, or some enthusiastic naturalist would nurse over some precious specimens and expect a medal for his pains. The members of the York Chamber of Agriculture do not appear to regard the last-named source of danger an empty one, for at a recent meeting the following resolution was proposed and carried:—"Considering the danger to which we are exposed from the ravages of the insect in question, it is to be regretted that over-zealous naturalists are having beetles brought over alive from America, and are keeping and experimenting with them as to their habits and the food they will eat." The best means of becoming acquainted with the appearance of the beetle is by obtaining models of it from Mr. Louis Stollwerck, 145, Cannon Street, London. The insect in its various stages is more clearly represented by these models than by illustrations.

— SHORTLY after the Kirkcudbright Flower Show was opened to the public last week Lord Selkirk presented a handsome marble timepiece to Mr. JAMES SERVICE, nurseryman, along with a silver teapot for Mrs. Service, in acknowledgment of the hearty interest which he had always taken in the exhibitions, and of his exertions to promote their success. His lordship remarked that he understood Mr. Service had been one of the most zealous promoters of these exhibitions, and

he thought it alike honourable to himself and creditable to his brother horticulturists that his exertions should be thus publicly acknowledged. He had the greatest pleasure in making the presentation. The plate upon the timepiece bore the following inscription:—"Presented to Mr. James Service, nurseryman, Maxwelltown, Dumfries, as a mark of respect by a few friends. Kirkcudbright, 20th July, 1877." This pleasing mark of recognition was appropriately acknowledged by Mr. Service.

— In alluding to the VINEYARD AT CASTLE COCH, "The Gardener" states, the Vines planted in the spring of 1875 in the Marquis of Bute's vineyard are looking remarkably well, and there is every appearance of their carrying a good crop. Each plant has from three to four strong shoots, and each shoot showed two bunches of Grapes. The experiment which Lord Bute determined on making two years ago will probably be tested in some degree this year, as it is intended to allow the plants to mature three or four bunches of Grapes each. Judging from present appearance they will do this easily. M. Chauvenet, a vineyard proprietor from the Côte d'Or, France, has been on a visit to Castle Coch, and expresses a very favourable opinion. He thinks the site and soil all that could be desired, and states that the Vines are looking as well, and are quite as forward as those in his own vineyard at Nuits; and he believes, from what he has seen, that the experiment will turn out satisfactory. We understand that M. Chauvenet will visit Cardiff again in the autumn to give the benefit of his experience in wine-making; and we sincerely hope that before many years have elapsed we shall have the opportunity of tasting wines of home growth.

— *LILIUM LONGIFLORUM* var. *EXIMUM* we observe in fine condition on entering the temperate house at Kew, and believe it to be one of the best for pot culture. Its large white flowers are scarcely to be surpassed for beauty, and the sweet perfume has not the overpowering strength of *L. auratum*. The *Victoria regia* commenced flowering some days ago, and on the roof of the house is a splendid yellow-flowered climber growing with great vigour and profusion of bloom. This is *Adenocalymna nitidum*; it is allied to *Bignonia*, and the flowers are of large size. *Cyrtodeira fulgida* is one of the most striking of all plants in flower; its leaves are of dark metallic hue, relieved with white along the midrib and principal veins, and the flowers are deep scarlet. This plant is growing in the stove, and, though doing well with pot culture, would evidently be very fine as a basket plant. *Bomarea Carderi* is blooming with fine effect in the succulent house. It was introduced at the Royal Gardens and also by Mr. W. Bull, whose plants have this summer been exhibited in flower. One of the umbels has about thirty-two flowers, the majority expanded, while the others remain as pretty pink buds. The perianth or coloured portion here measures in length nearly 2½ inches, the outer segments pink, and the inner green, with black-purple spots. The *Bomarea*s are sometimes grown in pots, but appear to reach a much better development if planted out.

— AMONGST hardy flowering shrubs *HYDRANGÆA PANICULATA GRANDIFLORA* is one of the most effective. We first saw this *Hydrangæa* flowering in the nurseries of Mr. Charles Van Geert at Antwerp. We have since seen it in several nurseries and in some private gardens in England, and in every instance it was generally admired. It appears to be perfectly hardy, grows freely in good soil, and flowers with the greatest profusion. It is particularly suitable for planting amongst shrubs near the margin of the borders, and in such a position it is highly effective. It is a little surprising that this *Hydrangæa* is not more extensively cultivated, since plants of it are now plentiful and can be purchased at a cheap rate.

OUR BORDER FLOWERS—DAY LILY.

DAY LILIES are quite at home with us in our borders: they are capital plants for filling-up waste places, for they are not particular as to soil or situation provided they have a moderate share of light and air, yet they enjoy partial shade. Many years have passed away since they first found their way to our shores, and I venture to say that had they been an expensive delicate race of plants they would have found favour and in all probability been extensively cultivated, but bearing any amount of rough usage they are thrust into corners often nearly out of sight.

To see them in perfection they must have space afforded them, and the better they are treated the greater is their

beauty. They are rapid-growing plants, and should have a good depth of soil for their roots; they are moisture-loving plants, but the water must not be stagnant. A compost of two parts good sandy loam, one part peat, one part well-decomposed vegetable matter, and a little coarse sand will meet their requirements. They are useful in pots for any purpose. When well done a plant in a good-sized pot having twenty or more flower scapes, plunged and in the centre of a large bed or other conspicuous place on the lawn, is a grand object when in full bloom. They are effective too for indoor decoration, and for cut flowers also.

Beautiful as are *Hemerocallis flava*, *fulva*, *graminea*, *japonica*, *disticha*, and *Dumortieri*, they are far surpassed by the double and variegated kinds. They are best increased by division when growth has commenced in spring.—*VERITAS*.

PARAFFIN OIL VERSUS THE PARSLEY GRUB.

ABOUT a month ago a long row of Parsley in the kitchen garden here became quite yellow in the leaves, and showed every sign of being badly attacked with worms at the root. I mixed a wine-glassful of paraffin to every six gallons of water, and gave the row a thorough watering. The result is that the plants are growing vigorously, and to see them now no one would ever think they had been so nearly killed a month ago. There is no vegetable suffers more from insects at the root than Parsley. I could name many good gardens where it fails every year through the same cause. Wherever it is failing now I would advise an immediate application of paraffin.—*A KITCHEN GARDENER*.

THE NETTLE.

THE Nettle is not a popular plant. Most persons, indeed, cherish for it a deep-seated dislike, declaring that it adds dreariness to the waste places which it frequents, and that it repels every advance to friendship by its sharp sting and acrid juices. These allegations are partially true, yet it has somewhat to say in its own behalf. In the first place it is extremely well connected. It belongs to the same family as the Hop, the Hemp, and the Mulberry, claims kindred with the whole Fig tribe, so rich in fruit and rubbers, and is allied to the Banyan, most wonderful of reproducing growths, and to the Upas of Java, though, perhaps, the less said about that the better. It dwells in desolate places because others are denied it, but it clothes them with life and colour and the graces of poetic association. More than a score of insects are nourished solely by it, among them some of the most gorgeous butterflies that ever played in the summer sun; and, although its leaves are somewhat coarse, it brings to mind Chaucer and Waller and the gentle Ophelia, wreathed with

"Corn Flowers, Nettles, Daisies, and long Purples."

Though not prepossessing to the unassisted eye, it bears, and, indeed, courts minute inspection, its dense and slender hairs when seen through the microscope exciting admiration and amazement by their wonderfully curious mechanism. Though this delicate and yielding armour, lightly touched and languidly toyed with, is venomous, it loses its power to harm when firmly grasped, and the plant, rich in soothing as in irritating properties, allays the burning of its wounds by its own healing juices. In many localities, also, it grows in company with, or not far from, the Dock (*Rumex*), which is an antidote to its poison. Children increase, as they think, the potency of the latter by repeating during its application the antique charm:—

"Nettle in, Dock out,
Dock in, Nettle out,
Nettle in, Dock out,
Dock rub Nettle out."

That the Nettle may be useful as a pot-herb is proved by the old Scotch song:—

"Gin ye be for lang kail,
Cow [pluck] the Nettle early;
Gin ye be for lang kail,
Cow the Nettle early."

"Cow it laigh, cowe it snne,
Cow it in the month of June,
Just when it is in the blume,
Cow the Nettle early."

From the fibres of this plant the French manufacture good paper, the Kamchatkans fishing-lines, and the Hindostanees a delicate and famous cloth. Its roots boiled with alum

afford a yellow dye, and the juice of the stalks and leaves impart to woollen stuffs a pleasing and permanent green; and in the north of Europe it is grown as fodder for cows, and cut several times in the year. In many places it is highly valued as food for swine, and the chopped leaves are eagerly eaten by poultry, especially by young turkeys, to whom they are a luxury. One species of the genus produces tubers, which form in India an article of diet either raw or cooked. Australia presents us with a tree Nettle, which sometimes reaches a height of 140 feet, with a trunk of proportional thickness.

The Nettle is known to heraldry through the family of Malherbe, whose armorial bearings were three Nettle leaves proper; to history through the Romans, who are said to have carried it to England with their arts and arms; and to legendary literature through the founder of the Rhine castle of Eberstein.

THE INDIGO PLANT (*INDIGOFERA TINCTORIA*).

ANNUALLY there is an indigo planters' dinner at Calcutta, and several of those dinners were enjoyed about thirty years

Fig. 22.—*Indigofera tinctoria*.

since. The planters came down the Ganges, and we have portraits of them examining sedulously samples of the purple dye.

The uncertainty of the indigo crop is as proverbial as that from the Hop plants in England.

In Bengal, the crop is particularly subject to be destroyed by the annual inundation of the river, if it occurs earlier than usual. A storm of wind, accompanied by rain and hail, as completely ruins the crop as if devoured by the locust; neither from this latter scourge is the crop exempt.

This proneness to injury extends throughout its growth. The seedlings are liable to be destroyed by an insect closely resembling the Turnip fly, as well as by the frog. Caterpillars feed upon the leaves of older plants, and the white ant destroys them by consuming their roots.

To these destructive visitations are to be added the more than ordinary liability of the plant to injury, not merely from at-

mospheric commotions, but even from apparently less inimical visitations. Thus, not only do storms of wind, heavy rains, and hail destroy the indigo planter's prospects, but even sunshine, if it pours out fervently after showers of rain, is apt to scorch the plants; and if it occurs during the first month of their growth is most injurious to their future advance.

The reason of this effect appears to be the violent change from a state of imbibing to a rapid transpiration of moisture.

The *Indigofera tinctoria* belongs to the natural order Leguminosæ, and the Linnean class and order Diadelphia Decandria. Its leaves are pinnate, its stem shrubby and erect; its flowers in racemes are pale with a red keel and vexillum.

THE AMERICAN POPLAR (*Anglice*, TULIP TREE), *LIRIODENDRON TULIPIFERA*.

THIS is by far the finest tree in our forest. Nowhere does the Poplar attain greater dimensions than in West Virginia. It often reaches the height of 120 to 140 feet, and the diameter of 7 to 8 and 9 feet, with a distance of 80 feet from the first limb. Several trees are reported as 10 and 11 feet in diameter in this state. It delights in deep loamy and extremely fertile soils, such as are found in rich bottoms and on rivers or swamps. It will grow, however, on soil of different kinds, but has its timber affected accordingly. A deep sandy loam seems best for it. To attain the greatest size it must be sheltered from the high winds, and at the same time have light and air enough to ripen its wood. It is generally propagated by the seeds. The timber, though classed among the light woods, is yet much heavier than the true Poplar, for this tree is properly called Tulip Tree, and not Poplar. Its grain is fine, rather compact, polishes well, and is easily wrought. When dry a cubic foot weighs 25 lbs. It affords excellent charcoal, yielding 22 per cent. The heart-wood, perfectly seasoned, long resists the action of the weather, and is rarely attacked by insects. When not perfectly seasoned, however, it is apt to warp under alternations of dryness and moisture. The nature of the soil on which it grows has a striking effect on the colour and quality of the wood. Mechanics distinguish three kinds—white, blue, and yellow. No external marks will distinguish them positively. In general, the white Poplar grows on dry, gravelly, elevated ground, and has a branchy summit with a small amount of heart-wood. The grain is coarser and harder and the wood decays more rapidly. The blue has the same general character. The yellow Poplar is by far the finest kind, and has all the qualities required for a great variety of uses. It would take too much space merely to enumerate all of these. It is used extensively in the interior of houses for shingles and for weather-boarding. Large quantities are used in making trunks covered with cloth or skins; for tables, bedsteads, seats of chairs, &c.; for the supports of veneers, inner work of bureaus, &c.; in winnowing machines; for bowls, broom handles, rails, and planking for fences; for the backing of picture frames, looking-glasses, &c., it is employed. The bark of the tree is considered by some hardly inferior as an antiseptic and tonic to the Cinchona. The aromatic principle resides in a resinous matter in the bark, and when used stimulates the intestinal canal and acts as a gentle cathartic. In many instances the stomach cannot support it unless accompanied with a few drops of laudanum. The bark, mixed with an equal amount of dogwood and steeped in whisky, forms a tincture used as a remedy for intermittent fever. The bark reduced to powder and given to horses is a pretty sure remedy for worms. The Poplar is one of the most generally diffused and abundant trees in the State. Great quantities of the finest trees are to be found in the central and southern counties. Perhaps some of the largest timber is met with on the affluents of the New, and Kanawha, and the Big Sandy rivers.—BURNET LANDBETH, Philadelphia, U.S.A. (in *Journal of Forestry*).

DISTINGUISHED BOTANICAL TRAVELLERS.

No. 1.

DAVID DOUGLAS.

DAVID DOUGLAS was born at Scone, in Perthshire, in 1798, where his father was a working mason. He received a plain education at the parish school of Kinnoul, and was early placed as an apprentice in the garden of the Earl of Mansfield at Scone Palace. As a lad he was remarkable for his fondness for books and the study of plants. In the winter he devoted his evenings to reading, and in the summer to making botanical excursions for the purpose of collecting the wild plants of

the neighbourhood. In 1818 he went to live at Valleyfield, the seat of Sir Robert Preston, Bart., whose garden was then celebrated for its choice collection of exotic plants. Here he was treated by the head gardener, Mr. Stewart, with great kindness, who procured him access to Sir Robert's valuable botanical library. From Valleyfield he removed to Glasgow, where he was employed in the Botanic Garden of the University. His intelligence attracted the attention of Dr. (afterwards Sir William) Hooker, then professor of botany at Glasgow, and he made him his companion in his botanical excursions for the purpose of collecting materials for his "Flora Scotica." By Sir William Hooker he was recom-

mended to the Horticultural Society of London as a botanical collector, and in 1823 he was sent to the United States, where he procured many fine plants, and greatly increased the collection of fruit trees in the possession of the Society. In 1824 he was sent by the Horticultural Society to explore the vegetable productions of the country adjoining the Columbia River and southwards towards California. The vessel in which he went out touched at Rio de Janeiro, where he collected many rare Orchidaceous plants and bulbs. In the course of his voyage round Cape Horn he shot many rare and curious birds. He visited the island of Juan Fernandez, which he describes as "an enchanting spot, being fertile and delight-

Fig. 23.—MR. DAVID DOUGLAS.

fully wooded." Here he sowed a quantity of garden seed, with the wish, he says, that he might add "to the collection of a second Robinson Crusoe, should one appear." He arrived at Fort Vancouver on the Columbia River in April, 1825. During his journey he sent home from time to time large numbers of beautiful plants, with seeds and dried specimens. Of the genus *Pinus* he discovered several species of gigantic size, one of which has been named after himself, *P. Douglasii*. In the spring of 1827 he went from Fort Vancouver across the Rocky Mountains to Hudson's Bay, where he met Captain (afterwards Sir John) Franklin, Dr. Richardson, and Captain (afterwards Sir George) Back, returning from their overland Arctic expedition. With these travellers he returned to England, bringing with him the result of his researches. Shortly after his return he was elected, free of expense, Fellow of the Linnean, Zoological, and Geological Societies. He

remained in London two years, and sailed again for the Columbia River in 1829. He afterwards went to the Sandwich Islands, where he had remained some months when an accident put an end to his existence. The natives of the Sandwich Islands are in the habit of making pits, in which they catch the wild bulls. In one of his excursions Mr. Douglas fell accidentally into one of these pits, in which an infuriated animal was already trapped. The animal attacked him, and he was found dreadfully mutilated and quite dead. This occurred on the 12th of July, 1834.

THE ROSE ELECTION AND ROSES.

SEVERAL letters have appeared, and I have also had one or two privately disapproving the suggestion of restricting the naming of similar Roses like *Mlle. Marie Finger* and *Eugénie Verdier*.

As it is essential we should agree, I have determined to withdraw the idea. Being the child of "WILD SAVAGE" and myself, of course we thought a great deal of it; though, as regards the two Roses above named, they are so beautiful and the colour so exquisite when fresh, that I should be rather glad of the excuse that two should be in the forty-eight. I take Mlle. Finger to be rather deeper, and certainly a better grower than her older sister.

Thanks to Mr. Curtis for hints about cutting Roses for exhibition. I cannot help thinking that certain Roses will grow in a stand after cutting, whilst others do not seem to move, though apparently cut under similar conditions. Amongst the growers I fancy are Baronne de Rothschild and François Michélon. Some Roses again keep their fresh colours, whilst others almost immediately look lustreless. A startling instance of the latter is Paul Neron: an hour or two after cutting, its beauty (and though coarse it is sometimes beautiful) vanishes, and the colour is dull, and coarseness with dulness of colour is fatal, hence it never appears to me to improve a stand.—JOSEPH HINTON, *Warminster*.

ROYAL HORTICULTURAL SOCIETY.

REPORTS ON FRUITS, FLOWERS, AND VEGETABLES AT CHISWICK.

A MEETING of the Fruit Committee was held on July 24th at Chiswick to examine subjects grown for trial there this season. Henry Webb, Esq., in the chair.

THE GOOSEBERRIES, of which there is an extensive collection growing, were first examined, a small basket of each variety (two hundred in number) having been gathered for comparison and classification. The Committee selected the following varieties as especially worthy of cultivation—viz., *Reds*: Red Champagne, Warrington, Monarch, and Starling. *Green*: Roseberry, Overall, Green Globe, Pitmaston Green Gage, Cheshire Lady, Shiner, and Gretna Green. *Whites*: Whitesmith, Orleans, Keepsake, Safety, and Top Gallant. *Yellow*: Sulphur, Rumbullion, Aston Hepburn, and Yellow Globe.

RED CURRANTS—These were examined with great care as to their nomenclature, so much confusion still existing amongst them in that respect. Of the most approved varieties noted the earliest and the largest is the *Red Cherry*, which has the following synonyms—viz., Bertin No. 9, Grosse Rouge de Boulogne, Fertile d'Angleterre, La Hâtive, La Fertile, Fertile de Bertin, Hâtive de Bertin, Chenonceau, Belle de St. Gilles, Fertile, Fertile de Palluau, and La Versaillaise.

The *Red Dutch*, which is the variety most generally cultivated in gardens, rejoices in the following synonyms:—Knight's Large Red, Knight's Sweet Red, Goliath, Fielder's Red, Palmer's Late Red, Pitmaston Red, Pitmaston Prolific, Large Sweet Red, Bertin No. 1, Dancer's Selected, and Jackson's Mammoth.

The *Red Grape*, a long-bunched sort, of a pale red. Synonyms:—Rouge Transparent, Queen Victoria, Fertile de Palluau.

Houghton Castle, the best constitutioned variety. Synonyms:—Houghton Seedling, Orangefield. A fuller report of these will appear in the Society's Journal.

An examination of the Turnips, of which about 150 varieties are this season being grown, was then made, and the earliest was the Green Strap Leaf (Carter & Co.). Tomatoes were also examined, a very large collection of which is being cultivated in pots, the only one showing signs of ripening being *Early Gem*, sent by Messrs. Veitch & Sons. Of these a later examination will be made.

A meeting of the Floral Committee was held at Chiswick on July 25th—George F. Wilson, Esq., in the chair—for the examination of the various collections of plants growing in the gardens for trial this season.

1, ZONAL PELARGONIUMS.—Of these a large selection of the most approved newer varieties which were grown in pots last season have been bedded-out along with some of the best older sorts for comparison. First-class certificates were awarded to Mr. J. R. Pearson for Atlas, a large-trussed crimson scarlet Nosegay; Rev. A. Atkinson, crimson scarlet. To Messrs. James Cocker & Sons for John Fraser, light magenta. To Mr. J. George for Mrs. J. George, rosy cerise; and Beauty of Surrey, crimson scarlet, very free, and excellent habit. Of the older varieties conspicuous for their excellence were noted Vesuvius, Princess of Wales, Vesta, Cleopatra, Violet Hill Nosegay, and Claude de la Meurthe, &c. Of the newer varieties which have been sent out this season, and grown in pots under glass, first-class certificates were awarded to Mr. J. R. Pearson for Rebecca, a very beautiful magenta scarlet Nosegay; Louisa, a

sort of shaded magenta pink, mottled with rose; Blanche Gordon, light pink. To Mr. J. George for Lord Mayo, bright scarlet. Specially noticeable also were Miss Wakefield, Lizzie Brooks, and Lord Giffard.

2, BEDDING VIOLAS.—A large collection of those reported on last year are again under cultivation, the most noticeable amongst them being Crown Jewel (Grieve), Blue Beard, Blue Bell, Queen of Lilacs, Lilacina, Rubra Lilacina, Princess Teck, and Pilgrimage Park. Of new varieties first-class certificates were awarded to Mr. R. Dean for Vestal, a pure white variety of a fine free habit; to Messrs. Dickson & Co. for Holyrood, a very rich dark blue variety of good habit; to Mr. Fromow for Golden Prince, a clear yellow variety with distinct white eye.

3, BEGONIAS.—A fair selection of these have been grown in pots, chiefly of the tuberous-rooted class, the most striking being Aome and Kalista (Veitch), Froebel, &c. A first-class certificate was awarded to a seedling from *roseiflora* raised at Chiswick, and named by the Committee Mrs. Barron. It is of very robust growth, forming a large plant; flowers large, roundish, and produced freely, of a pale rosy pink: a very distinct sort. Moonlight, a hybrid raised by Col. Clarke and certificated last year, is exceedingly attractive. This, which is something of the habit of *Weltoniensis* and producing long racemes of pure white flowers, will become a very popular decorative plant.

4, FUCHSIAS.—Of these a selected collection has been grown, occupying one house. A first-class certificate was awarded to Messrs. Laing & Co. for Lord Beaconsfield, a hybrid from the old Fulgens, and possessing a good deal of its character. As a free-blooming decorative plant it will prove very valuable. Very conspicuous amongst others is Champion of the World, a very large dark double sort—almost a monster.

5, VERBENAS.—Only a few varieties of these are on trial. For habit Purple King still stands pre-eminent. Blue Bell (Smith) is very effective. A first-class certificate was awarded to Mr. John Fraser for Carl Sieglig, an intensely dark blue variety of good habit.

6, HARDY ANNUALS.—Complete collections of Iberises, Clarkias, Godetias, Viscarias, Dianthus, Stocks, Balsams, &c., are on trial this season, and when in full flower are exceedingly showy. Of Iberis first-class certificates were awarded to Messrs. Vilmorin et Cie. for two splendid novelties—viz., I. coronata hybrida nana rosea, a variety of fine dwarf growth with large rosy salmon flowers, not unlike gibraltaria and exceedingly beautiful; I. coronata hybrida nana alba, a variety of the same character with pure white flowers. Amongst the Godetias Lady Albemarle, which was certificated last year, is by far the finest. Of Viscarias none exceed in beauty the true V. cardinalis.

Mr. Charles Turner, Royal Nurseries, Slough, sent cut blooms of his seedling Roses Penelope Mayo and Harrison Weir. This latter variety is of a rich dark crimson colour, and is a promising variety. The Committee highly recommended it, at the same time requesting that it be again brought before them, being unable to give a final decision from seeing only one bloom.

RESULTS OF PEAR AND APPLE CULTURE.

In the year 1864 I bought a small piece of land with the view of building a domicile; and as no residence is complete without a garden and a few fruit trees, and having the adage impressed on my mind, "Who plants Pears plants for his heirs," and being then approaching if not quite arrived at middle age, I began to look about me for some course to adopt to enjoy the present produce. Chance introduced "Rivers' Miniature Fruit Garden" to my notice, and I there found the system that was likely to answer my purpose, for it promised immediate results.

I bought and planted some fifty or sixty miniature Pear and Apple trees, bushes and pyramids, which have since been added to, making my number of trees altogether upwards of three hundred—Pears, standards and pyramids, 103; trained trees, 10; Apples, pyramids and bushes, 80. These are in a bearing state, ten years old and upwards. Younger trees and grafts, 128: total, 321. As I stated in my letter about Roses the soil is a light gravelly one, subsoil dry gravel. In planting the Pears care was taken to dress the soil richly with manure, and in the case of Apples to select the most loamy soil. Some loam brought from elsewhere has been added.

The trees were originally planted about 3 feet apart. They have been summer-pinned, root-pruned, and shifted in the

manner recommended by Mr. Rivers, and they are now on the average about 5 or 6 feet apart, the most vigorous trees having reached 7 or 8 feet in height and about 4 feet through; others retain the more dwarf character, more resembling in size a large Currant or Gooseberry bush. The result has been eminently satisfactory, I can scarcely up to this year record any failures in amount of produce. Some sorts have of course been more productive than others, but I have not, on account of using them for my table, had a systematic account of the produce taken, but I intend to do so this year. I extract from my memoranda the following account:—

In 1875 one Nonesuch Apple tree produced four gallons of fruit; 1876, three Beurré Superfin Pears produced half a bushel, ninety-four in number; five Marie Louise, bushes, six gallons and a half; one Marie Louise d'Ucele had sixty fruit, 29 lbs. in weight; one ditto, twenty-two fruit, 13 lbs. 12 ozs.; one Catillac, forty-nine fruit, 33 lbs. 14 ozs.; one ditto, sixty-two fruit, 47 lbs. 11 ozs. Of the 103 small Pear trees and ten trained I have had thirty-eight failures this year, but the crop of the remainder shows such a large promise that I still consider the year a favourable one. I enumerate the failures below—five Winter Nelis, apprehended cause of failure, overbloom and bleak winds; four Beurré Superfin, the same; one Uvedale's St. Germain, soil and climate does not suit; one Williams' Bon Chrétien, accidental; five Marie Louise and seven Joséphine de Malines, overbearing and want of vigour; two Chaumontel, cannot account for; one Marie Louise d'Ucele, previous overbearing; three Colmar Van Mons, ditto; two Easter Beurré, want of vigour. Pears discarded on account of soil or climate not suiting their growth—Gluon Morcean, Beurré d'Aremberg, and Uvedale's St. Germain, always cracked, did not ripen, and were affected with rust and spots; Winter Nelis, blossomed very freely, but fruit if set failed to hold. In addition to the failures in the Pears stated above, and the causes to which such failures are attributed, may be added the severe winds and frosts of the latter end of April and beginning of May this year.

I append a list of the sorts of Pears and Apples I have cultivated with success, with notes on the crop of this year.

Pears.—Doyenné d'Été, full crop; Jargonelle, full crop; Williams' Bon Chrétien, full crop from three trees; Beurré d'Amanlis, full crop; Colmar d'Été, immense crop, has required much thinning; Louise Bonne of Jersey, good crop from three trained trees; Marie Louise, good crop from one trained tree; Marie Louise d'Ucele, immense crop from four trees; Gansel's Bergamot, good crop; Huyshe's Victoria, good crop; Chaumontel, immense crop from six bushes; Beurré Diel, good crop; Joséphine de Malines, failure this year, ordinarily good; Ne Plus Meuris, good crop; Bergamotte Espéren, immense cropper (see notes on thinning); Easter Beurré, good crop; Catillac, failure this year, generally good; Colmar Van Mons, failure.

Apples.—Pitmaston Pine, King of the Pippins, Cox's Orange Pippin, Cox's Pomona, Ribston Pippin, Northern Spy, Keswick Codlin, Nonesuch, Blenheim Orange, Guernsey Pippin, and Flanders Pippin. All these have a good crop this year, and have in many instances required vigorous thinning.

I have been in the habit of thinning the fruit, and this I consider a very important part of culture, as allowing the trees to overbear themselves weakens them and takes away from the quality of the fruit. As an example: from one tree of Bergamotte Espéren, about 7 feet high and not more than 4 feet through, I removed last week 117 Pears about the size of a walnut, leaving quite enough on to ripen. The fruit will be larger and the trees not distressed, and also less liable to be attacked by insects. I observe that the grub always attacks at the points of contact. A Pear bored into is ruined; it will not keep to ripen, but rots. I never leave two fruits on one spur. I have been in the habit also of disbudding when the tree has shown evidence of blooming too strongly. I believe the production of an excess of pollen is injurious to the tree; I have noticed that more fruit sets from a moderate blossoming than from an excessive one. I take care with regard to pruning to remove in the spring any unripe wood of the previous season, as it is worse than useless.

With regard to Apples I have much fewer failures to record this year than on the Pear trees. Of the eighty Apples in bearing not more than six have proved total failures, and this I do not attribute to the weather during blooming, but rather to other causes needless to mention. With regard both to Pears and Apples I have followed strictly the rules laid down by Mr. Rivers—summer-pinching, shifting, and root-pruning;

mulching with good stable manure, and watering during the very dry summers we have had sometimes of late. The trees have had no protection from the frost. I extract from my memoranda, April 12th, 1876—Snowstorm, Pear blossom entirely covered with 2 inches of snow, yet I had an excellent crop last year.—A CONSTANT SUBSCRIBER, *Alverstoke, Hants.*

ROYAL AQUARIUM NATIONAL CARNATION AND PICOTEE SHOW.

In all respects the Exhibition surpassed the anticipations of its promoters. The date could not easily be altered, and within a few weeks of the show the most experienced growers thought that the best collections in the south could not be in in time. Mr. Turner was a week too late, and the best flowers of Mr. Dodwell's collection I hear were not in. High praise is due to Mr. Robertson, the Manager of the Royal Aquarium, for the manner in which the promoters of the Exhibition were entertained by him, and for the excellent arrangements made for the convenience of both exhibitors and judges.

All the classes were well filled; in some of them as many as six prizes were awarded to the same number of exhibitors. As in the case of the National Auricula Show, lovers of the flowers came from distant parts, and all of them, as far as I could learn, were well pleased with what they saw. The only drawback was the fact that the flowers had suffered considerably from the gas, and those who came the second day did not see them at their best. If a two-days show is held next year lovers of the flowers would do well to visit the exhibition on the first day.

I looked over the stands after the judging and made a few notes of the best flowers. Beginning with Scarlet Bizarres, there was nothing to surpass the old flowers that we have grown and loved for many years. Admiral Curzon (Easom) was at the head of the class. True Briton (Hepworth) in my stand of twenty-four was very fine indeed, and Dreadnought (Daniels) was but little behind the premier flower. In Crimson Bizarres there is a considerable advance on the old flowers. I am not sure whether a new flower sent out in the autumn of last year will not head the list. I have it now fine indeed, but being of the Jenny Lind stock it is late and I could not cut it for the show. The name is John Simonite (Simonite); the markings are brighter by far than in any other flower, and the guard petals are beautifully cupped and smooth on the edge. Rainbow (Bertram) was exhibited in the stand of the raiser, and is also superb. Only one flower was exhibited; if two had been put up the variety must have been honoured by a first-class certificate, a rule of the Society forbidding awards to be made to a single flower. J. D. Hextall (Simonite) was also shown in fine form; no collection is complete without it. Lord Raglan (Bowers) was fine, the colours being very brilliant, full of life and beauty. These were all the newest and best in this class.

We now come to the Pink and Purple Bizarres, the weakest class, where Sarah Payne (Ward), a lovely flower, was the best. Next to it came James Taylor (Gibbons), a smaller flower, but even more striking in its regular and well-defined markings. Falconbridge (May) was also good as shown. A new flower not yet in commerce, named Satisfaction, was shown in my stand of twelve. Mr. Rudd says of it, "Pale in its colours, but in form, habit, and rich lustrous white a perfect gem." Raised by Mr. T. Bowers.

Purple Flakes were well represented, and at the head of the list I must place James Douglas (Simonite). The purple is very bright, and the formation of the flower is not surpassed by any in the class. Premier (Milwood) was very fine in my stand. In Mr. Turner's collection I noted as being of great merit Florence Nightingale (Sealey), and Squire Trow (Jackson).

Scarlet Flakes were also well represented. Prominent was Sportsman (Hedderly), certainly the best in its class. Next to it I must place Clipper (Fletcher), shown in London for the first time; in my stand of twenty-four was a fine specimen of it. Marmion (Bertram) is quite new and was exhibited by its raiser, but I can only place it in the list of second-rate flowers; the petals are well formed, and the flower full and nicely rounded, but the white is not pure, and lacking this no flower can be placed in the highest position. John Bayley (Dodwell), Mr. Battersby (Gibbons), and James Cheetham (Chadwick) all deserve honourable mention.

Rose Flakes constitute what may fitly be termed the ladies' class, and although it contains some most beautiful flowers some of the new varieties will certainly surpass the old sorts. At the head of the list must be placed the flower that gained the premium as the best Carnation in the Exhibition—Sybil (Holmes). It was shown by Mr. Turner, and well deserved the honours it received; its beautiful shell-like petals regularly marked with cherry rose on a pure white ground seem to leave nothing to be desired. Mrs. Dodwell (Lord) was shown in Mr. Dodwell's stand; the petals are of the finest shape, and the flower is regularly marked with bright rose—a first-class flower not yet in commerce. Of older flowers James Merryweather (Wood),

John Keet (Whitehead), Mary Ann (Fletcher), Flora's Garland (Brooks), and Lovely Ann (Ely), were the best.

Picotees were remarkably well shown. In the class for red-edged flowers the Picotee that gained the premium as being the best flower in the Exhibition was found in my stand of twenty-four—viz., John Smith (Bowers). It is a heavy red, the edge broad on a pure white ground without bars; when better known this flower will be much sought after. Princess of Wales (Fellowes) is a very fine heavy red, and is often equal to John Smith. J. B. Bryant (Ingram) and Leonora (Fellowes) made the four best heavy reds in the Exhibition. Light reds are a weak class, and in the single blooms only one flower was staged, a very fine specimen, however, from the collection of the Hon. Secretary—Thomas William. Although the flower was small the petals were well formed, ground colour pure white, and the edge without any feathering—a perfect wire. Mrs. Bowers (Bowers) was well shown in my stands. The ground colour is not sufficiently white, else it would be a very superior flower; the petals are large, beautifully formed, and the edge well defined.

In purple edges there were many flowers exhibited of the most faultless character. I am inclined to place Ann Lord (Lord) at the head of the list. The flowers shown were of the most perfect character—the edge a light wire; petals without spot or bar, and white, clear, and lustrous. This is a new flower sent out in 1874. Alice (Lord) is also very fine and will yet maintain a high position; similar in its style to the other. Zerlina (Lord), a beautiful heavy purple, quite distinct; the edge is not so broad as in Norfolk Beauty, Alliance, and others of that type, but I fancy it will hold a high position for many years. Minnie, another of Mr. Lord's flowers, is at present very fine at Loxford, and with it may be named Prima Donna and Sylvia, two of Mr. Ben Simonite's flowers, which will take a long time to surpass in light edges. Of older flowers in this class that were well shown may be named Mary (Simonite), Mrs. Little (Hooper), Mrs. May (Turner), Nymph (Lord), Picco (Jackson), Mrs. Summers (Simonite), and Cynthia (Turner).

We now come to the last and most delicately beautiful class, and many flowers were shown of the highest merit. There was one new flower to which a first-class certificate was awarded, named Lady Louisa; it has a very bright medium rosy red edge much in the way of Fanny Helen (Niven), but is altogether a better flower than that; the white is very pure indeed. It was exhibited by Mr. Turner, but Dr. Abercrombie of Cheltenham, who also exhibited a flower of it, is the raiser. Dr. Abercrombie exhibited several fine seedlings, amongst them No. 170, a light rose edge with a most beautiful clear white petal, in the way of Mrs. Allcroft. 186, heavy rose, of the Edith Dombain type, has the material to make a first-class flower. Older sorts shown in superb condition were Mrs. Allcroft (Turner), Ethel (Fellowes), Miss Lee (Lord), Juliana (Turner), and Miss Wood (Wood). Mr. Turner's new Glove Carnation Mrs. Matthews is a most valuable acquisition. I do not know another flower of such properties in cultivation; it is pure white, deliciously scented, and of the most vigorous growth. It received a first-class certificate.—J. DOUGLAS.

PORTRAITS OF PLANTS, FLOWERS, AND FRUITS

MESEM-BRYANTHEMUM SUTHERLANDII. *Nat. ord.*, Ficoideæ. *Linn.*, Icosandria Di-Pentagynia.—Flowers pink. "Mesembryanthemum Sutherlandii was sent to the Royal Gardens by Dr. Sutherland, Surveyor-General of the colony of Natal, in 1870, and has flowered annually in the summer months since 1872."—(*Bot. Mag.*, t. 6299.)

SALVIA SCHIMPERI. *Nat. ord.*, Labiata. *Linn.*, Diandria Monogynia.—"The subject of the present plate is a robust Sage, suited for the herbaceous ground, belonging to an Oriental group of the genus, and closely allied to the fine *S. asperata* of Kashmir. It was discovered by Schimper in the mountains near Axum, in Abyssinia, at an elevation of 7000 to 8000 feet above the sea, flowering in October, and was introduced by Mr. Bull, who sent the specimen here figured to Kew in July, 1875."—(*Ibid.*, t. 6300.)

ALOË CHINENSIS. *Nat. ord.*, Liliacæ. *Linn.*, Hexandria Monogynia.—"Our present plant is clearly quite distinct specifically from *A. barbadensis*. The leaves are never more than half the length of those of that species, and are spotted more or less copiously both on back and face after the fashion of *A. abyssinica*: the raceme is very much laxer, and the stamens are very much shorter. We have had it for a long time in the Kew collection, and have received it from other gardens, but never, so far as I know, with any definite information as to its native country. The drawing was made from a plant that flowered at Kew this spring. The flowers have a strong and decidedly unpleasant scent. Its affinity is with *A. barbadensis*, *abyssinica*, and *consobrina*."—(*Ibid.*, t. 6301.)

HÆLOPAPPUS SPINULOSUS. *Nat. ord.*, Compositæ. *Linn.*,

Syngenesia superflua.—"A widely distributed native of the prairies bordering the Rocky Mountains, from the boundary of the British possessions as far south as New Mexico, apparently common about the source of the Saskatchewan, Platte, and Colorado rivers. It forms a low corymbosely branched bush, 1 or 2 feet high, with innumerable branches from the root, clothed with small leaves, and bearing masses of flower-heads. One specimen from Mr. Veitch's garden, about 10 inches in diameter, bears nearly a hundred golden heads an inch in diameter, and I cannot doubt but that they will prove a most ornamental hardy garden plant when fully established, preferring, no doubt, a rather dry soil and climate, and flowering, like many other Compositæ, late in the year. The specimen figured was raised by Messrs. Veitch, who introduced it. It flowered with them in August, 1874."—(*Ibid.*, t. 6302.)

LYCASTE LINGUELLA. *Nat. ord.*, Orchidacæ. *Linn.*, Gynandria Monandria.—"Lycaste Linguella is, according to Reichenbach, supposed to be a native of Peru. It was imported by Messrs. Veitch, from whom it was received by the Royal Gardens, where it flowered in January, 1872. It was described in 1871 by Reichenbach, who states that it has a close affinity with *L. ciliata* and *L. lasipes*."—(*Ibid.*, t. 6303.)

TULIPA PULCHELLA. *Nat. ord.*, Liliacæ. *Linn.*, Hexandria Monogynia.—"It is a native of the alpine region of the Cilician Taurus, where it was discovered by Kotschy in 1836, and of course is perfectly hardy. It has only very lately been introduced into cultivation in this country. For the specimens figured we are indebted to the Rev. H. Harpur-Crewe, who flowered it at Drayton Beauchamp in the spring of this present year, and exhibited it at one of the meetings of the Scientific Committee of the Royal Horticultural Society."—(*Ibid.*, t. 6304.)

NEGLECTED ROSES.

THE OLD MONTHLY CHINA ROSE.—Very sorry am I to find that Messrs. Veitch and Messrs. Wood are the only nurserymen who still find space for this old favourite in their Rose catalogue, and I congratulate them upon their courage in retaining a good thing after it has ceased to be fashionable. Exhibition flowers have driven it not simply into the background, but quite out of many gardens; and yet what other sort, even among China Roses, is at all equal to the "old Monthly" in that most valuable property an abundant and continuous production of flowers? Even when the full charms of "Teas," "Noisettes," and "Perpetuals" are before us, the eye wanders involuntarily to the large bushes of the Rose—one cloud of blossom, most charming to the lover of what is really beautiful in nature, but just so many "horrors" to the rosarian who sees no beauty in any flower that is not "large, full, and of fine form;" and in autumn, when most other flowers have passed away and the exhibition boxes are put by till another season of National and Palace contests comes round again, there is still the "old Monthly" as fresh and gay and certainly more conspicuous than ever, imparting an air of brightness, life, and animation that is most pleasing at that season of dullness and decay.

Let it not be thought that I am at all insensible to the high merit of our best exhibition Roses; but, while yielding to them the praise and admiration of which they are so worthy, I hold that they should not be planted to the exclusion of those sorts which, however deficient in the excellencies of prize flowers, possess attractions of no mean order as simple garden flowers.

To have the "old Monthly" in full perfection the pruning knife should never come near it except to restrict its growth within due bounds. We do not look for fine flowers, but rather for a mass of them, which is precisely what we have when it is left to grow into a regular thicket. I have never tried a hedge of it, but I have no doubt it would form an admirable one in a short space of time, that might be kept in good order by clipping in winter to a precise formal outline, the stiffness of which would disappear in the new growth of spring.

BELLE DE BORDEAUX.—Who has not tried to grow this Rose and has not thrown it away in disgust? Glad enough am I to say I have tried, and, after failing to obtain a single good bloom for four years, am this year well rewarded with dozens of really magnificent blooms, every bud expanding into a perfect flower—large, full, and of fine form; the abundant broad recurved shell-like petals being of a rosy pink colour softening to a more delicate tint at the edges, and the under sides of a deep pink hue. The flowers attain an average size of 4 inches in diameter, and the foliage is also very fine, some of the leaves being 5 inches long by 3 broad, so that in both foliage

and flower it has merits which are infinitely superior to those of most other Tea-scented Roses.

I cannot give its history, but I believe it is not at all what we should term an old Rose, and yet when I turn to the catalogues I can only find it in an old one of Mr. W. Paul's, bearing the date of 1871-2. All of them appear to have found it an incorrigible bud-bound rogue—Turner, Veitch, G. Paul, Mitchell, Wood, Rivers, Lane, Standish, Fraser, Henderson, Smith of Worcester; in vain do I turn to any of them. All have turned their backs upon it. Mr. Charles Wood, who grows Roses by the acre and thousands of Tea Roses in pots, when he saw it the other day exclaimed, "Why! I had no idea it was so fine a Rose; we have discarded it as worthless." And, as few nurserymen grow Roses on such an extensive scale as Messrs. Wood, this observation affords conclusive proof that everybody else has also discarded it. I would therefore ask whether there has not been a little undue haste in so doing.

Why have I at length induced its flowers to expand as freely as a Cabbage Rose? Is it because the growth has only been pruned very slightly, precisely as one treats Cloth of Gold? Is it owing to the great vigour of the tree, which is now 10 feet high trained to a wall facing eastwards? Or is it owing to some peculiarity of the present season? Pray tell me, rosarians; and if you have an odd corner or a few square feet of wall space to spare, just give it to a plant of Belle de Bordeaux, and some day you will have a rich treat, and if that treat only occurs in every fifth year it will be well worth waiting for. Moreover, the foliage is so handsome and so superior to that of most other Roses that one might well afford some space even for that alone.—EDWARD LUCKHURST.

IN FLORA'S DOMAIN.

THERE are fashions in the cultivation of plants and flowers as in everything else, and it is often unfortunate that, when a change takes place, what is good of the old style is not retained and blended with the new. My thoughts were turned to this subject in the autumn of last year by seeing a very fine specimen of Magnolia, in full bloom, trained up a house in the Uxbridge road, opposite Holland Park, Bayswater. For some years after the introduction of the Magnolia it was without doubt very popular, and evidently met with due appreciation, for in most suburban gardens of a certain age we are nearly sure to find at least one fine specimen of this handsome evergreen, while the modern villa garden containing such a plant would be a remarkable exception. Indeed so little is the Magnolia known to the general public that last autumn, when the tree before mentioned was in bloom, I was repeatedly asked what the name of the plant was. Fashion after certain intervals, like history, repeats itself. We look forward to the time when the Magnolia shall again flourish in unlimited numbers on suburban house fronts and villa garden walls.

Between two and three hundred years ago, about the time of the Charleses, more particularly during the reign of Charles II. it was evidently a very prevalent fashion to plant Mulberry trees. Many living evidences of this fact exist in and around the metropolis, notably a magnificent tree in Lambeth, which tradition says was planted by the merry monarch's own hands and which has borne the burden of nigh upon three hundred years right royally, giving each summer a most umbrageous shade, and a wealth of fruit not to be equalled by younger members of the same family, in situations which might be supposed to be far more congenial to their healthy development. In what domain or in whose grounds the tree was originally planted history sayeth not; but many changes must have passed around since the time of the Cavaliers, for the tree stands in a strip of garden ground surrounded by houses, and its goodly proportions were some two years ago beginning to fall a prey to the mischievous propensities of many juveniles over whose miniature back gardens it threw its wide-spreading boughs. This noble old tree flourishes on the south side of the Thames in a now densely populated part of Lambeth. Beyond the Mulberry tree already cited many such magnificent trees are to be found in London, but they are all without exception fine old trees. Gardeners of the present generation have forgotten the Mulberry tree with the Magnolia. Effort to be gained by gorgeous contrasts of colour as displayed in bedding-out is the order of the day, not permanent interest in the garden engendered by the growth of perennial plants and trees, offsprings of our care and objects of our tender solicitude and our hopes year by year.

A certain phase of gardening, much in vogue some years ago,

was the growth of semi-hardy evergreens in tubs: a relic may be seen in the fine specimens of Orange trees placed in the gardens of Kensington Palace every summer. At the present time when the exigencies of space and the wants of a rapidly increasing population are compelling us to build towns on a uniform plan of straight fronts and backs, with no gardens, or rather only square air-spaces dignified by that name, with forecourts or areas of damp-proof uncompromising concrete which cannot of course by any possible means be made into a garden, it would be an excellent thing were householders to turn their attention to the cultivation of evergreens, flowering shrubs not necessarily evergreen, and creepers, in tubs and pots.

Among the modern features of town gardening the very general cultivation of the Virginian Creeper is much to be commended; but unfortunately a run has been made upon this plant to the almost total exclusion of other plants quite as suitable and handsomer, in this respect that they are as remarkable for beauty of bloom as for gracefulness of growth.

The Passion-Flower is not exacting in its requirements, and there is no valid reason against its flourishing on the same house front and festooning the same balcony as its American rival. It is not only of a free graceful habit, but it puts forth its particularly conspicuous flowers in positive profusion; and in autumn, when vegetation all around is subsiding into its winter sleep, the Passion-Flower is gay with numbers of bright golden fruits. Then also there is the unique Wistaria, with its graceful racemes of pale lavender blooms and its elegant foliage, which unfolds of an exquisite delicate brown and gradually becomes green. Ivy needs no comment. Those who appreciate its dense foliage and rapid growth will be sure to grow it, while some persons cannot endure the plant from an objection to the strong smell of the leaves when bruised, or its almost inseparable connection with scenes of ruin and decay, as exemplified by the late Charles Dickens's ever-popular poem "The Ivy Green." Although less rapid and rampant in growth than the plants already mentioned, the Japanese Honeysuckle with its small variegated foliage is invaluable for training around windows and along balconies. We might enumerate many other suitable subjects, but for the present let the foregoing suffice as a hint at what may be done even in towns by those who will observe and think for themselves.—T. S. J.

STAMPING OUT INJURIOUS INSECTS.

MY position with regard to the proposal brought forward by Mr. Andrew Murray for the extirpation of injurious insects is rather a neutral one, and there is much that might be stated which would give his theories a somewhat different aspect. Like the old lady, who when charged with stealing a saucepan proved conclusively to the jury that she could not have stolen the article if she would, and then appended the statement that she would not have thought it worth taking if she could have got it, I am not sure that such a thing as stamping out a species belonging to the fauna of a country, and of general distribution, could be done, nor that a very positive benefit would result if it were feasible. A strictly local insect may be snuffed out, as witness the disappearance of the Large Copper Butterfly, so also might a newly arrived visitor which has not succeeded in establishing itself. But the destruction of one pest may be followed by a large accession of numbers in the case of another pest, and arresting the increase of insect enemies has now and then apparently favoured the growth of fungoid or other parasites belonging to the vegetable kingdom. Nor are we always able to answer the question conclusively as to what is or what is not an insect gardeners should view as a foe, for our opinions undergo a change as our knowledge of entomology increases. For instance, there are certain flies of the Dipterous order which frequent flowers, and which had some years ago an evil repute because it was supposed they disfigured the blossoms by biting them. This they may occasionally do; but then we now find that they prey upon smaller species, which, breeding in the leaves or roots of plants, also resort to flowers, but which are kept in check by their particular foes. Other flies, again, long esteemed useless, are of much service in horticulture by their activity in the work of pollen-distribution. The excellent remarks of "A. N. G." in a recent number are deserving of general attention. Prevention is far better than remedial measures, and in the instance of the great bulk of moderately sized plants there is little doubt they are only insect-infested when they have been neglected or are in an unhealthy condition. One unavoidable evil

when we are attempting to eradicate insects while they are in full play is this, that with them we also destroy their natural enemies. Thus I have recently noted how numerous were the ladybirds and Syrphi that fell victims during the removal of aphides from plants. This could not be helped; but if we pushed our warfare against any species to the stamping-out point we might discover at last that we had stamped out the wrong insect.—J. R. S. C.

DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

KITCHEN GARDEN.

We were confident that this year our third sowing of Peas would be a great success, as much pains had been taken in the preparation of the ground. It had not been cropped for some time previously, and was in good condition at the time of sowing, but

"The best laid schemes of mice and men
Gae aft aglee,
And leave us nought but grief and shame
For promised joy."

In fact, we have been ashamed of them, until on a visit to Chiswick last week we found the Peas under the care of Mr. Barron in much the same condition, and another first-class gardener said that his crop was in the same unsatisfactory state. Part of the crop was watered, and those rows are even worse than the others. It is not easy to say what is the cause of such a failure, as we have done pretty well with Peas when the weather has been quite as dry in other years. We were so disheartened with our failure that we did not think it worth while to sow for a later crop. What an advantage the Scotch gardeners have over us in this respect. If they are a little later before they gather in early summer, they can continue gathering until the frosts cut down the haulm in October.

There have now been genial showers, which have well moistened the ground and prevented the Potato haulm from dying off prematurely, as it would otherwise have done, as the ground was quite dusty dry. In fact, the growth of some of the later sorts had been checked to that extent that the roots are what is called "growing out," or making a second growth from the tubers which were first formed. The most promising variety of recent introduction is "Schoolmaster." We expect that it will form a valuable succession to the Early Shaws, a variety well known in the London district as the best market round variety. It will come in between the Shaws and Dalmahoy Regents, and promises to be a better cropper than either.

We have been working the Dutch hoe in amongst all growing crops, especially Coleworts, Brussels Sprouts, Savoys, &c. It is no use expecting such crops to give satisfaction if the ground around the plants is not kept loose by frequent hoeing. We would also urge the necessity of great care being taken in the transplanting of all such plants, especially in dry weather. The small fibrous roots are the life of the plants, and how often do we see persons pull the plants out of the seed beds without any care as to whether the roots are wrenched off in the effort or not. Such treatment is most objectionable. To do the plants justice they ought to be pricked-out in beds a few inches apart when the first rough leaf is formed, and the plants should be put out before they are too large, first loosening them with a fork, and instead of planting with a dibber the work may be performed with a small planting trowel, and see that the plants are made firm about the roots, but not to be choked at the neck, as is not unfrequently done when they are planted carelessly with a dibber. As the ground is cleared of summer vegetables we prepare it by digging or trenching for the winter crops.

VINERIES.

At this season the work in this department is reduced to its minimum; but no Vines ought to be neglected altogether. We have already alluded to the importance of cleansing the leaves of red spider; where the fruit has all been gathered the drenchings with the garden engine must be repeated until the pest is destroyed. Thrips do not attack the leaves so frequently as red spider, but if they do so in considerable force the best plan is to close the house and fumigate strongly with tobacco smoke on three successive nights at intervals of three days. We were once very much annoyed with thrips attacking our Vines in the early Muscat house, and were two years in quite eradicating them. When the loose bark was removed from the canes in midwinter scores of healthy full-grown insects were found securely nestled under the bark. Of course this was all removed as much as possible, and the canes were well washed with the mixture we recommend at that season, of which the principal part is strong soft-soapy water and flowers of sulphur. A few appeared the next season, but with their appearance the tobacco smoke came into requisition, and since that time no thrips have nestled on our Vine leaves in summer or under the bark in winter.

It is highly important that Vines in pots intended to be forced

early should be in a place where the buds can be well plumped up while the leaves are yet green, and the strongest canes require the greatest amount of attention in this respect. When the wood is quite brown and hard throughout the length of the cane intended to be forced, and the eyes are prominent, it is a good plan to place the pots out of doors against a wall facing south or west; but do not allow the soil in the pots to become overdry. We never give any manure water, nor do we surface-dress the pots until the Vines have started into growth next season.

CUCUMBERS AND MELONS.

In the remarks on these in the number for July 19th it was stated that artificial heat would not be required for the next six months; it ought to have been six weeks, and even this applies to the south of England only, as the reports from the north are that the weather is very cold indeed, and it is certain that in our treatment of such plants with ripening fruit we must adapt our treatment to surrounding circumstances. Young gardeners especially will do well to take notice of the excellent article in last week's number on Melons. Our own experience has been similar to that of "J. W." We have gained first prizes with green and scarlet-flesh Melons in London, and have, with other fruits that it was necessary to keep longer, been left out without any prizes. The difficulty with us, as we grow but few plants, is to obtain fruit of the proper age on the day of exhibition or to present it on the table when it is most wanted. We are not using any artificial heat, and Cucumbers are producing well and the fruit is of most excellent quality. Melons ripening should have plenty of air admitted, and the house to be kept moderately dry.

PLANT STOVE AND ORCHID HOUSE.

With the advent of August the days have very perceptibly diminished in length, and cold nights are expected. The influence of the sun's rays have not such a burning effect on the plants, and it is well not to allow the blinds to be down, except to prevent the plants from receiving injury; indeed shading such plants as *Ixoras*, *Stephanotis*, and others of this character is very injurious to them after this date. We seldom visit any gardens where the plant stoves are quite free from mealy bug, and our own experience leads us to believe that at this season the pest spreads very rapidly indeed. No opportunity ought to be lost in order to destroy it. We generally attack it with soapy water and a sponge, removing the insects, which are easily killed, and then washing off all the woolly substance and filth that may have accumulated.

Climbing plants, whether permanently trained to the rafters or grown in that way to be afterwards trained to a trellis to form specimens, should have the growths regulated, and these should not be allowed to twine round the wires, else it is very difficult to remove them afterwards without considerably injuring them. When climbers are planted out in borders they generally grow too much wood and do not flower freely. The best way to restrain exuberant growth is to withhold water, even to the point of causing the leaves to flag; this will probably aid in the formation of flower buds, but the drying-up must not be carried to the point of causing the plants to shed their leaves. The showy *Allamanda Schottii* not unfrequently runs more to growth than flower. A drier atmosphere and a lower night temperature is desirable for those plants that are entering upon their season of rest for early flowering next year.

Orchids require very similar treatment as regards temperature and atmospheric moisture to stove plants. *Dendrobiums* and *Cattleyas* must have all the light they will endure without injury from the sun. *Cattleyas* will do without shade altogether except in days when the sun is scorching hot. Those who have a house devoted entirely to this class of plants will be able to give them the treatment best adapted to their wants, but in our little house we have *Anguloas*, *Odontoglossum citrosimum*, *O. phalaenopsis*, *O. hastilabium*, *O. pulchellum*, and others that succeed best in the *Cattleya* house, but many of them will not bear so much sun as *Cattleyas*. If any plants require repotting it ought to be done at once, else the plants will not become established before the dull dark days of autumn and winter. Some plants which were potted a few weeks ago are making strong healthy roots. The cool house requires abundant supplies of atmospheric moisture; but this must not be carried to excess, as we find the young growths will damp off under a saturated state of the atmosphere, especially when the shadings are kept on too much. *Masdevallias* and *Odontoglossum crispum* which were potted early in July are also making very satisfactory progress in the formation of new roots. All plants of this character that require to be kept very moist at the roots require to be repotted oftener than *Cattleyas* and *Laelias*, which do best if the material in which the roots are kept rather dry. We mostly pot our *Cattleyas* once in two years, but some of the best growers will allow plants to remain in the same compost for at least seven years. They say that as long as the plant continues to make strong flowering growths it is better not to pot it. It is quite certain that if suitable compost cannot be obtained it is much better to let well alone. If any white scale

should appear on the pseudobulbs see that it is at once washed off, as it speedily causes the leaves to become yellow and seriously interferes with the health of the plants. Admit as much air as possible, but do not allow the winds to blow directly on the plants. A canvas screen over the ventilators is a wise precaution.—J. DOUGLAS.

TRADE CATALOGUES RECEIVED.

Vilmorin-Andrieux & Cie, 4, Quai de la Mégisserie, à Paris.—*Catalogues of Flower Seeds, Bulbs, and Strawberries.*

TO CORRESPONDENTS.

* * All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

EXHIBITING ASTERS AND GLADIOLI (*Giles*).—The best way to exhibit Asters is in a stand, with a neat white card placed under each flower. Gladioli should be exhibited in stands. Those made by Chapman of Gloucester are the best.

CULINARY VEGETABLE (*G. C.*).—The Cucumber is certainly a culinary vegetable, for it is cooked in various ways, and consequently is a kitchen vegetable.

MELON PLANT FAILING (*T. R. C.*).—The plant seems to have ceased producing fibrous roots. The cause we cannot tell. The watering with cold water during a hot day may have been the cause.

AMERICAN PERIODICAL (*A. S. J.*).—Write to Messrs. Sampson Low & Co., Bookellers, Fleet Street.

WANT OF BLUE IN GARDENS.—"A Lady Gardener" observes that we want more blue in our flower gardens. She saw this spring the Red Campan of our hedges made to grow as a compact garden flower, and she wants to know if the same could not be done with the blue-flowered *Cichorium Intybus* (wild Chicory or Succory).

KLEINIA REPENS (*J. B.*).—Send your address to Mr. C. Chisholm, 300, King's Road, Chelsea.

CINERARIAS (*Amateur*).—Sow the seed now on light soil previously moistened, and cover very slightly with very fine soil; place in a frame or shady position in the garden, covering the seed pot or pan with a square of glass, and place the pan in a saucer containing a little water. The soil must never become dry, and the seedlings will soon appear and be ready for pricking-off or potting. As slugs ate your first lot of seedlings you must take special care of the second. Sometimes when a pan is placed in water the soil becomes too wet, but your plants will be equally secure against slugs if you invert a flower pot in a deep saucer of water and place the seed pan on the inverted pot.

ROSES (*George*).—We cannot name varieties. (*Turkey*).—We cannot tell the name of the grubs unless we saw live specimens. Dusting with lime might destroy them, and syringing the trees the next day would remove the whitewash.

FUNGUS ON LAWN (*A Very Old Subscriber*).—Sprinkle common salt over the places where the fungus grows. We should remove the fungi before using the mowing machine.

ROSES FOR A TOWN GARDEN (*Stephen*).—Yes, you may use charcoal advantageously, but remember plenty of rich manure is the mainspring of success. In your somewhat unfavourable position for Rose culture it will be best to confine yourself to varieties of robust growth. Here are a dozen such—Gloire de Dijon, John Hopper, Paul Neron, Boule de Neige, Madame C. Joigneaux, Baronne de Rothschild, Charles Lawson, Paul Verdier, Anna Alexieff, Gabriel de Peyronny, Countess of Oxford, Charles Lefebvre, and Reine du Midi, to which add the old Cabbage Rose, very pretty and very sweet-scented. November is the best month for planting. Consult your own taste as to what form of trees you plant, dwarfs and half-standards being quite upon a par as regards freedom of growth and production of bloom.

ROSE LEAVES INSECT-EATEN (*J. E. Coleby*).—They are attacked by the grubs of a small moth called *Microsetia centifoliella*.

WIREWORM INFESTING CORN CROPS AND POTATOES (*Sigma*).—Gas lime, of which you have been advised, is a capital application. It may be applied in March at the rate of twenty bushels per acre, or in autumn at the rate of thirty bushels. If applied in autumn it may be ploughed under, but if in spring it should remain on the surface until after rain, the ground being then worked prior to sowing or planting. Grain crops may have a dressing of nitrate of soda when the crop is well up, at the rate of 1 cwt. per acre, or twenty bushels of salt, but the nitrate of soda is the most powerful agent in the destruction of vermin.

WATER LILY PLANTING (*H. B.*).—The best time to plant is in spring from March until May, so that the plants may become well established before winter. The roots should be in not less than 1 foot depth of water, and not exceeding 3 feet. If the bottom be soft a stone or half brick may be secured to the root-stem with wire, and the plants be dropped or thrown into the water where required; but should the bottom be hard the plants should be planted in strong loam in shallow wicker baskets. The plants will be established before or by the time the basket decays. They must be secured to the bottom by some means to prevent them floating. There are a number

of kinds of Water Lilies—viz., *Nymphaea alba*, common white Water Lily; *N. odorata*, very sweet, and a variety of it, *N. odorata minor*; *N. candidissima* is noted for its pearly whiteness, *N. pygmaea* for its smallness of growth, and *N. tuberosa* for its large root-stems. The yellow Water Lily is *Nuphar lutea*, another good kind being *Nuphar advena*, and a very dwarf kind, *Nuphar pumila minima*. One of the sweetest of aquatics is *Aponogeton distachyon*, which with its small form minor is also very suitable for growing in a pan in the greenhouse.

MILDEW ON GOOSEBERRY BUSHES (*Idem*).—It is probably due to dryness of the soil, and the remedy will be a more liberal dressing of manure annually, or copious applications of water with liquid manure in dry weather. Syringe the trees with a solution of soft soap, 2 ozs. to the gallon of water.

GERANIUM LEAVES PERFORATED (*A. Boyle*).—The leaf is perforated by some insect, probably a weevil or beetle, which usually commit their depredations at night. We should place a white cloth on the ground and shake the plants over it after dark, when the pests may fall on to the cloth. We should also water the plants overhead with paraffin water just after dark, allowing a wineglassful of the oil to three gallons of water, stirring well up and letting it stand twenty-four hours, then skim off the oil rising to the surface, and then use the water, taking care to thoroughly clear it of the oil before use.

STRAWBERRIES FOR FORCING (*C. M.*).—The best varieties are Keens' Seedling, President, Sir Charles Napier, and Sir Joseph Paxton. It is not desirable to keep the plants very dry in the winter—just sufficient to keep the roots in a healthy growing condition. If the small rootlets suffer from overdryness the crop of fruit will be jeopardised.

PROPAGATING ROSES FROM CUTTINGS (*Flora*).—October is perhaps the best month for this, but they may be put in at any time when the wood is firm. The cuttings ought to be taken off at the base with what gardeners term a heel. If a quantity of cuttings have to be inserted we would place some suitable soil in the frame and then plant out the cuttings in it. Keep the lights close until they are rooted. When inserting the cuttings press the soil (which ought to be two parts loam, one leaf soil, and one of sand) firmly round the base of the cuttings. Some sand should be placed on the surface before inserting them.

VINES ATTACKED BY PHYLLOXERA VASTATRIX (*C. T. D.*).—There is no remedy for this disease, and no one ought to tamper with it. The wisest plan is to root the Vines out and burn them, removing the soil to a safe distance from any Vines. Not a single bit of root ought to remain in the ground.

SOWING CABBAGE SEED (*G. N. R.*).—The Fulham or Early Battersea, Nonpareil, and Atkins' Matchless are as good as any. A sowing should be made about the 21st of July for final planting-out early in September, many plants of which will be turning in between Michaelmas and Christmas and in early spring. The second and most general time of sowing, to raise plants for almost the whole year's supply, and of any kind, including the Red Dutch and its varieties, is from the 12th of August, and the seedlings may remain in the seed bed all the winter if not too thick, or any number may be finally planted in the open quarters from October to November, or pricked-out into nursery beds, banks, &c., so as to have a good stock of plants for final planting-out whenever favourable opportunities offer. The soil should be soaked with water twelve hours before the seed is sown, for after raking and forking it is thus rendered less liable to become hard and surface-bound. The seed should also be soaked twelve hours previously to sowing in dry weather. In hot dry weather the evening is always the best time to sow, not covering the seed more than a quarter of an inch; and the seed beds should be slightly shaded with boughs, straw, or any other article of a similar description, until the young plants are just appearing above the surface, when the covering must be removed. A slight sprinkling of water must then be applied and a top-dressing of charcoal dust, so that it may adhere to the young plants while moist, which will not only prevent the attacks of the fly but promote growth. When about 8 inches high thin the seedlings to 4 inches apart, and prick out those removed into beds prepared as for the seed bed, planting them 4 inches apart. We never make but two plantings in the year: one from the 21st of July sowing, which planting is made during the first fortnight of September, and the second planting is made in the spring, towards the end of February or beginning of March. Plant in rows from 1½ to 2½ feet asunder each way, the smaller earlier kinds being planted the closest.

SQUIRRELS (*A. O. W.*).—The gun is your only resource to preserve your nuts from squirrels.

SOOLY QUA CUCUMBER (*South Wales*).—We do not know of its being eaten raw, but we do know of its being boiled and eaten with rice, melted butter, &c.

FUCHSIA SUNRAY.—"B. C." wishes to know if this is "an intermediate variety or a self."

ROSES (*P. B. C.*).—The small pink Rose is Manetti. The white is very common and useful, but we never heard it named.

GRAPES CRACKING (*Clericus*).—The Chasselas Musqué and Madresfield Court are very liable to have their berries crack. Allow the Vine to have a full crop, keep the roots rather dry when the fruit is ripening, and, if the berries still crack, cut a notch in the branch below each bunch to reduce the supply of sap to it.

HOP PLANT DYING (*J. Huish*).—Examine the roots; something has probably destroyed them, as the other Hop plants are healthy.

AQUILEGIAS.—"J. B. J." asks, "Where can I get plants of the Aquilegias mentioned by your correspondent Mr. Addison? The *A. glandulosa* flowers very freely here, and is beautiful. The soil requires to be very rich."

SIX DIFFERENT KINDS OF FRUIT (*J. F.*).—Two varieties of Grapes ought not to be admitted in the class so restricted.

NAMES OF PLANTS (*J. A.*).—The Bog Pimpernel (*Anagallis tenella*) (*Somerset*).—1, *Geranium sanguineum*; 2, *G. sylvaticum*; 3, *Veronica spicata* (white-flowered variety); 4, *Santolina Chamæoparissus*; 5, *Hemerocallis fulva*; 6, *Lilium martagon*. (*A. H. S.*).—1, *Catasetum deltoideum* (?); 2, *Eulophia* sp. (*A. Novice*).—The shrub is commonly called Southernwood, *Asteris abrotanum*. The fleshy-leaved plant is *Sedum azoideum* variegatum. (*R. T.*).—The Fern is *Adiantum trapeziforme*. (*D. G. R.*).—1, *Oxalis* sp.; 2, *Yarrow* (*Achillea millefolium*); 3, *Centaury* (*Erethraea Centaureum*); 4, *Heracleum Sphenodyllum*; 5, *Cherophylhum temulum*; 6, *Tradescantia virginica*. (*F. T.*).—1, The Acer seems to us only *A. pseudo-Platanus*; 2, *Trifolium procumbens*; 3, *Lathyrus pratensis*. (*Helena*).—We cannot name florists' varieties. No. 1 has no fructification.

POULTRY, BEE, AND PIGEON CHRONICLE.

LABELS.

Worse than ever grows this grievance. It surpasses, if it is possible, the catalogue difficulty. The latter, however, we have, as far as we are concerned, simplified by never ordering a catalogue at all, as it seems to us needless expenditure to put several pence into a society's pocket for no derivable good whatever. The label trouble, however, is less easy to deal so summarily with, for if once fanciers exhibit—labels and their consequent difficulties have to follow. Labels fail to arrive at all—not in an isolated instance, as that may always occur with any show by some postal mistake or by the secretary's overlooking a name accidentally; but some half-dozen or so at one time fail to arrive. Again, when the birds ought to have been near the end of their destination the labels sometimes come, when they are quite useless for that show. Now, in such cases what has to be done? Provided a receipt has been previously forwarded, it is generally safe to send the birds on to the secretary's care; but these label mistakes seldom occur at exhibitions where receipts are forwarded, for those are too well worked; but when no receipt has been sent, and no labels come to hand, what should be done? How can the exhibitor know the entries have ever been received, and that accommodation has been provided for the exhibits? We know this same difficulty happened the other day to Mr. Darby. He had entered eight pens for Bath, and had sent the 40s. to pay for the entries. The latter never reached Mr. Goodwin, so he could not send the labels. Mr. Darby, however, had often before received his labels late, and so he imagined this to be another such case, and so he sent on his birds. On their arrival they had never been entered, and he had incurred labour, trouble, and expense for nothing. Now, had all secretaries a general rule that receipts were to be sent for all entries, and this was understood, then the non-arrival of labels should generally mean that the entries had never come to hand or not been accepted. There are, however, some societies which accept entries long after the advertised date of closing—take them, in fact, so near to the date of the show that it is impossible to get the labels sent away in time to reach their destination when they are required. These post entries, however, are not so much in vogue as they were, for we have heard of many lately who had their entries returned for being too late. We are extremely glad of it, for, apart from the label annoyance it frequently causes, the system is not fair to those who have entered in the due time.

Another objectionable practice we have to condemn among the label managers of exhibitions is the plan of writing the address upon them before they are forwarded to the exhibitors. It is odious for several reasons, especially because the postal address and the train address of many people are often quite different. We know, for instance, a village, the post town of which is Bath, and yet the inhabitants have no less than twenty or more stations which are much more convenient to them than their post town's. Again, some may want to send the birds on to another show, or to some friend who keeps them for them; or again, some exhibitors may have a town address where their place of business is, while they themselves live out in the country and keep their birds there, so if a label comes disfigured by being addressed, as we have often had them, it is difficult to write the desired address upon them plainly. We have had, too, one single label addressed and stamped with a halfpenny stamp, and then sent us by post without any envelope or wrapper. Can any plan be more stupid? It is a great chance that it gets lost in transit through the many hands it naturally would have to pass. Another most objectionable sort of label is a one-eyed one, where it is possible to affix by one end only. Plenty of cases are on record to tell how such a label has failed entirely in its object. We remember two or three summers ago sending a basket of birds to the Middleton Show; the label had but one eye, and was consequently fixed but in one place. On one side was the show address, while our own was written on the other side for the return of the basket at the close of the show. The basket got as far as Crewe, when the parcel clerk, looking into the van, saw the basket of birds and read the side of the label for the home journey. Out of the van he took them, and back went the birds to London. "How quickly they have come back this time," said our poultryman: very quickly, but they had never seen at all the smoky country of Middleton. And so we could tell of other instances, most of which could have been obviated by a properly-made label. Some societies, again, send labels as large as a cheese plate, others about as small as a crown piece; very likely neither of them with the county printed at all. Those committees surely must forget that there are scores of little stations in England which are used by exhibitors where the porters or booking clerks are of such simple education as to be perfectly ignorant of the locality of many towns. It would tire us to tell of instances where we have heard how

trains have been missed or birds misforwarded from want of proper knowledge on the part of the railway officials as to the county where the package had to go to. Once we remember we had long hoped for a certain cup at Fakenham. The label had no county on it, and the parcels clerk had no more idea than the fowls themselves where Fakenham was. The train was moving from the station, he afterwards told us, and he did not know what to do, so in a fit of despair he popped them into the train, labelled "via Reading." He could not have made a worse shot, and it is needless to say the coveted cup did not fall into our hands.

And so from all these little things we can collect into one idea what a label should be to be of general service. It should be made of stout linen of a medium size, with an eyelet hole at each end; it should be printed clearly with the name of the county, and it is of no advantage to see, as we frequently do, "To the Poultry Exhibition" printed in gigantic capitals, while the name of the town or village is in modest little letters underneath. Above all, the labels should be despatched at least four days before the show is to take place, and sooner if possible. They should be printed reverse ways, on the back and front, so that at the close of the show when the packer turns the double label over to send off the birds he may find that the printing always turns over in a way to be at once legible. We have a vast number of important shows coming on in the next three months, and we hope they will in their label arrangements set an example to the smaller exhibitions, that complaints of this particular kind may be less constant than they have previously been. We are sure this is not a trouble of all cry and no wool, for we have on our table before us some dozen letters of the past month alluding to the subject in some form.—W.

BRADFORD, TONG, AND DUDLEY HILL
POULTRY SHOW.

THE annual Show was held at Dudley Hill on the 28th inst. in the Cricket Grounds. The poultry were shown in the open field in Turner's pens, and unfortunately the day proved wet. Some of the classes were badly supported with entries, but the quality was good, *Game* being a fair section, and the awards correctly made. A class was provided for single hens, the first going to a grand Silver Polish, and second to Spanish. *Hamburghs*, for the few shown, were really good. *Game Bantams* very good. Piles first and Black Reds second.

In *Pigeons*, which mustered better than poultry, there were many well-known winners. The Carriers very good. First a young Black cock, which should have yielded to a grand Black hen from the same loft, but which was taken for a cock by the Judges. Tumblers.—First Black Bald Long-face, second Blue Short-face, the latter capital in head but foul on thigh. In Antwerps first was a capital Dun, second a better-headed Red, but not so good in colour. Owls (English) very good. In the Dragoons the winners were Blues; but we preferred Pen 3, a grand Yellow hen.

Rabbits (Lops) ten entries, among which were some very good animals. In the Variety class first was a Himalayan, second Silver-Grey, and third a Grey Dutch; but the best Silver in the class was Pen 13 (Burton).

POULTRY.—SPANISH.—1, J. Thresh. DORINGS.—1, H. Beldon. COCHIN-CHINA.—1, C. Seligman. 2, W. Mitchell. GAME.—Black-breasted or other Red. 1, W. Schofield. 2, H. C. & W. Mason. Duckwinged or other Grey or Blue. 1, H. C. & W. Mason. Black, Brassy-winged, or Pile.—1, H. C. & W. Mason. 2, R. Walker. Hen.—1, H. Beldon. 2, W. Kirth. *vhc.* J. Hoigson. HAMBURGHS.—Golden-spangled.—1, H. Beldon. 2, B. Rawnsley. Silver-spangled.—1, Fawcett & Anderson. 2, H. Beldon. Silver-pencilled.—1, B. Rawnsley. 2, H. Beldon. POLISH.—1, H. Beldon. 2, J. Rawnsley. BRAHMA FOOTRA.—1, H. Beldon. 2, W. Schofield. *vhc.* H. W. & H. King. BANTAMS.—Game.—1 and 2, W. F. Entwistle. Any other variety.—1, J. F. Crowther. 2, H. Beldon. ANY BREED.—Cock.—1, H. Beldon. 2, J. JUDGES.—Messrs. Cannan & Dixon.

BOSTON POULTRY SHOW.

THIS Exhibition, which we are informed was a very good one, was held on the 26th and 27th ult. in connection with the Show of the Lincolnshire Agricultural Society. The following awards were made by the Judges:—

POULTRY.—DORINGS.—1 and 4, J. Hornsby. 2, J. Walker. 3, B. Smith. GAME.—Red, or any other Dark colour.—1, C. Chaloner. 2, W. G. Waters. White Piles, or any other Light colour.—1, C. Chaloner. 2, W. G. Waters. COCHINS.—1, R. P. Perrow. 2, J. Walker. 3, Dr. E. Snell. BRAHMAS.—1, J. F. Smith. 2, J. Walker. 3, Dr. E. Snell. SPANISH.—1, R. Newitt. 2, E. Biggadike. HAMBURGHS.—Spangled.—1, J. Long. Pencilled.—1, C. W. Gibbs. 2 and 3, Dr. E. Snell. HOUDANS.—1, J. E. Pilgrim. 2, Rev. A. B. Shipworth. 3, Mrs.

Cross. CREVE-CŒURS.—1, C. W. Gibbs. 2, Robinson & Myers. POLANDS.—1, R. Newbitt. 2, J. Long. BANTAMS.—Red, or any other Dark colour.—1 and 3, R. Newbitt. 2, J. Atkinson. Any Light colour.—1, R. Newbitt. 2 and 3, W. Roe. ANY OTHER VARIETY.—1, J. Long. 2, Dr. E. Snell. 3, Mrs. Cross. SELLING CLASS.—Cock.—1, J. T. Codrington. 2, R. Newbitt. 3, C. W. Gibbs. 4, J. Long. Hens.—1, J. Hornsby. 2, W. Roe. 3, Mrs. Cross. 4, J. Long. GEESE.—1, Dr. E. Snell. 2, J. Walker. 3, B. Armitage, jun. Ducks.—Aylesbury.—1 and 3, J. Walker. 2, Dr. E. Snell. Rouen.—1 and 3, J. Walker. 2, W. Bygott, jun. Any other variety.—1 and 2, J. Walker. TURKEYS.—1, J. Walker. 2, Mrs. Grundy. GUINEA FOWLS.—1, Dr. E. Snell. MISCELLANEOUS SELLING CLASS.—1, R. Newbitt. 2, W. G. Waters. 3, W. Bygott, jun. 4, Dr. E. Snell. 5, J. Hornsby. PIGEONS.—CARRIERS.—1, H. Yardley. TUMBLERS.—1 and 2, H. Yardley. FANTAILS.—1 and 2, J. F. Leversidge. ANY OTHER VARIETY.—1, H. Yardley. 2, R. Foster.

WHITCHURCH SHOW OF POULTRY, &c.

THIS Exhibition was held in a covered tent in connection with the Salop Agricultural Society's Show. The entries were not large, but the quality in most classes was excellent. Mr. Dixon of Bradford and Mr. Lane of Birmingham awarded the prizes.

Dark Dorkings opened the catalogue. The cup went to a large pair shown by Mr. Walker; they were square-shaped good specimens. The cock in the second pen had a bad comb, while the third were but a fair pair. The next class, for Silvers and Whites, had no entries, and the former one had only five pens. Brown and Partridge Cochins followed, where again there were only five pens, and Messrs. Percival's and Wood's being empty Mr. Tudman walked his three pens in for the three prizes. Of Buffs there were six pens, and for the time of the year the quality was good; pen 12 (Darby) were a little faded in colour, or else as good as any pen. In the next class Blacks and Whites met together. There were three pens of the latter colour and one of the former. The cocks here were in better plumage than the hens, the first-prize bird being in grand feather, and was the same bird we fancy which we saw at Banbury. In Dark Brahmas, of which there were eight pens, the cup pen was good and very silvery in colour; the second pen, too, belonging to the same exhibitor, were of much merit, as too was the highly commended pen (25) of Mr. Aspden. In Light Brahmas a pen of chickens came in second. There were half a dozen pens of this colour. Game made fine classes, as is usually the case in this district; not many pens, however, save the winners were in good condition. The cup pen of Black Reds were splendid, being really good all round. In Brown Reds the winners were well chosen; and in the next class a fine pen of Piles won easily, second and third going to good Duckwings. Spanish made only six entries, five of which were noticed. The cup pen was good, the winning hen being excellent. In Spangled Hamburgs Gold, Silver, and Gold won in this order. All the three pens were in good trim. Pens 76 (Rawnsley) and 77 (Beldon) were two excellent pens of Golds. In Pencils Mr. Beldon won the cup with a smart pen, both birds in good feather and condition. French had nine entries, where the quality was good. Crêves won first, and good forward Houdan chickens second, Crêves being third again. Game Bantams produced fourteen pens, of which Messrs. Fraser's, Cock's, and Adams's were without occupants. The cup went to capital Piles five months old as the catalogue terms them; second were Duckwings; and third pretty Black Red chickens. In the next class good Blacks were first and third, while a charming pen of Silver-laced came in between them. In the Variety class, which contained ten entries, Silver Polands of grand quality came in first, very lustrous Black Hamburgs being second, and Scotch Greys third. 124 (Darby) were good Black Polands; the cockerel had a large crest, but not a very prettily-shaped one. In the chicken class, which comprised twenty-two pens, Dark Brahmas were first, Brown Red Game second, and Houdans third. Turkeys had four pens. The winners were very large and in good condition; second were a large pair also, and third went to good Cambridge. Geese made five pens; the winners were large birds, all of fine quality. Aylesbury Ducks made only four pens, the winners large and clear in bills; second not quite so heavy in appearance, but very good. The Variety Duck class was truly excellent. Of the other nine pens seven won cards from the Judge.

The Pigeons were of fair quality in most classes. The Fantails especially good; a sweetly pretty pair of young Whites were first, and another good pen of the same colour were second. Nuns only brought three pens and Barbs the same number, and Pouters again only a trio, and we are afraid many of these classes will bring much loss on the Committee. In Owls the winners were very pretty and good; the second Blues we much admired. In the Variety class fine Black Trumpeters were first, very fair Red Turbits second. Of Dragons there were eleven pens, Mr. Wood's taking both honours with excellent Blues and Yellows. Antwerps, too, made a large class, and here Duns of fine quality came in first.

THE SILVER-GREY RABBIT.

THE Silver-Grey, although one of the smaller breeds, is considerably larger than the Dutch or Himalayan varieties. Seven and 8 lbs. are the usual weights of good healthy full-grown specimens, anything above 8 lbs. being an exception to the rule. The appearance is neat and pretty, rather stumpy and well-conditioned, with an arched back. The legs are well set and strong, the head rather small and inclined to be sharp at the nose. The eyes are usually of a dark colour, and very brilliant in appearance. The ears are short and erect without any tendency to lopping, although they occasionally fall a little outwards. The best appearance is that of the common hutch Rabbit, with the ears nearly parallel and falling rather forward than otherwise. The whole form is neat, and seldom fails to attract admiration.

The variety may, for the purpose of description, be advantageously divided into two parts—the dark shade and the light. Opinions differ as to the more valuable, public esteem having veered from one to the other and back again until now the shade most admired is a mixture between the two. To such an extent has the shade question been worked that prizes are to some extent monopolised by certain strains, although as some judges prefer one shade and some another, while others prefer a mixture of the two, the monopoly is not likely to do much harm or to check their culture. The shade is decidedly peculiar, and the appearance is often strange before a close inspection has shown how things are; the fact is, the animal has two distinct qualities of hair—a light and a dark. The latter is almost black and rather short, hence when born the animal is black. The other hairs are of a silvery shade—a sort of bluish grey; these are much longer, and do not make their appearance until the Rabbit is a month or two old. The great points to be aimed at are first a good shade, and secondly uniformity of shade. The former may generally be obtained by care and diligence, but the latter desideratum is not a goal easy of access. Fancy, that fickle and hard-to-be-pleased goddess, calls loudly for dark nose, ears, and toes in the Himalayan, and, like the man in the fable who blew hot and cold with the same breath, calls equally loudly for uniformity in these points with the remainder of the body in silver-grey. The head is generally a shade darker than the body, especially among the darker or Chinchilla variety. It does not detract at all from the animal's beauty, and, except in very close competition, does not tell much against it, provided of course that the comparison is not very obvious and that the shade is good. The nose often gives much trouble, there being two crimes of which it is occasionally guilty. In the first place it sometimes has a white spot upon it, and this is a heinous offence, not only to the fancier but also to the casual spectator, as it detracts considerably from the beauty. Then again it will sometimes refuse to "silver," as the fancy call it. The longer and lighter hairs do not make their appearance, and hence the short and black are only visible, and the nose retains its pristine blackness, and that which would make the heart of the Himalayan breeder dance for joy has a very contrary effect upon the keeper of Silver-Greys. The feet, too, sometimes err. It is rare that these members are too dark, but they not unfrequently present a scraggy grey appearance that is far from being proper. As to the colouring of the belly and under quarters, it is of course much lighter and often approaches pure white. There is a great variety of shading; the best of all, in our opinion, is the uniform medium shade, as preferable to the heavy or mealy, while of the two latter we prefer the former.

In order to obtain the desired strain very careful breeding is required, and as the strains generally breed pretty true if reasonable care is employed there need be little fear of success. The crossing of a heavy swell with a mealy doe will often produce the desired shade. Beware always of white noses, and if possible keep them from the breeding stock. There can be but little doubt that this is the result of a cross, however far back, and these remote crossings give much trouble to eradicate.

The Silver-Grey is very prolific. The litters will be as frequent as discretion calls for them, and the number of young may generally be relied upon to exceed half a dozen. The doe

is a most zealous and anxious mother, preparing her nest with forethought and skill, and tending her little black progeny with great attention. The young are born perfectly black, and remain so for some time, the period of "silvering," or the growth of the longer hairs, being dependant chiefly upon the atmosphere in which the animal is kept, a warm congenial temperature being calculated to hurry on the process, while a cold unfriendly climate will have the effect of retarding it.

The Silver-Grey is easily tamed and soon becomes accustomed to its feeder, resenting any change. It is described as being unusually docile; but while frankly giving it a name for being a tame pleasant animal, we can hardly go so far as to point out its docility as a speciality. They will not agree together when full grown, being decidedly pugilistic to one another. The doe will protect her young jealously, and will attack any intruder.

The skin of the Silver-Grey is its chief mercantile utility, being very useful for muffs and the like. The flesh is very good, and as the animal will attain a large size and put on flesh very readily it will do well as a pot animal. It is thus seen that Silver-Grey keeping is by no means an unprofitable investment.—G.E.T.

THE PRESENT BEE SEASON.

THE letter of "B. & W." at the end of May would have tempted me to ask you to insert a letter in your next issue, taking a different and more hopeful view of our prospects, had it not come from so high an authority on bee subjects. The state of affairs at the end of May this year was certainly better than 1876, which subsequently proved a splendid honey season, and I fondly hoped for a similar turn of affairs this year. This, indeed, we had as far as June was concerned, nearly every day from the 4th to the 20th yielding a large crop of honey. Then came the usual cessation, which has continued till the present time, and seems only too likely to continue unless we very soon have dry and very hot weather. The latter, I think, is the great desideratum for bee-keepers. This, I believe, explains why "B. & W.'s" hives, as well as everyone else's, seem to be almost empty of bees compared with what they appeared during the hot weather of June. Should the weather now become thoroughly hot for a week or two, I believe all bee-keepers who have not noticed the effect of sudden hot and fine weather would be surprised as well as delighted at the result; of this I feel certain, after carefully reading my notes of last season, when honey was gathered until the 8th or 9th of August. If cold and damp weather continues, however, the only possible success of this season remaining must come from the moors. My experience of 1875, with its splendid May and nothing afterwards, does not make me altogether anxious for early seasons. The earlier the season—i.e., the spell of hot weather, the sooner, as a rule, it is over, and the longer will the bees have to live on their stores.

As following-up the subject of Mr. Pettigrew's letter of the week before last, I will state the result of queen-raising in my unicombe hive last year and this. In 1876, on July 15th, I removed the queen with a few bees, placing them in a hive of brood from which I drove its own bees. Good results followed with both these hives. The new queen was hatched on the thirteenth day, the egg from which she was raised being, as I supposed, three days old when started. The other queen cells, nine in number, were at once destroyed. This year, on the afternoon of June 30th, I removed all the combs and the queen from my observatory, giving the bees two large combs of Italian brood. Next day I found queen cells commenced on both combs. Thinking it impossible for a queen to emerge from her cell earlier than the thirteenth day, I intended to remove these combs on the twelfth day and use the young queens in other hives; but on the morning of July 11th—i.e., a little over ten days after introducing the combs, I found a young queen at liberty, and all the cells on the same frame torn open. In the middle of the same day I removed the other comb with four queen cells uninjured (the new queen not having found them), and gave them to other bees. I thus proved without doubt that it was the young queen herself who commenced destroying her rivals. But will some more experienced apiarian kindly tell me what becomes of the theory that a queen takes sixteen days to hatch, and that the process must be commenced before the egg is over three days old?—J. B., Maiden Newton, Dorset.

HONEY SEASON IN NORTH STAFFORDSHIRE.

"I SHOULD like to know what sort of season this has been for bees in the southern parts of England. It has been a very bad one in this locality (North Staffordshire). Swarming commenced here on the second week of June. Half the number of hives in this neighbourhood never swarmed at all. From eleven stocks I have had six swarms only. Two of my non-swarmers have filled ekes and are again clustering outside in great numbers.

What must I do with them? Would you put more ekes under them?—R. W. J."

If our correspondent intends to take his bees to the heather, which is plentiful enough in North Staffordshire and the adjoining county, his hives should be eked or supered before their removal. His non-swarmers are strong in bees and capable of great feats on the moors. Bees do not usually gather much honey from clover later than July; ekes, however, may be used for shelter to the clustering bees. By-and-by the bees will sit more closely together, when the ekes may be removed.

We hope some of our friends in the south are able to send better accounts of bee-keeping this year than those of Staffordshire and Cheshire.—A. PETTIGREW.

OUR LETTER BOX.

FOWL'S FOOT SWOLLEN (*J. Hobbs*).—Have the floor of the fowl house covered 2 or 3 inches deep with sand, and do not let the fowl roost, but sleep on the sand.

MALAYS AT THE ALEXANDRA PALACE.—I have received the following amounts towards the prizes in the Malay class:—Mr. Stanley, 10s.; Mr. S. B. Perry, 7s. 6d.; Mr. A. Smith, 5s.; Mr. G. Burnell, 5s.; Mr. Lecher, 10s.; Mr. Hawkins, 2s. 6d.; J. Hinton, 5s.; Mr. T. B. Lowe, 5s. I shall be obliged to any Malay fanciers for a letter to help in swelling this amount.—JOSEPH HINTON, Warminster.

CHICKENS PARALYSED (*A. E. N.*).—They are fed too stimulatingly, and are grown too fast. Indian corn in the morning and barleymeal mash at night would be quite enough as they have a grass run.

YOUNG TURKEY BLIND (*C. L. M.*).—Wash the head daily, or twice daily, with tepid water. Give sulphates of copper, one grain, mixed in oatmeal mashed with ale, and plenty of green food. Separate the bird from all others.

LICE ON PIGEONS (*J. T. P.*).—Dust thoroughly under their feathers and their nests with flowers of sulphur.

RHUBARB WINE (*E. F.*).—Take 5 lbs. of rhubarb cut as for tarts, then add to such quantity one gallon of cold water; place it in a tub or vessel, where it may remain eight or nine days, taking care to stir it well up at least two or three times a day; then strain it off, and to every gallon of liquor add 4 lbs. of loaf sugar, then juice of a lemon, with part of the rind of the same; put it into the cask with a little isinglass dissolved. The cask must not be stopped down for a month, and you may bottle it in ten or twelve months.

REMARKS.

25th.—Fine morning and forenoon, dull afternoon and evening, and rain after 9 P.M.

26th.—Raining heavily at 9 A.M., but soon clearing off; the remainder of the day fine, and the night splendidly bright.

27th.—A fine pleasant day throughout.

28th.—Grey morning, and rather so all day; a slight sprinkle of rain about 4 P.M.

29th.—The finest and hottest day we have had for some time, but there was a pleasant breeze to temper the heat.

30th.—Grey morning, but a brilliant and hot summer day, but still a pleasant breeze.

31st.—Morning and forenoon very bright; afternoon and evening rather cloudy, but the heat intense and scarce any movement in the air.

The last three days excessively hot, and this more trying as the temperature previously had been rather low.—G. J. SYMONS.

COVENT GARDEN MARKET.—AUGUST 1.

PRICES remain the same as last week.

From observations taken near London during forty-three years, the average day temperature of the week is 75.0°; and its night temperature 50.0°.

CLOSE PLANTING VINES—ALTERNATE CROPPING.

OCASIONALLY Vines are planted at half the usual distances apart with a view to a fuller and earlier supply of Grapes, and the plan was at one time advocated as not only calculated to secure greater first results, but by alternate cropping of the Vines it was thought to possess permanent advantages.

"J. W.," some time ago, requested information upon this subject; but I did not think it desirable to respond until fortified with at least an apprenticeship of experience.

In the spring of 1870 I took charge of two vineries with the Vines planted 27 to 30 inches distance apart. They had been pruned to the bottom of the trellis, and all eyes removed but the three uppermost. The object was to have fruit quickly—a means wide of the mark for securing it, inasmuch as had every other Vine been a fruiting one and fruited in the pot placed on the border, or, better, the hot-water pipes, and well fed, a dozen bunches might have been had from each Vine the first season; but under the circumstances no more could be anticipated than proving of the kinds, to which wrong labels had been attached to several.

In 1870 the Vines reached the top of the house, and laterals being rather freely encouraged they had in autumn strong well-ripened canes. These were cut back to one-third their ultimate extent, the object being to have them in full bearing as speedily as possible—in full crop in three years after the first. The rods were depressed early in 1871, and as bleeding took place the ends of the canes were dried with a red-hot iron and then smeared with the patent knotting used by painters. The break was good; every shoot showed fruit, some two and three bunches. The shoots were disbudded, reserving shoots 18 inches apart on each side, or as near as they could be had at that distance, and a bunch of fruit was allowed on each. Ample laterals were allowed from the leaders, and the finish was satisfactory.

1872. The Vines fruited two-thirds the extent they were to occupy, and were quite equal in finish to the preceding crop. In 1873 the Vines were in full bearing, allowing each Vine a full crop, twice the quantity of fruit to what would have been the case with half the number of Vines; but the finish was not so good as in the two first years of fruiting, it being clear that the foliage was already becoming too crowded.

1874. Smaller bunches, smaller uneven berries, and indifferent finish marked the produce of this season; plenty of fruit, but unsatisfactory. If failure was to be avoided prompt steps must at once be taken. Half the produce of the Vines would have made a serious void in the supply, otherwise out at once would have come every other Vine; and I have no question as to the effect upon the remaining Vines, for with more space the foliage would not only be larger but be more able to perform its important functions. Things must remain as they were for at least another year.

In 1875 I took a shoot from the base of every other Vine and trained it along the rod to the top of the house, stopping the laterals to one leaf. These Vines, notwithstanding the increased foliage of the cane—greater crowding of the foliage—finished their crops better than the other Vines. When the fruit was cut the old rods were cut away and the young canes took their places. A strong well-ripened cane with roots that had supported it and a rod with spur shoots carrying twenty bunches of Grapes in 1875 ought to produce the like quantity of fruit in 1876. I had previous experience upon the matter, and resolved not to try it again, inasmuch as though a cane would afford twenty bunches of fruit, it became so exhausted in the performance as to be of no further use—at least not without resuscitation of its energies by a period of rest: therefore I left the cane one-third its length, and had a good show of fruit, but considerable divergence in character upon the kinds grown, which as it appeared to me interesting I may note. Black Hamburgh, Mill Hill Hamburgh, and Buckland Sweetwater were very loose in the bunches, indifferently furnished with berries for their size, and had a large per-centage of small seedless berries. Muscat Hamburgh (Black Muscat) though the bunches were large contained many stoneless berries, not many of which were full sized. Lady Downe's were in a similar state, yet having larger bunches than from spurs. Mrs. Pince, Gros Guillaume, and Trebbiano afforded good bunches, but were stamped with a looseness of bunch and seedless berries, yet not to an extent that a good thinning did not rectify. The finish of the cane fruit was not so good as that of the spurred rods, which showed a decided improvement in 1876 over the crop of 1875, the greatest advance being in Muscat of Alexandria, Gros Guillaume, and Lady Downe's; those with Mrs. Pince and Trebbiano requiring more space for their foliage than Hamburgs, and Hamburgs demand more foliage space than the Frontignan, Sweetwater, and Muscadine Grapes. I may mention White Frontignan as not showing any improvement from having increased space; but as the crop was good and had been equally so from the first no complaint can be lodged against it, indeed I find it one of the best kinds for early forcing. This season the rod Vines have so improved that the cut-down Vines between them will, so soon as the crop from them is cut, be cleared out.

It has been asked if there is any fear of the roots of Vines left in the soil engendering fungus to the injury of the roots of the remaining Vines? I have no dread of such an occurrence—in fact I have taken often away much older Vines, and found no evil results attend the leaving of some roots in the border. They will decay no doubt, the decay causing a nidus for some fungus to vegetate in, hastening the work of decomposition, that itself being of a kind as likely to benefit the Vines as to prove injurious, at least I have not experienced any injury to Vine roots by fungus generated or fostered by decaying roots. I have therefore not had cause to fear any evil from fungus in a Vine border.

Nothing is gained by the close planting of Vines, unless

the object be to obtain the greatest result in the briefest period, rooting out the Vines afterwards; nor is anything good had by crowding the foliage, every leaf requiring full exposure to light and air for the due performance of its functions—the perfection of the present crop, and the no less important condition of perfecting growth for producing future crops. A great Vine is not necessary: of more consequence is the exposure of the foliage fully to light and air, and when this is provided, with the other elements of culture, a Vine in a ground vinery or an amateur's small greenhouse will afford Grapes of equal quality with the giant of Cumberland Lodge or the mammoth at Hampton Court.

I may inform those who differed with me as to Gros Guillaume being a shy bearer, that it still maintains the free-bearing property attributed to it some time back. It bears freely, one critic said, whilst the spurs were young; another gave instances of its shyness of bearing. I do not know what may be called an old spur. I have seen spurs 2 feet and more long; but not being an advocate for more old useless wood than is absolutely necessary to act as conduits of the sap to the bearing parts, my spurs are short, though not so short as I could wish, or they would emanate from the main rod annually; yet I have spurs upon Gros Guillaume of seven years' growth producing in each year a bunch of fruit, the show of fruit being as good upon the shoot from the first spur at the base of the Vine as at the top. This year the largest bunch is at the base of the Vine, the bunch measuring 18 inches in length and 16 inches across the shoulders; those at the top are not more than 16 to 17 inches in length and 13 to 14 inches across the shoulders, the Vine itself not having a rod much over a dozen feet in length, yet it carries eight such bunches, and ten equal to them were cut away when thinning. All it requires is to have the foliage ample, and the shoots thin, so that the wood becomes perfectly ripened, and it then fruits freely.—G. ABBEY.

VARIORUM NOTES ON ROSES.

GOING about as I do all over the country exhibiting and judging, I have many opportunities of taking notes of persons and things, and the longer I live the more I learn about Roses, their requirements, their strength, and their weakness. It occurred to me that perhaps at this dull time of the year a few notes might be acceptable to the Rose Journal on the subject of Roses viewed in an exhibition light.

It may be remembered by some of your readers that in one of my former letters, before the exhibition season commenced, I expressed my anxiety as to the result of this season's exhibition to myself, inasmuch as I had made rather a bold experiment. I determined for once to grow my Roses without dressing them with farm or other manure in the autumn or spring. I was led to adopt this plan—first, from a visit paid to me by Mr. Walters of Exeter, who expressed his opinion that my soil had been so manured of late years that it could not hold any more; secondly, from the difficulty and expense of procuring manure; and thirdly, from the untidy appearance that the beds assume when the manure is left on the surface. I therefore relied entirely on guano in the spring, surface-moving, and any amount of liquid manure. Concerning guano I know there is a great difference of opinion. Many people hold that it is of no use at all for Roses, others say that it is beneficial, but must be employed with the greatest caution. I hold that guano is one of the finest manures for Roses we have, and my experience this year (to my mind at least) proves it.

I pruned very late in order to suit the National fixture, and I am confident that here I made a great mistake. When I say late, I mean late for this neighbourhood, for it was the middle of March before I pruned a Rose. Anyone who remembers the late season will, I think, agree with me in saying that we had a mild if not a very mild winter. February was so mild (for the season) that the Rose trees grew wonderfully, and when I came to cut them they were almost in full leaf, at least the leaves were all formed. I then cut tremendously hard, almost down to the ground. The check here must have been very great, but after the pruning was finished a season of unexampled severity set in which checked all growth, and so naturally my plants refused to grow. The very maid servants here shook their heads as they saw such hard pruning to plants in full growth, and I am convinced that, be the shows when they may, it does not do to defer pruning to suit them. In the first week of June I looked round my roseries and saw no growth, no buds, and no signs of being in form. Then in desperation I called Peru to my aid, and put on the guano very carefully

and in small quantities, and though my plants did not grow at all as they ought to have done I had fair blooms. Every rainy day (we had only three all June and till the 15th of July), I put on guano again. Now as to results. I think anyone who has read my accounts of shows will absolve me from any wish to speak of my own success, and believe me that I only mention what I have done to "point the moral and adorn the tale."

I showed at the Crystal Palace in one class, at Exeter in two classes, at Torquay in four classes, at the Alexandra Palace in two classes, at St. James's Hall in four classes, and at Bristol in five classes—eighteen classes in all at the great shows; and I won three first prizes, eight seconds, two thirds, and three fourth prizes, or sixteen prizes with eighteen exhibits. This, of course, is not in any way a grand result, but just a decent success; but it has been achieved without the employment of a single load of stable manure, and I only mention it to show that, where it is almost impossible to procure this, something may still be done with artificial aids like guano.

I must also mention in self-defence for not doing better, that owing to our having no late trains on the South-Western Railway, I am compelled to cut either fifteen hours before my great rivals do, or else to cut and stage in the hot sun. And this leads me to the discussion of a point of much interest and importance to men who, like myself, are obliged to cut a long time before our rivals. Is it better to cut at 3 A.M. with the dew on the blooms, or to wait till 2 or 3 P.M. and cut in the hot sun? What say the authorities?

Mr. Keynes says, or did say some seven years ago when asked by myself, "Undoubtedly it is better to cut in the early morning, even twenty-four hours before the show, than to cut in the sun however near you can do it to the time of judging." Mr. Keynes' foreman said last week when I told him that my Alexandra trebles were cut in the sun, "Well, sir, and if you have the stuff in your Roses it is best to do so." Mr. Curtis, I am told, positively recommends it; Mr. George Paul condemns the practice; and Mr. Robert Baker, the champion, says that under no circumstances would he cut in the morning. He always is able to cut at night; but if he were not, he would cut in the sun rather than at three or four in the morning. "There is one thing," he added, "one advantage you have in cutting in the sun—you need never put in a bad bloom," and when cutting in the early morning young blooms to last for thirty hours, you often do; in fact, you cannot fail to put in some poor blooms. However, the idea of cutting in the sun is quite new. It is like Wagner's music, violates all established rules, sets custom at defiance; but whether it, like his music, will prove to be the "rage of the future," or whether it will even be scoffed at then as it is now by the great majority of rosarians, remains to be proved. My own idea at present, and one which I shall follow out with extensive practice next season, is to cut very young and cut in the sun, unless the South-Western Railway mend their ways and carry the mails instead of being content to see them carted thirty miles as now away from their system. Any advice that your correspondents will kindly give on this momentous question through the winter will be of great service, and be most highly appreciated by a Wyld Savage. The great charm, or at least one of the great charms of the National Rose Show at St. James's Hall, was the great freshness of the blooms. Mr. George Paul cut as late as he could see the night before the Show, and travelled up slowly, and quietly, and coolly during the soft night air. Mr. Turner cut all his blooms the morning of the Show; and Mr. Cant not only cut very late on the eve of the Show, but also left his foreman to run over his plants and bring-up fresh blooms on the following morning. Here, then, were three of the great nurserymen showing blooms many of which had only been cut five instead of the usual twenty-eight hours.

And now let me give one or two instances of the great energy shown by the leading amateurs so that their blooms might be as fresh as possible at the great tournament of the year. Mr. Jowitt loaded his Roses on his own trap at Hereford, had the trap placed on a carriage truck at the station, and did not unload it till he carried his boxes into his own private dressing-room at St. James's Hall. His great rival "Hercules," who ran him so close at the National for the cup and beat him on his own ground at Hereford, positively iced all the water with which his tubes were filled, and he took a spare bloom for every Rose he staged. He showed in thirteen classes and took £32 in prizes. Was ever such a wonderful success known? Next year Mr. Cranston's cup at Hereford and also at St. James's Hall will be keenly competed by these

two giants, and the contest even at this distance of time is talked about, and is the cause of much interest and excitement. Looking back over the exhibitions and comparing notes I am struck with one thing which is of rare event, and that is the number of excellent new Roses which have been exhibited this year. By new Roses I do not mean plants sent out this year, but those of the two last years. Both from France and England good novelties have been put in commerce, and we cannot be too thankful that this is the case when we remember what a lot of rubbish is usually sent.

Abel Carrière is a great acquisition to the Pierre Notting class of flower, while Avocat Duvivier is equally good. Mr. George Paul's seedlings are all great gains to this class of colour, particularly Duke of Connaught and Sultan of Zanzibar. Madame Prosper Langier and Madame Emilie Verdier are most important additions to our rose and carmine shades, while Marguerite Brassac is a worthy partner of Charles Lefebvre. Monsieur E. Y. Teas is all that can be wished in a Rose, and too well known to require description. Mr. Turner's Royal Standard and Mrs. Baker are gems of the first water, and these with Duchesse de Vallombrosa and Souvenir de Arthur Sansal make a quartet of light beauties quite worthy of the company of Monsieur Noman, Marguerite de St. Amand, and Mdle. Marie Cointet. Mr. Cant has given the Rose world a priceless jewel in Prince Arthur, and many other French Roses will prove, if I mistake not, worthy of a place in the best stands.

Among new Teas Marie Guillot, concerning which a correspondent inquires, is in my opinion—and one which is founded on much experience—positively worthless out of doors. It is a splendid grower, and perhaps indoors would do well, but in the "open" she will not open. It may be punning to say so, but it is strictly the truth. I have given the Rose the best and fairest trial I can. I have grown her under a south wall in the sunniest and most sheltered spot in my garden, and I have a splendid lot of standards with an eastern aspect, and also another lot with a south aspect, and wherever they are they disgrace the rosery. They grow, they form huge intensely double buds, but when these try to open they cannot perform the operation; it is too much for them, and so they become first dirty and then die. Shading I do not think would do any good, but perhaps a magnifying, or what schoolboys use and call a "burning" glass might. I have as yet seen no good new Teas shown. I was not at the Alexandra, but was at all the other shows except Hereford, and no nurserymen staged any new Teas. So as far as I can judge there are none worth growing. This, if so, is a great loss, as we are very much in want of a few new good Tea Roses. For the last eight years at least no English nurseryman has produced a new Tea, always excepting Mr. George Paul's Hybrid Tea Cheshunt Hybrid, and I cannot understand how it is when he and Mr. Charles Turner have produced so many good Hybrid Perpetuals they cannot send out a new Tea. Is it that the seed will not ripen? or are the Teas barren in England? or what is the reason? Depend upon it the English nurseryman who does produce a Tea Rose which will rank with Catherine Mermet or Marie Van Houtte will have earned undying fame, and be the greatest benefactor that the Rose world has ever known. Devoniansis was an English-raised Rose, and came from fair Devon. Why, then, cannot we have more of the same sort? Perhaps some learned gentleman will answer to illuminate the ignorance of a—WYLD SAVAGE.

POTATOES.

I AM growing upwards of thirty sorts this year; some of them are quite new, and some are to my certain knowledge fifty-eight years old. These are London Don, Blue Don, Glasgow Buff, and Perth Red. Those sorts up to 1845 and 1846 were in general use, and they were very fine, but they are apt to be badly diseased in wet seasons. They are now very little grown. I think if they were grafted on some free-growing sort, such as Champion, that in a few years they might be restored to their pristine vigour, and it is worth trying.

Some of the new sorts I am trying. Alpha seems to be a useful early sort, and not a robust grower. The foliage is not the least curly, it is 18 inches high. Schoolmaster is growing very freely, and is about 2 feet high, but it does not look to be so early as Alpha. Covent Garden Perfection grows freely, and is 14 inches in height. Yorkshire Hero is growing well and full of promise, and is about 2 feet high. It appears to be like the Lapstone Kidney, which is a very fine sort. Porter's

Excelsior was recommended to me by a nobleman's gardener of high standing, and I bought a stone of it, but it seems a puny-growing sort, and is not above 7 inches high. There are a few amongst them, one out of twenty, that grows more freely and is 14 inches high, and though they are growing beside those named, and have the same treatment, they look like Pharaoh's lean kine among the strong roots. Climax is not very new, but it is new to me, and is much grown by the market gardeners for the Edinburgh market. It is 2 feet high, has fine full foliage, and is very promising. Extra Early Vermont, a sort very like the American Rose, is equally promising, but I have grown it for the third time. I sold some this season for seed at 24s. per cwt. They left me a good profit. When I lift the crop I will give you an account of them.

I saw a patch of blight this week on the Early Vermont; the haulm was much decayed, and some of the roots were rotting. The position was rather damp, and sheltered by Currant bushes. The weather is now dry and rather cool, and I hope there will be no more of the disease.—J. ADDISON, Ormiston, Edinburgh.

A GARDEN LUXURY.

THE Ashantee hammock of Messrs. Seydel & Co., which has found favour in tropical countries by travellers and others, is adapted for use on the shady lawns of English gardens.

Fig. 24.

Especially, perhaps, by invalids it will be cherished for the comfort it is capable of affording to them; and if those who are unfortunately more or less afflicted can enjoy it, it can be

Fig. 25.—Ashantee Hammock Suspended.

enjoyed the more by those who are hale and hearty. It has been awarded a gold medal at the recent Oporto Exhibition. As a garden requisite it is alluded to, and the accompanying figures show its nature and appropriateness as a garden appliance during the summer months.

STRAWBERRIES FOR LIGHT SOIL.

A FEW years ago there was a Strawberry election in the Journal, and several interesting and instructive letters were published from correspondents on Strawberries and their cultivation in vol. ii., 1872. I was induced to try three or four fresh sorts, and have now given them a fair trial, and propose to say a few words about them; but in the first place will refer to Keens' Seedling. This sort I have had a long time, and it is undoubtedly the best early Strawberry. I have a bed 8 yards long and 7 wide which has produced about seventy quarts of Strawberries this year, and nearly the same last year. This bed has been down about eight years, and the plants look likely enough to go on for another eight. There is nothing particular in the management. They are 2 feet apart, and annually manured with well-decayed hotbed manure. They are trimmed up in autumn, and all the leaves cut off but about five or six at the top. The manure being thoroughly decayed, there is never any necessity to rake it off. The fork, as a rule, is never used, but there was an exception this spring. The soil was rather caked over on the top of the bed of which I now write, and it was dug over with the point of a small

border fork with advantage. The fork went into the ground deeper in the centre of the alleys and very shallow close to the plants. Even this small disturbance would be injurious to one-year-old plants.

The newer sorts I have tried are Early Prolific, Sir J. Paxton, President, La Constante, Eleanor, and Wonderful.

Early Prolific is a fine good-flavoured Strawberry, but is not robust enough in growth to please me, and rather uncertain; but it is about a week earlier than Keens' Seedling, so that either the Prolific or Black Prince must be grown. A very good plan is to plant them side by side and see which will answer the purpose best.

Sir J. Paxton and President have done exceedingly well this year. The former is a noble Strawberry and worthy of all the praise given it at the election. President is also a good Strawberry, rather later than the other, but not equal to it in my estimation. La Constante is a fine-flavoured fruit of dwarf habit, very useful for a shady part of a garden. Wonderful, *alias* Myatt's Prolific, I have seen well spoken of by some people and very much found fault with by others. I have given it a fair trial, and planted out a long single line running east and west. The plants were manured in the autumn, and the fruit branches supported with little forked sticks and kept apart from each other, and some wire pea guards put over all to keep the birds off, which by the way are excellent for the purpose. There certainly was a wonderful quantity of fruit showing at one time, but the performance was not equal to the promise. There was a fair crop of fair-flavoured fruit without any green tip. It is only a second-rate Strawberry, and I should not care to grow it as long as better kinds succeed well; but it is quite possible it may be useful in gardens where manure is not available.

Of the late kinds I need not say much, but I wish we had some later still. The Elton Pine I have had a long time and it does very well; it is the best late Strawberry here. Frogmore Pine and Eleanor have been recommended; the former is a very good-flavoured fruit, but it is not late enough, or I have the wrong sort. Eleanor I do not very much like at present, but must give it a further trial. It may turn out rather later than the Elton; if so, it will be an acquisition.

I gathered the first dish of Strawberries on the 30th of June, Early Prolific and Keens' Seedling nearly together this year, and the last on the 3rd of August, principally President. There will be a few more stragglers.

Since writing the above I have seen the remarks of "W. S. P." I regard the annual renewal of beds as only a last resource, and is certainly not desirable except in a few places. I do not think with any amount of care I could obtain half the crop I can from established plants. Two feet apart I think a very good width, but when there is a very large crop, like there was this year, you cannot gather the fruit very well, and have to pick the fruit all round you and clear a space with your hand before you can set a foot anywhere. I think it would be better to leave a foot of extra space between each third row to enable you to gather on each side. Keep the plants at all times free from weeds, but on a light soil beware of letting in the rays of the sun too much. In a very dry season I do not cut off the runners in early summer, or trim up the beds in autumn unless the soil is sufficiently moist, but wait for rain.—*AMATEUR, Cirencester.*

THE ROSE YEAR.

AMONGST the Rose lore of the Journal I am gratified by finding that Roses for garden decoration as well as Roses for exhibition are still cherished by many. Yet, we have a rosarian—a modern orthodox advanced rosarian—who grows hundreds, perhaps thousands of Rose trees—no, "plants," and who on the 23rd of July writes a valedictory account of "the year that is just over"—the Rose year of 1877. Without applying a stronger term, I will say that the admission of "WILD SAVAGE" is a libel on the Rose. He has told us that he was not "in" at the Crystal Palace Show (June 23rd), and "out" a month after that date. Thus he has had about three weeks of Roses for forty-nine weeks of preparation. Fancy the drawing-room of a rosarian being destitute of Roses for forty-nine weeks out of the fifty-two! If Mrs. Savage can endure that without a murmur she must be possessed of anything but a savage disposition—must, indeed, be angelic. Why, few prisons—I mean the governor's quarters—can, I think, be so destitute, and I trust no hospitals are roseless for such an unreasonable time. Have I placed the matter too

strongly? Let me quote "WILD SAVAGE'S" own words. On page 47 he has stated, "For fifty weeks in the year the whole of my front has looked hideous," and at the time of writing that gloomy sentence he gives dismal emphasis to the circumstance by saying that he had then "nothing in the shape of a flower," nothing for poor Mrs. Savage's drawing-room except (it is only right to mention this) the lovely Teas.

Let me ask that some spare corner, some place unfavourable by site or soil for exhibition Roses, be vouchsafed for garden Roses—drawing-room Roses, and so make the garden less "hideous" and the room more cheerful. I can enjoy a perfect bloom and an exhibition of Roses, and am willing to admit that few sights are more beautiful, more imposing, but I cannot admit that Rose shows should be the be-all and end-all of Rose cultivation.

I earnestly hope that there are hundreds besides myself who do not regard the Rose year as being over, but hope to enjoy in gardens and rooms hundreds of Roses for months to come. I am happy to say that if there were no Teas the drawing-room that I have catered for during several years would never have been without Roses from the beginning of May, when a few are produced in the greenhouse, until Christmas. Surely if "WILD SAVAGE" can grow hundreds of "plants" for producing exhibition blooms, he can afford space for a few trees and bushes for yielding drawing-room flowers, and so remove what I think is the reproach that now rests on his garden.—*A PARSON'S GARDENER.*

IN THE NORTH.—No. 1.

HOWICK HOUSE, PRESTON, LANCASHIRE,

THE SEAT OF T. M. SHUTTLEWORTH, ESQ.

It will have been seen that my steps have again been northwards, and although Preston was taken in my homeward journey, yet there are reasons why I should give my notes of it first. It is well known that the provincial meeting of the Royal Horticultural Society is to be held there next year, and that Mr. Shuttleworth is to be the local Secretary; but it is not equally well known that a Company of which he is Chairman has guaranteed the sum required by the Society's arrangements, and that thus one material difficulty has been got rid of; and anyone who knows the indomitable energy and pluck which characterise him is thoroughly persuaded that there will be no *fiascos* as at Bath, and that the comfort and convenience of all concerned will be considered. Beyond this step and the securing of a place for the Show, which will be held in a field of twenty-two acres about two miles from the town, but little has been done; in a short time, however, we may expect to see the usual announcements and a liberal prize schedule issued. Preston, like most of these northern towns, is not an inviting place, and I can hardly imagine anyone choosing the town itself as a place of residence, but it affords many facilities for an exhibition. It is central, in the midst of a dense population who are given much to holiday-taking; and there is no doubt if the one element on which everything of the kind depends—if weather be favourable, that the meeting will be a very successful one.

Howick House has only been in the possession of Mr. Shuttleworth for about four years, and during that time has been metamorphosed, although the alterations are not yet completed. The house is an old-fashioned roomy residence with no great pretensions to beauty, but pleasantly situated, and has within it the elements of being, what I have no doubt it will be by-and-by, a perfect place. The soil is a rich deep loam, in which Roses and Strawberries grow to perfection. Two large beds of dwarf Roses were wonderful for their vigour, and I should not be at all surprised by-and-by to find the Roses from Howick occupying a distinguished place. Of this I am sure, if once the idea seizes my good friend he will not rest until he is at the top of the tree, and no Hercules or Agamemnon or any other hero will deter him; and I say this from what he has already done. In the course of a few years he has become one of our leading exhibitors of plants, has carried off a number of Mr. Bull's cups, has won the ladies' gold medal at Preston, and the gold medal at the International at Dundee, and the gold medal at the last great summer show of the Royal Horticultural Society; and no one who saw the splendid examples of foliage plants then exhibited could doubt that the position attained by Mr. Shuttleworth was rightly his due. Like many another exhibitor he has worked his way up. He is fond of telling his own story, how some years ago when he was a greenhorn he had sent some twenty entries to a provincial show, and feeling that

as he had a good deal of the toil he ought to have some of the reward, he wrote to the secretary to say that it would be better to forward him a cheque for the amount of his prize money. This was quite impossible, not from its large amount but the reverse, as it amounted to 9*d.*—somewhat different to his last Manchester winnings, which amounted to £70. Still, perhaps that "miserable nineness" was the spur to urge him on.

During the four years the present range of houses has been erected and further alterations are in progress. These houses are filled with plants, every one of which is a specimen in itself, and they are interesting to those who know the excellence of culture which is required to bring plants to this perfection; and here are to be seen those giants by which his renown as an exhibitor has been obtained.

Amongst the plants for which Howick House is famous the *Gleichenias* hold a foremost place, and I am not quite sure but that they are the favourite plants of the owner; nor will it be too much to say that such a collection is nowhere to be seen. The grand masses of *G. semivestita*, *flabellata*, *speluncæ*, *pectinata*, *rupestris*, *circinalis*, &c., were in vigorous health, most of them 7 and 8 feet in diameter, and not the least surprising fact is the short time in which these grand masses are developed. When in two or three years plants fit for exhibition can be obtained it must be clear that their culture is well understood. The plants were also perfectly clean, no appearance of thrips or any of the ills to which plants are subject, and not a little of this is to be attributed to the fact that they are grown in a much lower temperature than is usual. Because they come mostly from the southern hemisphere they are treated often as if they were tropical plants; but Australia, New Zealand, and Tasmania are not tropical countries, and if plants indigenous to those countries can be kept in a lower temperature free from frost they will do well. The climate of the Genoese Riviera, as Dr. Bennet tells us, is favourable for all Australian plants, and so Mr. Shuttleworth is but following nature when he refuses to treat the greater portion of them as stove plants. *Cyathea dealbata* with its silvery fronds is very fine, and so is *Cibotium princeps*, one of the grandest of Ferns. Then *Todea superba* is in such condition as it is rarely seen in—magnificent fronds of the liveliest and brightest green. But Mr. Shuttleworth's love for Ferns is not confined to exotics; he has a choice collection of British Ferns, many of them of large size, which have already gained exhibition honours, and doubtless are destined to do so again. In the same house are two grand specimens of *Cordylina*, one of which is I suppose unequalled.

And what magnificent stove and greenhouse plants are to be found in all directions! Here is a plant of *Phormium tenax variegatum* so large that it has to be kept tied in. Then the *Staticeæ* with their masses of lavender-coloured flowers were especially gay, preparing, too, for contest in another field. Then there are plants of *Croton* marvels of beauty, amongst them a fine plant of *Disraeli* with leaves nearly 2 feet long with golden yellow midrib and a few scattered spots of the same colour; *Croton spirale* with its curiously twisted leaves, and many others. Here again are fine plants of *Dipladenia amabilis* with its lovely pink flowers, also of *Dipladenia Brearleyana*, a most floriferous kind, with the flowers of a much deeper crimson than in any other variety, diffusing its delicate perfume through the house. There are also grand plants of *Eucharis amazonica*, and of the, if possible, still more useful *Eucharis candida*—more useful because smaller, and therefore more suitable for bouquets, as I have seen many otherwise very beautiful spoiled by a centre flower of *Eucharis amazonica*. Seldom, too, have I seen a more beautiful specimen of *Maranta Veitchii*. Larger I have seen, but they have too often been ragged and discoloured; this was clean and sound. Heaths, too, which we do not often see now well grown, are here in capital condition. Two lovely plants of *Erica Parmentieri* and *Parmentieri rosea* in full flower make one sigh over those days when they were so generally grown and exhibited in such perfection. One of the finest plants of the lovely *Lapageria alba* that I have seen is here, a plant, I think, only three years old, with six strong suckers from it, and likely soon to be a mass of beauty. Then there are *Zamias*, *Dions*, *Dracenas*, &c., all in first-rate order, and all grown for exhibition. The *Azaleas* are grand in size and in rude health, the masses of *Anthurium Scherzerianum* in magnificent flower; and it was with some interest I saw the place where the seeds of this plant did unquestionably settle the rats—a too valuable cure, I fear, to be used generally, but apparently most effectual. *Camellias* too are in fine order, and in fact to enumerate the plants would be simply to go

through the lists of those stove and greenhouse plants which we see on all great occasions; and I am convinced that, both at Carlisle and Preston, whoever crosses swords with my good friend will find that they have something to do to beat him, for the cleverest plantsman will find him a foeman worthy of his steel.

The zonal *Pelargoniums* grown for exhibition are grown in a low span-roofed structure, the sides as well as the roof being of glass, the plants raised up close to the top so as to give them abundance of light and air. This had resulted in the production of plants of large size, great freshness of foliage, and abundant promise of bloom, and in them, as everywhere in this plant, excellence of culture is the rule. Of course it is not everybody who has the inclination, and I may add the means, to enter so largely into the growth of exhibition plants; and I could not help thinking as I walked through the houses and surveyed these plants, how much do the promoters of flower shows owe to such enterprising growers. It is commonly thought that the balance is on the other side, but I am convinced this is incorrect. A gentleman of Mr. Shuttleworth's tastes might very well do without flower shows, but flower shows cannot do without him; and if committees were to consider these things a little more they would perhaps endeavour to make themselves more agreeable to exhibitors instead of imagining that the exhibitors ought to be vastly obliged to them.

I have endeavoured to give some little idea of the character of this place, but, as I have said, it is in transition; and if any of the visitors to the Preston Show next year find their way to it, as I have no doubt many will, they will find it much altered. Mr. Shuttleworth has a thorough knowledge of plants himself and is a really practical gardener; but it would be unfair not to bear witness to the intelligence and zeal displayed by his head gardener Mr. Thornber, for to him must be attributed in good measure the excellence of the collection. Master and man work well together, and success is the result; and I may, without injury to others, wish more of that success to the hearty, genial, and hospitable master of Howick.—D., Deal.

ROSES IN SCOTLAND.

"A Rose bud by my early walk
Adown a corn-enclosed bawk,
Saw gently bent its thorny stalk
All on a dewy morning."

"It's a far cry to Loch Awe," and so it is from Galloway to Fleet Street, but as you have had news of Welsh Roses perhaps you can find room for a few notes from Scotland. Year by year the culture of the Rose is extending rapidly in this country, and nowhere perhaps more rapidly than in this south-west corner of the "land of brown heath and shaggy wood." I live (is it not written in the book of "D., Deal?") in the very windiest spot in Britain, and I try to grow Roses, and my friends and the local prize lists say I succeed. If, then, it be of any interest to your readers here is a list of Roses which are "certainties," even in such a trying place for rude Boreas and his kindred crew as this wee garden of mine:—*La France*, *Marquise de Castellane*, *Cheshunt Hybrid*, *Alfred Colomb*, *Jules Margottin*, *Baronne de Maynard*, *Marguerite de St. Amand*, *Baroness Rothschild*, *Bessie Johnson*, *John Hopper*, *Duke of Edinburgh*, *Maurice Bernardin* and his *confrères* *François Michelin*, *Mdlle. Eugénie Verdier*, *Marie Finger* (these two are here certainly distinct in colour, and the latter superior to the former), *Centifolia Rosea*, *Anna Alexieff*, *Madame Lacharme*, *Madame Knorr*, *Homère*, *Souvenir de la Malmaison*, *Marie Baumann*, *Princess Mary of Cambridge*, *Madame Berard*, *Senateur Vaisse*, *Thorin*, *Vicomte Vigier*, *Comtesse d'Oxford*, and *Thomas Mills*. On a wall I find *Belle Lyonnaise facile princeps*, then *Devoniensis* (both kinds), *Rubens*, *Bougère*, *Goubault*, *Duchess of Edinburgh*, *Madame Willermoz*, *Safrano*, *Catherine Mermet*, and *Triomphe de Rennes* do best, though I find the blooms on the last-mentioned Rose very small this year. The *Maréchal* after a three-years trial I give up. I admit he is a glorious Rose, but the swirl round the corners of my domicile is too much for him. "D., Deal," says, *Grow Rêve d'Or*, and so I will. I grow many other kinds, but the names given are those which do best here, and doing well here they will do anywhere in Britain.

Of new Roses I find the following do admirably here:—*Madame Ferdinand Jamin*, *Miss Hassard*, *Mdlle. Marie Cointet*, *Monsieur E. Y. Teas*, *The Shah*, *John Stuart Mill*, *Villaret de*

Joyeuse, Hippolyte Jamin, and Bernard Verlot. I will give other new sorts a further trial, but so far they are a snare and delusion.

In a blacksmith's garden close by me there is the most glorious bush of *Souvenir de la Malmaison* I ever saw. It really is a bush, about 3 feet high and 4 feet through, and is at this moment a mass of magnificent blooms. It is never pruned, only the dead wood cut out. If Mr. Abbey had seen some blooms of pegged-down Cheshunt Hybrid here I think he would have altered his opinion about the size of blooms on pegged-down Roses, and they were not disbudded.

The Galloway Rose Show has given a decided impetus to Rose-growing in this district, and we are greatly indebted to Messrs. Cant, G. Paul & Son, Dickson & Sons, and Robertson and Galloway for the support they have given, and I sincerely trust will continue to give, to the local efforts in honour of the queen of flowers. Mr. Cant, in his genial speech at the Rose Show dinner, told the Galloway amateurs that they were ahead of the rest of Scotland, and truly "approbation from Sir Hubert Stanley is praise indeed." So, fired with enthusiasm by the backing of such a champion in the Rose lists, I venture to hope that some day in the coming Julys we may be able to break a lance with the Sassenach, though Heaven forbid he comes in the armour of a Baker, a Jowitt, a Pochin, or the war paint of the "WYLD SAVAGE," for if he does I fear me much the meeting will not result as did an encounter between Robert the Bruce and Sir Aymer de Valence, Earl of Pembroke, at Glentworth (a lovely spot near here, unknown to the tourist tribe), for this was the end thereof, as the quaint old rhayer hath it—

"And Sir Amery that was wise
Departed in meikle pain,
And went to England home again."

—HOMUNCULUS.

P.S.—I cannot persuade Charles Lefebvre or Madame Victor Verdier to give me the blooms of former days. How is this? I think it would be a great boon in this year's Rose election, if any particular Rose does specially well on a particular stock, this fact were published by adding to the name of the Rose the initial letter of the stock, as M. or S.B., &c. Is this too much to ask from the amateur's benefactor, Mr. Hinton?

WHEN SHALL WE TAKE UP THE POTATO?

THIS is the question that now exercises the minds of all careful cultivators of the noble tuber, and a very important one it is, for success or failure in preserving the crop intact from the ravages of disease very much depends upon what answer our actions shall give to it. Timely lifting saves the crop. It is this important fundamental rule that I have for years been trying to enforce; and now "NORTHERN GARDENER" tells us that it is only to the warm and genial south that my teaching is applicable. I cannot agree with him, and will proceed to show cause why I cannot do so.

Dig up the Potatoes as soon as the tubers stop growing and you will sustain no loss from blight. I have done so most successfully for some years here in the south. Why cannot it be done in the north? Because, says "NORTHERN GARDENER," the tubers swell so late, and there is a lack of convenience for storing them thinly. But if the tubers do swell late that can be no hindrance to lifting them as soon as they cease swelling; and as for the want of store sheds, surely the building of such must be a sound, safe, and wise investment of capital, pointing, as it most certainly does, to an immense saving of wholesome nourishing food. The entire matter is really one of national importance, and it is quite foreign to British energy and enterprise to say that a method of saving an important article of consumption must fail simply for want of convenient storage. How can anyone who is really in earnest suffer such a trifling obstacle as this to stand in his way? I am now in the enjoyment of excellent store sheds. Why? Simply because I showed ample proof for three consecutive years that it must answer to build them let the cost be what it might. When first Potatoes were grown here in quantity there was not a shed or outbuilding of any kind, and yet the entire crop was lifted early and stored thinly. Where? Why, in an old loft over a cow shed about a mile off, which I managed to get hold of while the Potatoes were growing.

Storing appears to be the great difficulty, and yet it is one which I may venture to say could hardly prove insurmountable in a single instance. What after all is required? Darkness to avoid greening, ample space for the tubers to be spread out

thinly, a free circulation of air, immediate protection from rain, combined with subsequent protection from frost, all which are, of course, best obtained in a storehouse replete with shelves, doors, ventilators, and shutters. But failing the storehouse a host of contrivances present themselves. Take for example the case of a grower for the markets, having a field many acres in extent, wishing to lift his crop and store it in the field, sending it thence at various subsequent periods direct to the railway station or markets, and thus avoiding the loss of time and expense which carting at the time of lifting would involve. What can he do? Just this: Make one or a number of beds of earth about 4 feet wide—level, beaten hard with the back of a spade, raised a foot above the surrounding surface, and running the entire length of one side of the field if necessary. Upon these beds the tubers are taken as they are lifted, spread out thinly, and immediately covered with hurdles thatched with straw, and arranged in the form of a continuous ridge, straw being bound over the top of the ridge and up the ends of the hurdles, thus excluding light and rain while allowing a free circulation of air, and affording every facility for the examination and turning of the tubers on fine days. Then when the ripening process is finished they are thrown together in large compact heaps or ridges, a suitable covering of straw or other available litter put on, taking especial care to let it slope at an acute angle so as to throw off rain readily, and the crop is safe.

Let me conclude with a word of warning. When the tubers cease swelling the haulm is invariably green. Let not this prove a hindrance, but lift immediately after you are convinced the tubers have attained to their full size; if you do not and rain sets in, the haulm will put forth lateral or side shoots, the tubers will sprout and produce a crop of other small worthless tubers, thus becoming converted into what are termed seed Potatoes, and losing all excellence of quality, to say nothing of the disease which invariably follows the rain. In a word, the crop will be spoilt, and the time-worn outcry raised once more, How badly the Potatoes are blighted!

Great alarm is being manifested about the Colorado beetle. Well, if it come we must do what we may to get rid of it, but meanwhile let us be up and doing all we can to combat the two certain evils of blight and supertuberation, and I repeat that the best way of doing so is to avoid them altogether by early lifting. Early kinds have been in the store-shed for some time, and the seed placed upon the seed trays; second early kinds, such as Yorkshire Hero, are also lifted, and by the time this is in print I hope to be taking up the Victorias, and so once more preserve early, intermediate, and late kinds safe and sound, untainted by blight, and unspoilt from second growth.—EDWARD LUCKHURST.

HARDY ANNUALS FOR SPRING BEDDING.

No doubt many of your readers find a source of great interest in the articles that appear from time to time on spring flowers, and doubtless there are many, especially among the numerous class of amateurs, who read those articles with deep longing, and imagine that spring bedding is a luxury only to be enjoyed by those who can keep professional gardeners and have unlimited means at their disposal; for how often do we meet with gardens, tastefully and elaborately decorated with the usual summer occupants of the flower garden, which are left bare and unsightly till such time as these can be placed in position?

Very much has been written in commendation of hardy annuals as spring bedders, and for effectiveness, cheapness, and easy management they are unsurpassed for this purpose. Early in last September I commenced the laying-out of a flower garden, and, not caring to have this garden barren till the middle of June, I some time previous began to consider for means of making a spring display. Not being in possession of any of the plants so much used for this purpose, such as *Pansies*, *Aubrietias*, *Daisies*, *Polyanthus*, &c., and not having the means wherewith to obtain large quantities of bulbs, I was compelled to fall back upon annuals, and to trust to them to bring about the effect I was desirous of obtaining. I am happy to say they have not betrayed my trust, but produced as fine and effective a display of colour as one could desire to see.

But what in my estimation renders these plants so recommendable is the small amount of expense and labour or skill required for their production and maintenance. Any piece of ground that may chance to be at liberty about the end of August will be suitable for raising them. My method is to

sow the seeds thinly over a good space, and allow the plants to remain where sown till removed to the flower garden. On the appearance of the seedlings, should they be too thick, thinning is resorted to, allowing the plants sufficient space to develop themselves. By this means thousands of sturdy plants are obtained at a minimum cost of time and labour. The plants are removed to the flower garden at the latter part of October or beginning of November, choosing mild open weather for the operation.

The varieties I find most useful and reliable for spring bedding are *Silene pendula rubra* and *alba*, *S. compacta rubra* and *alba*, *Myosotis dissitiflora*, *M. sylvatica*, *Limnanthes Douglasi*, white and crimson *Candytuft*, *Nemophila insignis*, *Saponaria calabrica* and *alba*, and *Collinsia bicolor*. In addition to the above I secure a few plants of *Pyrethrum aureum*, which should be sown about midsummer in a cool situation. There are many others that are doubtless good, but I have found the above succeed best with me, and quite sufficient for my purpose. The following are some of the most effective arrangements:—

For large beds—1, Centre *Myosotis*, band of *Limnanthes Douglasi*, edge *Silene compacta rubra*. 2, Centre *Silene pendula rubra*, a band of *Nemophila insignis*, edge *Saponaria alba*. 3, Centre *Silene pendula alba*, band of *Saponaria calabrica*, edge *Nemophila insignis*, which will require slightly pegging-down. For smaller beds either of the taller *Silenes* edged with *Nemophila* will make an effective bed, also *Saponaria calabrica* or *Silene compacta* edged with *Pyrethrum* have a good effect. The *Nemophila* will also make a pleasing bed edged with *Pyrethrum* or white *Saponaria*. These annuals also make most effective ribbon borders either for spring or summer, and from their slight cost and easy culture are within the reach of all lovers of a garden.—A. E., *Heanton Satchville*.

ROYAL HORTICULTURAL SOCIETY.

AUGUST 7TH.

FRUIT COMMITTEE.—Rev. M. J. Berkeley in the chair. Mr. J. Ollerhead, The Gardens, Wimbledon House, sent an excellent Queen Pine weighing about 6 lbs., to which a cultural commendation was unanimously awarded. Mr. R. Gilbert, The Gardens, Burghley, Stamford, sent a seedling Melon, the result of a cross between Hero of Bath and Cox's Improved, but it was too far gone. Mr. J. Thomas, The Gardens, Brockham Park, sent a seedling Green-fleshed Melon, but it was not thought worthy of commendation. Messrs. Rivers & Son, Sawbridgeworth, Herts, sent a dish of Hale's Early Peach from a cold house. The fruit were large and of fairly good flavour. It was considered to be the best of the early Peaches, and on this account a first-class award was voted to it. A dish of Pine-Apple Nectarine was sent by the same exhibitor. The fruit was large and flavour first-rate. A cultural commendation was awarded to it. Nectarine Advance, a new variety, was also sent, but the fruit were small and the quality inferior. A collection of Cherries was also sent by Messrs. Rivers. Early Rivers was excellent, of the Black Circassian type; Black Bigarreau was not good; Bigarreau Napoleon, large and of good flavour, an excellent sort; Bigarreau Noir de Schmidt, an excellent Black Cherry; Bedford Prolific, a form of Black Tartarian, but as shown was of poor flavour; Bohemian Black Bigarreau is an excellent variety well worthy of extended culture; Monstrueuse de Mezel, a good Cherry of the Bigarreau type, of the largest size, but the flavour was not first-rate; Bigarreau Gros Cœur is of a similar character and considered worthy of commendation.

The Welbeck Seedling Nectarine was sent by Mr. Tillery of The Gardens, Welbeck; as shown the fruit did not seem to be different from Elruge. An excellent dish of the Grosse Mignonne Peach was also sent. A cultural commendation was awarded to Mr. Tillery. A dish of Peaches and one of Nectarines were sent by Mr. H. Pressley, gardener to G. Jennings, Esq., Nightingale Lane, Clapham Common. A cultural commendation was awarded. Mr. Lane, gardener to Major-General Fytche, Pyrgo Park, Romford, sent a dish of Barrington Peaches, to which a letter of thanks was presented. Mr. J. Douglas, gardener to F. Whitbourn, Esq., Loxford Hall, was awarded a cultural commendation for excellent Strawberries, also Kerry Pippin Apples from the orchard house. The former were very highly coloured. A dish of Chasselas Hâtif de Tonneins White Grape was sent from Chiswick, and was recommended by the Committee as the best out-of-doors Grape. A new Black Currant was sent by Messrs. Carter & Co. of High Holborn. The Committee requested to see it again in September, as it was recommended for its late-hanging properties.

Mr. Thomas Miles, gardener to Lord Carington, Wycombe Abbey Gardens, sent some splendid examples of Tomatoes, a variety named Stamfordian. It was thought to be a good se-

lection of Hathaway's Excelsior. Mr. Hunter, Lambton Castle, sent a dish of a new Fig, but the Committee decided that it was not different from Brunswick, although they did not doubt its being a seedling. H. M. Dunnett, Esq., of Messrs. Carter & Co., sent a brace of Cucumbers, to which a cultural commendation was awarded. Mr. G. Cooling, nurseryman, Bath, sent seedling Potatoes, but the Committee did not comment upon them.

FLORAL COMMITTEE.—W. B. Kellock, Esq., in the chair. Amongst the more prominent of the exhibits on this occasion were two magnificent plants of *Odontoglossum vexillarium* from Sir Trevor Laurence, Bart., Burford Lodge, Dorking. *O. vexillarium* roseum had six spikes and fifty-four richly coloured flowers of great size and substance. The foliage also was in exuberant health, being deep in colour and leathery in texture. *O. vexillarium*, the old form of this fine Orchid, had eight spikes and upwards of seventy flowers; a cultural commendation was awarded, and a medal was also recommended to be given. Sir Trevor Laurence also sent *Epidendrum nemorale* and *Eulophia guineensis*. The *Eulophia* resembles somewhat a large *Calanthe* in growth, with a robust spike 2½ feet high, having about twenty rosy crimson flowers with triangular-shaped lips. A first-class certificate was awarded for this plant. The condition of the plants exhibited by Sir Trevor Laurence reflected much credit on his grower Mr. Spyers.

Messrs. John Laing & Co., Stanstead Park Nursery, exhibited thirty plants of perennial Phloxes in 8-inch pots. The dwarfness, freshness, and vigour of these plants, with their varied colours and delightful perfume, render them valuable for conservatory decoration, and it is a little surprising that Phloxes are not more generally grown for that purpose. The plants exhibited were extremely fine, and a cultural commendation was worthily awarded for them.

Mr. J. Puttick, florist, Acton, exhibited a collection of Balsams. The plants were dwarf, well branched, and in excellent condition, and the flowers were perfectly double and very fine; the colours were scarlet and white, many of the flowers being attractively marbled. A vote of thanks was awarded.

Mr. B. S. Williams, Holloway, sent a small collection of stove plants, to two of which, *Dracena Bausei* and *Dendrobium suavisimum*, first-class certificates were awarded. The *Dendrobe* resembles *D. chrysotoxum* with a dark centre; and the *Dracena* is one of the most richly coloured of any in cultivation, every leaf being broadly margined with crimson.

Mr. Cannell, The Nurseries, Swanley, exhibited *Pelargonium echinatum*, a fine old Cape species, valuable for winter blooming; also *P. echinatum* Spotted Gem, the flowers being purplish rose with dark blotches on the petals, the centre of each petal being white. A first-class certificate was awarded for this chaste gem. Mr. Cannell also exhibited *Antirrhinums* and *Pentstemons*.

Hybrid *Begonia* Defiance, a brilliant-coloured dwarf variety, but deficient in substance, was sent by Mr. Chambers, Westlake Nursery; also a salmon variety named Safrano, also *Streptocarpus Rhexi* and the elegant Fern *Asplenium viviparum*. Messrs. T. Sander & Co., St. Albans, sent a basket of their Tom Thumb *Candytuft*, which is extremely dwarf and floriferous. *Celosia cristata variegata* (Messrs. Vilmorin et Cie., Paris) was exhibited, but is more curious than beautiful; also a collection of Stocks and double *Pelargoniums*. These came from the gardens at Chiswick, as did Major Clarke's beautiful *Begonia* Moonlight, Mr. Laing's fine *Fuchsia* Earl of Beaconsfield, and some *Abutilons*.

Messrs. James Carter & Co. exhibited out blooms of two varieties of *Dianthus* Heddewigii named *Crimson Gem* and *Eastern Queen*. The size, substance, and richness of the flowers were remarkable. These varieties will be valuable for garden decoration, especially as they have been proved after some years of trial to come quite true from seed.

Messrs. G. Paul & Son, The Old Nurseries, Cheshunt, exhibited a very fine and extensive collection of cut Roses, for which a cultural commendation was awarded; also a new Rose, *Marquis of Salisbury*, a very fine Rose, somewhat resembling *Alfred Colomb*, but fuller and finer than that good Rose, which is high praise; it is, however, not quite so bright in colour as *Alfred Colomb*. It received a first-class certificate.

Mr. Parker, Tooting, sent cut sprays of *Asclepias tuberosa*, a hardy North American species with orange flowers, and was awarded a vote of thanks. Messrs. Jackman & Co., Woking, sent dwarf Conifers; Mr. Woodbridge, The Gardens, Syon House, sent flowering sprays of *Tamarix gallica*, a fine seaside plant, and *Ceanothus americanus roseus*; and Mr. Dean very fine African Marigolds.

PARAFFIN OIL AND PLANT VERMIN.

THIS powerful remedy must be used very carefully. I followed the last prescription of one gill of paraffin to three gallons of water, and found that where the Bean plants had accidentally received a double watering the leaves were all killed by it. I have therefore reduced the quantity to a wine-

glass for the same quantity of water, and found that it can then be safely and advantageously used to very many plants for the destruction of vermin of all kinds.—G. O. S.

THE CARNATION AND PICOTEE BLOOM

AT SLOUGH AND CLAPHAM.

At the date of the National Carnation and Picotee Show held at the Royal Aquarium, Westminster, many good flowers were not in bloom, and some that were exhibited required a week longer for the properties of the flowers to be fully developed; I therefore gladly availed myself of an invitation from Mr. Charles Turner of Slough to inspect his collection when at its best, which was a week after the Exhibition. At that time Mr. Turner could have exhibited a very much better lot of blooms than he did at the Show. I had seen the plants about the end of May, and thought they were in better condition than our own at Loxford Hall, and the state of the plants at the time of my visit fully verified the expectations formed at that time that there would be a most magnificent bloom. Besides the largest and most select collection I may safely say in the world of the oldest and most recent named sorts, there are perhaps several hundred pots of unnamed seedlings, and amongst them a few that have been selected for distribution during the ensuing autumn. It is a very difficult matter to select a batch of seedlings in which every flower will be superior to others in the same class which have already been sent out. Indeed, no one who has been accustomed to purchase new flowers expects to find this to be the case. What we have a right to demand is that they are quite distinct from other varieties already in existence, and that they are quite equal to them in those properties recognised amongst florists. I believe a goodly number of the Slough seedlings satisfy these requirements, and some of them are not only distinct but superior to the finest varieties already in existence in the same class.

To do the Carnation and Picotee well the plants must be grown in pots, and the pots should be removed to a glass house where they can be protected from wet, high winds, and bright sunshine. The arrangements at Slough are, as one would expect, perfect in this respect. There are two large houses, one a lean-to against a wall facing south. Running along the front of the house is a platform about 2 feet wide filled with plants, which can be inspected to the best advantage from the path between this platform and the back stage, on which other pots are arranged. This house is well adapted for bringing plants forward for exhibition, but the exhibitor always requires to retard as well as to push flowers on, and for this purpose there is a similar house against the same wall facing north, and at the time of my visit both structures were a perfect blaze of beauty. There were also large numbers of plants in other positions: some out of doors quite unprotected, others were under old frame lights with the air circulating freely underneath night and day. The growers seem to be devoting their energies more to the raising of Picotees than Carnations, which is a misfortune if not a mistake. I noted the following amongst the new flowers—viz.,

Morna (Fellowes).—Heavy red, the white is very pure; flowers large, colour brilliant; there are a few bars on some of the petals.

Horace K. Mayor (Fellowes).—Another heavy red, the colour very brilliant, and white pure. If Mr. Fellowes can raise a flower with an edge like this and without any bar on the white it will be a grand hit.

Rev. J. B. M. Camm (Fellowes), heavy purple, is a large flower with clear white petal edged with broad rich purple.

Isabella (Matthews) is quite a novelty and a very full showy flower, which will be well adapted for the border or home stage, as it is of very free growth; the edges of the petals are bizzarred with maroon and purple.

Estelle (Fellowes).—Light rose edge; the petals are beautifully formed, clear white, with wire edge like Mrs. Allcroft. There is not a spot or bar on the white. The best flower yet raised in this class.

Lady Louisa (Abercrombie).—This is a heavy rose already described, but as seen at Slough it was finer than the blooms exhibited at the Royal Aquarium. Fanciers will recognise the merits of the flower when I say it has a better petal and purer white, with the beautiful distinct rose shade of Niven's Fanny Helen.

All the above are Picotees, and the only Carnation I noted as new and good was a fine crimson bizarre raised at Slough,

named Unexpected. It is a flower of good properties and gained the highest honours in its class at the Royal Aquarium. It is a better flower than Eccentric Jack. I noted many fine older flowers, but it would be waste of space to go into details of them. I will therefore merely give the best in each class for the guidance of those forming collections.

CARNATIONS.—*Scarlet Bizarres*.—Admiral Curzon (Easom), Campanini (Turner), Garibaldi (Heap), Lord Derby (Heap), Lord Lewisham (Bunn), Mars (Hextall), Mercury (Hextall), Sir J. Paxton (Ely), and True Briton (Hepworth). *Crimson Bizarres*.—Albion's Pride (Headly), Eccentric Jack (Wood), Graceless Tom (Wood), John Simonite (Simonite), Lord Milton (Ely), Lord Raglan (Bowers), Marshal Ney (Headly), Rev. G. Rudrick (Reeves), and Rifleman (Wood). *Pink and Purple Bizarres*.—Falconbridge (May), James Taylor (Gibbons), Lord Clifton (Puxley), Purity (Wood), Sarah Payne (Ward), and Satisfaction (Bowers), a new flower with beautifully formed petals; very distinct. *Purple Flakes*.—Dr. Foster (Foster), Earl Stamford (Elliott), Excellent (Hooper), Florence Nightingale (Sealey), Mayor of Nottingham (Taylor), James Douglas (Simonite), Premier (Milwood), Squire Trow (Jackson), True Blue (Taylor). *Scarlet Flakes*.—Africana (Puxley), Annihilator (Jackson), John Bayley (Dodwell), Mars (Puxley), Mr. Battersby (Gibbons), Sportsman (Hedderly), Superb (Ingram), and Clipper (Fletcher). *Rose Flakes*.—Flora's Garland (Brooks), James Merryweather (Wood), John Keet (Whitehead), Lovely Ann (Ely), Mrs. F. Burnaby (Turner), Rose Magnificent (Reeves), Sybil (Holmes), Mary Ann (Fletcher), and Samuel Newman (Hooper).

PICOTEEs.—*Red-edge*.—J. B. Bryant (Ingram), John Smith (Bowers), Leonora (Fellowes), Miss Small (Fellowes), Mrs. Bowers (Bowers), Mrs. Dodwell (Turner), Novelty (Matthews), Mrs. Hornby (Turner), Peeress (Turner), Princess of Wales (Fellowes), William Summers (Simonite), Thomas William (Flowdy). *Purple-edge*.—Alliance (Fellowes), Ann Lord (Lord), Cynthia (Turner), Alice (Lord), Jessie (Turner), Minnie (Lord), Mary (Simonite), Mrs. Little (Hooper), Mrs. Niven (Marris), Mrs. Summers (Simonite), Picco (Jackson), Rival Purple (Hooper), Zerlina (Lord), Sylvia (Simonite), and Prima Donna (Simonite). *Rose and Scarlet-edge*.—Brilliant (Payne), Edith Dombain (Turner), Ethel (Fellowes), Idalia (Fellowes), Estelle (Fellowes), Lady Louisa (Abercrombie), Fanny Helen (Niven), Juliana (Turner), Mrs. Allcroft (Turner), Miss Wood (Wood), and Purity (Payne).

There are many other interesting objects at Slough, which must be reported on at another time. Especially fine were the Chrysanthemums, a new flower for Mr. Turner, but he has taken it up with his usual spirit, and has also hit on a plan which promises to be a great success. There are two or three hundred standards with stems 3 or 4 feet high. About 150 of these have been grafted with four or five distinct varieties on each head, and the grafts have taken remarkably well. These plants are quite a new feature in Chrysanthemum culture, and will have a very remarkable effect.

LARKHALL RISE, CLAPHAM.

The collections of Carnations and Picotees belonging to E. S. Dodwell, Esq., I also visited, and found it in the same condition as that of Mr. Turner's—just a week too late for the show. There were many fine flowers at their best, and the plants were also in splendid condition, showing the care that has been bestowed upon them; and how well they repay the ardent cultivator in our large cities and towns, this and many other collections abundantly testify. Mr. Dodwell's collection is most select as to varieties. Being an excellent judge of what constitutes a first-class flower, and having ample opportunity of becoming acquainted with them when in the hands of the raisers, Mr. Dodwell selects all that he deems worthy of culture, and after he has proved them under his own care, if they do not come up to the florist standard they are rejected. There are, for instance, some flowers which do well in the north but are worthless under our treatment and southern climate. I may mention in Picotees a light red-edged variety named Thos. Jivens (Flowdy); its raiser has taken "premium" with it at Newcastle, but Mr. Dodwell and I have both discarded it. In Carnations Mrs. F. Burnaby is one of the finest rose flakes under a northern sky. Mr. Dodwell I do not think grows it, and with me the colour is so pale that, though I had good blooms of it at the show, I did not venture to place it in the stands or even stage it as a class flower. Guardsman (Turner), is a very showy scarlet bizarre, but it is much better adapted for the border than being placed as an exhibition

flower in the south. We ought to be very careful, then, in condemning any flower merely because it does not happen to do well under our treatment; others may cherish what we reject. Amongst a great number of fine blooms I noted the following:—

Sir Joseph Paxton (Ely).—A noble scarlet bizarre. As seen here the petals are large, broad, and beautifully cupped. It seems to be a different flower from that grown at Loxford under the same name.

Capt. Stott (Jackson).—A very beautifully marked crimson bizarre. The colours of this flower were very bright and the petals well formed. It is a very desirable sort.

Warrior (Slater).—In the same class I noticed as being an indispensable flower both for the home stage and exhibition. It is of the same type as *Capt. Stott*.

Rev. George Rudrick (Reeves), is another crimson bizarre with smooth petals and the colours of the *Jenny Lind* type but brighter. The most showy flower in the collection.

In *Picotees*, *Clara* (Bowers) arrested my attention as being very pretty; the edge seemed to be slightly serrated, an unpardonable offence as a florists' flower, but the colour was very bright white, pure, and a sort no grower should lack.

Cynthia (Lord), is a very pretty light-edged rose; a very refined flower that will be an acquisition in a class rich in first-rate examples.

When looking over this fine collection I could but wish, and have every reason to hope, that the culture of Carnations and *Picotees* will be extended to the owners of villa gardens close to our large cities, for these flowers will flourish where Roses and many other flowers barely exist. We want to see something different from the scarlet *Geraniums*, *Calceolarias*, *Chickweeds*, *Houseleeks*, ribbon borders of Beet and variegated Tobacco plants, Cabbage, Kales, &c. We want sweet and beautiful flowers that can be cut and placed in vases where a few pleasant moments may be spent admiring them and discussing their points.—J. DOUGLAS.

NOTES AND GLEANINGS.

WE have received the schedule of the "GREAT INTERNATIONAL FRUIT SHOW" which is to be held at the Alexandra Palace on September 13th, 14th, and 15th. The schedule is divided into ten divisions, and contains sixty-seven classes; the amount offered in prizes being about £350. For a collection of sixteen sorts of fruits the prizes are £16, £12, and £8. There are also good prizes for collections of twelve sorts of fruits. Pines have three classes, and Grapes twenty. For eight varieties, one bunch of each, the prizes are £8, £6, and £4. There are six classes for three bunches each of six specified varieties, and a similar number of classes for single bunches. Prizes are also provided for the best-flavoured black and white Grapes, bunches to weigh not less than 1 lb. each; also prizes for the heaviest bunch of black and white Grapes. Classes of this nature have brought out mammoth bunches in the north, but in the south the "big" bunches exhibited have been comparatively poor and rarely worth the prizes awarded to them. A class for one bunch of not less than 1 lb. weight, showing the finest bloom and finish, would have been worthy of a place in the schedule. A similar class has brought out splendid Grapes in the north, and will probably do so at Carlisle. As the compilers of the Alexandra schedule have "gone in" so largely for Grapes it is unfortunate that a class of the nature alluded to has not been provided. Hardy kinds of fruit are well provided for, and there are several classes set apart for foreign exhibitors only. For a collection of sixteen varieties of vegetables prizes of £6, £4, and £2 are provided, and similar amounts are offered for a dinner-table so arranged as to show the best means of utilising fruit and flowers in its adornment. Good prizes are provided for cut flowers—*Dahlias*, *Asters*, and *Hollyhocks*; but there is no class for *Gladioli*.

A CORRESPONDENT, in referring to the MARQUIS OF BUTE'S VINEYARD, says that if as much sagacity were exhibited by English as by French cultivators that Grapes would be grown on the sunny slopes of hills in the southern counties. He states that if terraces were formed in favourable positions in England the same as is the case in France, and ordinary cultural care was exercised, that there is no reason that such early Grapes as the Black Cluster and Royal Muscadine should not ripen profitable crops in sheltered localities. He submits that very little, if any, more heat is required to ripen early varieties of Grapes than is required to ripen Tomatoes, which he observes are now grown as field crops in the valley of the

Thames. He remarks that he has seen Grapes ripen in warm valleys in France where the Wheat harvest on the hills is little if any earlier than the harvest in Kent and Sussex.

WE last week alluded to the wholesale manner in which Tomatoes are grown in the London market gardens, and not much less remarkable is the appearance presented by acres of VEGETABLE MARROWS. In Messrs. Bagley's grounds the plants were turned out under handlights about the 22nd of May, the station for each plant being made with a large barrowful of fermenting manure. The plants are about 16 feet apart, and so rapid has been their growth that the ground has been completely covered for some time, and thousands of fine Marrows have been sent to market. The growth is never pruned nor stopped, but rambles at will, and it is surprising how fruitful the plants are. The sort grown is the old cream-coloured Marrow, but is a longer variety than is commonly met with in private gardens. Vegetable Marrows are in great demand by the London public, and they will probably be used to a greater extent than usual this year for preserving for winter consumption, since fruit is so scarce and dear, and Vegetable Marrow jam is much relished by children.

ALLUDING to the article ON MELONS on page 65 "A SOUTHERN GROWER," who was a successful exhibitor of them last year, states that his Melons in frames are not doing so well this year as they did last year. He attributes this to the cold weather during May and the early part of June, which checked the growth of the plants in their early stages; and Melons, he remarks, should not receive any check either by low temperature, excessive pruning, or lack of water. Last year his Melons in frames were the best; this year those in houses are in the most satisfactory condition.

OUR correspondent "A NORTHERN GARDENER" states that in his opinion there is a disease common amongst CUCUMBERS quite distinct from that figured by Mr. Smith. He has seen Cucumbers grow with great luxuriance and with apparently healthy root action, and certainly without any nodosities on the roots, and yet the leaves and shoots become so suddenly and severely affected as to render the crop worthless. He does not think it is caused by mites in the soil, because the extremities of the growths are first and chiefly affected, the lower portions of the plants appearing quite sound and healthy, while in the disease figured by Mr. Smith the lower portion of the plants are the first to afford evidence of the malady that affects them so seriously. Cucumbers, he remarks, are more liable to what he calls the "root disease" when grown in light than in comparatively heavy soil.

ONE of the best annuals for spring decoration is *SILENE PENDULA*. It is perfectly hardy, grows freely, and makes glowing pink beds or lines in April and May. It is alluded to now because the present week is the best time for sowing seed. It should be sown thinly in drills, and the plants be thinned early to 6 inches apart, in order that each plant can become sturdy and hardened by thorough exposure to the air. Frequently the *Silene* is not sown until September, which is too late, the plants not having time to become large enough for covering the ground quickly, and flowering early, strongly, and profusely. The variety *S. p. compacta* should not be overlooked, well-grown plants in 5-inch pots produce a charming effect in the early spring months. This variety is becoming popular in Covent Garden Market, which is good evidence of its merits as a decorative plant.

WE have received from Mr. W. Lovel, Weaverthorpe, York, a little pamphlet detailing "HOW TO GROW STRAWBERRIES WITH SUCCESS." The author states that his object is to give some "plain cultural directions, the result of practical experience," on a subject with which he appears well acquainted. The pamphlet appears at an opportune time, and contains good and reliable advice on the cultivation of this esteemed fruit.

A SHORT time ago Mr. Douglas alluded to the adaptability of *FUCHSIAS* FOR TRAINING ON THE ROOFS OF GREENHOUSES, and he enumerated some varieties suitable for that purpose. One, however, that he did not name, although an old variety, is one of the best for that or any other mode of culture—viz., *Venus de Medici*. This extremely free-flowering and very elegant *Fuchsia* is now in fine condition at Kew, both as trained on the roof of one of the houses and also as a column or slender pyramid reaching to the roof of the temperate house. Many *Fuchsias* are planted in the borders of that house and are nearly 20 feet high, but no variety is more beautiful than

Venus de Medici, its healthy glossy foliage enhancing the effect of the blush sepals and purple corolla.

— We regret to hear that the POTATO DISEASE is very prevalent in some parts of Cornwall, the American sorts being the most severely affected. A resident in the district states that "it is worse than has been known for some years."

— It is not often that a new plant attains popularity so quickly as has been the case with Harrison's new Giant Musk, *MIMULUS MOSCHATUS HARRISONI*. It is already established as a market plant, and will shortly be as common on the flower-barrows in the London streets as are Fuchsias, Heliotropes, and Geraniums. As a window plant, a greenhouse plant, and probably as a bedding plant in cool and rather shaded situations, it is likely to become fashionable. Its flowers are not only conspicuous and attractive, but are produced profusely and continuously, and the fragrance of the plant is nearly if not quite equal to the common Musk—qualities which have established it in popular estimation, and rendered it in a comparatively short period a general favourite.

CLAYTONIA VIRGINICA.

THE Claytonias are hardy herbaceous perennials which were more popular half a century ago than they are now. Old

Fig. 26.—*Claytonia virginica*.

plants are, however, being inquired after again, and we happen to be able to answer the question of a correspondent, "Taro," who asks "what sort of plants the Claytonias are," by publishing a figure of one of the oldest of the species. The genus was named after John Clayton, a collector of plants in Virginia. The plant figured was introduced to this country in 1740; it only grows a few inches high and has pretty white flowers. It succeeds best in a moist soil and a shady situation, and is seldom found except in botanical collections. This species is also known as *C. tuberosa*; the roots are eaten in eastern Siberia.

ANNUALS FOR AUTUMNAL SOWING.—As the season for sowing the above is fast approaching I hope that some of your amateur garden readers and workers will interchange opinions on the best annuals for this purpose. I have found the following

to succeed best:—*Godetia*, most beautiful and lasting; *Virginian Stock*, very early, and lasting in flower much longer than when sown in spring; *Saponaria calabrica*, very good; and *Sweet Alyssum*.—G. O. S.

THE SUCCULENT HOUSE AT KEW.

THIS house, which is represented in the accompanying illustration, is generally acknowledged to be one of the leading features in the Royal Gardens. The structure is 200 feet long and 30 in breadth, affording from one end to the other an unsurpassed view of the most characteristic types of vegetation adapted to flourish in dry regions.

Immediately on entering at the north end we find in flower several of the *Stapelias*, or Carrion-flowers of South Africa. Two of these, *S. primulina* and *S. Sarpedon*, are quite new; the former is not much unlike the flower of a Primrose, and is singular in the genus from being of nearly the same colour. *S. Sarpedon* is a fine flower, nearly 5 inches in diameter; it is vinous purple in colour, with pale cross-bars, and the edges are fringed with fine hairs. *S. angustiloba* has remarkably narrow corolla-lobes. *S. bufonia* is really handsome, and also one of the most easily cultivated. The flower is yellow, wrinkled on the surface, and variously spotted with dull purple. Many others are in bud or flower, and the collection is particularly rich in new and undescribed species.

The new genera, *Decabelone* and *Hoodia*, are both represented, the former by *D. Barklyi* and *D. elegans*. The stems of *D. Barklyi* are indeed pretty, having no equal in any of the allies. The flowers have been compared to Foxglove, which it resembles in shape. It has quite the odour of *Stapelia*, but requires to be sniffed from the depth of its tube. The *Hoodia* just referred to was believed to be *H. Barklyi* until its present blooming, when it fortunately proves to be entirely new. The name has not yet been given. It is similar in habit to *H. Gordonii*; the flowers are of much the same colour, but are distinctly cup-shaped.

Turning to the right, attached to an *Euphorbia* is a specimen of the curious *Tillandsia usneoides*, which flowered a short time ago for the first time in this country. It is the "Old Man's Beard" of the south United States and the West Indies. It has narrow leaves and slender stems, hanging in twining masses from the branches of trees, and is covered all over with white scales, as if bedecked with hoar frost. It is used for packing and other purposes, even inclusive of medicine. The flowers are green and inconspicuous.

Of *Euphorbias* there is an unrivalled collection, including many species yet unnamed. One may be mentioned in particular: the stem is divided by constrictions into short joints, where it then expands into broad wings, bearing enormous spines $1\frac{1}{2}$ or 2 inches long, spreading in all directions. *E. stellaspina* is choice and rare, while *Cereus*-like in shape it is covered with branching spines. *E. resinifera* is most important from an economic point of view. It yields the true euphorbium, a drug used by the ancients, and though now obsolete as an internal remedy twelve cwts. were imported in 1870, perhaps for the composition of a paint used to preserve ship-bottoms, it being said to be in some demand for the purpose. Its collection was described by Dioscorides and Pliny, though until a few years ago the true source was unknown to botanists. Unmistakeable as the *Euphorbias* usually are, they sometimes bear a close resemblance to plants widely distinct. *E. mammillaris* in some of its shoots is extremely like *Echinopsis cereiformis*, and which, allied to *Stapelia*, was sometime ago known as *S. cylindrica*. *Sarcostemma Brunonianum* was found some time ago doing duty for *Euphorbia pendula*, the one yielding a refreshing juice, and the other poisonous. A grand specimen of *E. canariensis* faces the door, spreading its square succulent branches almost to the width of the bed. A nearly allied genus, *Pedilanthus*, is peculiar from the foot-shaped form of the flowers, and *P. tithymaloides* is now in bloom.

Bromelia antiacantha, or *B. scepterum* as it is more often called, is now in striking condition; the lower bracts, a foot long, are flame scarlet, those subtending the flowers are pure white, some with scarlet tips. The inflorescence measures $1\frac{1}{2}$ foot in height; the flowers occur in clusters, and are of an unusual violet purple. The mutual dependence between plants and insects, apart from the subject of fertilisation, is beautifully illustrated by *Acacia spærocephala*, the Bull's-thorn *Acacia*, and a species of ant, both found in Nicaragua. In this *Acacia* the stipules are transformed into immense hollow

thorns, wherein the ant makes its home, and finds food also growing on the same tree. Every leaflet develops at the tip a little body, which apparently has no other use than to serve as food. In return for all this hospitality the ant acts as guard

against enemies, keeping off those insects which would otherwise affect the tree.

The Aloes constitute a genus to which much attention has lately been given, resulting in the discovery of new species

Fig. 27.—THE SUCCULENT HOUSE AT KEW.

under old names, and considerable change in the nomenclature. A plant long known as *A. Salm Dyckiana* proves undescribed, and is now called *A. platylepis*; there is also a variety *lutea*. *Aloe cæsia* var. *elatior* is quite a distinct species, and now to be called *A. drepanophylla*. For several years a beautifully spotted kind has been grown without name in gardens, though

supposed by some to be a form of *A. grandidentata*. This it is not, and will shortly be published as *A. tricolor*. *A. Greeni* is a splendid new form; the leaves are long, curving to the apex with large spines, and light green in colour with bars of pale spots. The first results, we believe, of hybridising Aloes may here be seen. One is exactly intermediate between its parents

A. albocincta and *A. grandidentata*, the same plant being produced by reversing the cross. It may be described as a spotted *albocincta* with large spines. *A. Thraski* is most distinct, the leaves being channelled in the way of *Yucca concava*. *A. dichotoma* was perhaps the rarest of all until the recent distribution of seedlings from Kew. It is one of the branching species, which in Damaraland and Namaqualand forms a large tree. It roots with great difficulty, and an imported specimen appears neither inclined to grow nor die.

Beaucarnea Hookeri is one of the queer examples of Mexican vegetation, and two plants are about to flower. They have immense almost globular boles, from which spring a number of grass-like tufts. The Elephant's-foot (*Testudinaria elephantipes*) is represented by a fine specimen, and the flowering stems form a column reaching to the roof. Its hemispherical trunk is about 2 feet in diameter, and presents a strange appearance by the splitting of the bark into large conical scales.

Next in order come the *Gasterias* and *Haworthias*, both including new species, and the latter in particular with pretty forms, some as it were sprinkled with pearls.

Arundo conspicua at the cool end is a fine object for many months in the year, and though hardy is almost an essential inmate of the conservatory. It is much more elegant than the Pampas Grass. Here are several fine examples of *Dasylium* and *Beaucarnea*, which are among the most stately of greenhouse plants, either with long ribbon-like leaves gracefully curving and drooping to the stem-base, or with rigid spiny and glaucous leaves forming a dense head.

The *Crassulaceae*, commencing at the south end, contribute many showy flowers in their season, and include some of the most attractive and useful of succulent plants. *Crassula cordata* is curious from the multitude of little plantlets growing on the old flower stems. *C. Bolusi* is new and extremely pretty; it is scarcely 2 inches high; the leaves are obspathulate, with numerous pits darker-coloured than the rest of the leaf. *C. nemorosa* is rare and most attractive; the leaves are heart-shaped, very fleshy, and deeply glaucous. The *Rochas* now fall into this genus. *C. pallida* is white-flowered, in the way of *C. perfoliata*. *Cotyledon* and *Echeveria*, including all the noteworthy species, with several hybrids, must here be passed over.

The Cape Groundsels are striking in comparison with other species of *Senecio*. One is precisely like an Ivy with large yellow flowers. *S. articulata* is the well-known Candle-plant. *S. Haworthii* flowers in cultivation with extreme rarity; it has spindle-shaped leaves covered with a dense white cottony felt. *S. chordifolia* is new; it has curved terete leaves longer than others of the section *Kleinia*, to which it belongs. *Othonna crassifolia* in one of the cases forms an elegant groundwork for the several *Echeverias* with glaucous leaves; being of a very pale green it shows them off to advantage.

On this shelf are two highly ornamental plants of *Oldenburgia arbuscula*, doubtless the only examples in cultivation. Their stems are nearly 2 feet in height, growing with extreme slowness; the leaves are a foot long, covered with white hair. It is surprising to many that this belongs to the *Compositae*. With the mention of these unique specimens we are brought to *Dyckia argentea*, a plant still more striking, and the only one in Europe. The leaves are 2 feet long, and recurve on the pot so as to hide it completely; they are set with large spines along the edges, and are covered with silvery scales so as to appear like frosted silver.

Vitis macropus always arrests attention. Widely different as it is in form from the Grape Vine, it is still nearly related. It has an obese succulent trunk with two branches bearing a few heavy leaves. The stems increase with great slowness. The year's growth is nearly all cast off with the leaves, leaving generally less than an inch. The separation is quite natural. *V. cirrhosa* produces stems several feet in length, all to be cast off with the exception of about 2 inches. By a recent observation it is shown that some plants (of which *Castilloa* is a good example) separate their barren branches by an articulation just as a leaf. The fertile branches are cast off in other cases. Those of *Reidia glaucescens* resemble pinnate leaves, and, though bearing flowers, are often seen to fall without suspicion of their real character.

The *Agave* group is without doubt the most imposing in the house. The finer specimens are those of *A. glaucescens*, *A. potatorum*, *A. Hookeri*, *A. Kewensis*, *A. karatto*, and *A. Noackii*, with its several branching stems. Several others might be mentioned in point of size. The collection has

several new additions, and includes the older choice kinds. Almost at all times there are to be found plants in some condition of flower or fruit. *Fourcroya Selloa* and *F. cubensis* are now sending up their quick-growing scapes.

The Cacti, though yet unmentioned, are of the first importance. With the exception of about two species all are native of the New World. Many are grotesque to a striking degree, often with flowers of the most brilliant colour. Among the prettiest of the *Mammillarias* are *M. Schiediana*, *M. candens*, *M. nivea*, and *M. minima*. Of *Echinocactus* we may draw attention to the new *E. cylindraceus*. It has very long spines of red colour, and is quite fierce in appearance. *E. viridescens* is also new and distinct. Of *E. Pfeifferi*, *E. Stainesii*, and some others there are very fine specimens. *Echinopsis* also contains many fine representatives. The Turk's-cap is now in bloom; its flowers are pink, and come from between a mass of spines and thick hair forming the cap or inflorescence. It is said that the fruit is sometimes ejected to a considerable distance in consequence of pressure from the spines and hair.

Leuchtenbergia principis is about to flower, and is anomalous in bearing its flowers on the mammæ, which perhaps submits to the same explanation as of those cases where the peduncle in *Erythrochiton* and *Helwingia* is united with the stalk and midrib of the leaf. *Rhipsalis Cassytha* is covered with berries like Mistletoe; the stems are round and long.

A large space is devoted to the gigantic species of *Cereus*, and to the Prickly Pears or *Opuntias*. Of *Opuntia decumana* there is a large specimen, the flat stems of which excite general notice. *Cereus Jamacaru* planted in the ground has grown with immense strength. It has deep-angled stems of glaucous blue appearance. We may briefly allude to *C. multangularis* and *C. Tweediei*. The first is rare and densely covered with short spines so as scarcely to admit the point of a pencil.

On the rafters are many interesting plants. A leafy Cactus, *Pereskia Bleo*, is bearing its large pink flowers. Further on are fine specimens of *Cereus Macdonaldii*, *C. triangularis*, and other night-blooming species. *Aloe ciliaris* suits well as a climber, and has very brightly coloured flowers.

While having mentioned the most important and interesting of the plants, there are many others deserving of notice. Several of the Cacti, the species of *Asparagus*, the Grass-gum trees, frutescent *Sempervivums*, *Rhynchoptalum montanum*, a rare *Lobeliad* with tall perennial stem, and many others, are deserving of the visitor's attention.

NATIONAL CARNATION AND PICOTEE SOCIETY.

THE northern Show was held again this year in the Botanical Gardens, Stretford, Manchester, on Saturday, Monday, and Tuesday, August 4th, 6th, and 7th, in conjunction with the Cottagers' Flower Show held this year for the first time. It was not expected that a good show could be held at so early a date; none of the growers were quite at their best, and some of them were not able to exhibit, notably Mr. Robert Lord of Todmorden and others in that district; another grower whose flowers were not in condition is Mr. Thomas Bowers, Bradford, Yorkshire, a celebrated raiser of new sorts and a most ardent cultivator. Notwithstanding the many drawbacks the Society has had to contend with this year, about three hundred blooms were exhibited fresh and in good colour. I noticed last year that some of the exhibitors had but the calyx round in order to let the outer petals fall back and thus enlarge the flower, and I have been told that some exhibitors have even added a sound calyx from another flower in place of one that has been split. Of course none of the principal growers would stoop to such practices, and the first rule of the Society provides for the disqualification of any stand that has mutilated flowers. It reads thus: "Any stand containing a mutilated flower—i.e., one with a false pod, petals clipped smooth, or calyx clipped, will be disqualified." Rule 5 says: "Flowers having self petals or bizarre petals in flakes, or inserted petals, will be disqualified."

I am indebted to Richard Gorton, Esq., of Gildabrook, Eccles, for the following notes of the Show and list of awards. The principal prizes went to Mr. Benjamin Simonite, Rough Bank, Sheffield, who showed some grand flowers, especially in purple flake and crimson bizarre Carnations. Mr. George Rudd of Bradford, Yorkshire, also exhibited some excellent stands; his scarlet bizarre Carnations, notably Sir J. Paxton, were in splendid colour. In Class A, twelve Carnations all dissimilar, Mr. Simonite was first; Mr. J. Booth, Failsforth, Manchester, second; and Mr. S. Brown of Birmingham third. In the winning stand Dr. Foster (Foster), p. f.; John Keet (Whitehead), r. f.; James Merryweather, r. f.; and Sportsman, s. f., were the best flowers. Mr. Booth had Admiral Curzon and Sportsman very fine. In the next class Mr. Simonite was again first, Mr. Brown

second. Mrs. Allcroft, Mrs. Niven, Miss Sewell, and one or two seedlings were fine. Class C, twelve Carnations, not less than nine varieties, Mr. George Rudd was first and Mr. R. Gorton, The Woodlands, Eccles, second. In Mr. Rudd's stand the blooms of Sir J. Paxton were marvellous examples of size and quality; Admiral Curzon, Mars, Clipper, and Marshal Ney were very fine. In Mr. Gorton's stand the best flowers were Christigalla, r.f.; Sybil, r.f.; Eccentric Jack, c.b.; and Dr. Foster, p.f. A third prize was awarded to Mr. Brown, and fourth to Mr. Thomas Mellor. Class D is a corresponding class for Picotees, and here Mr. Rudd was again an easy first, his best blooms being Zerlina, Alliance, J. B. Bryant, Mary, and Fairy Queen, the latter a light-edged rose of good quality. Mr. Brown was second, and Mr. T. Mellor third. In Class E, six distinct Carnations, and limited to growers of 120 pairs, Mr. Stack of Chesterfield was first, and Mr. Taylor of Middleton second. Class F is a corresponding class for Picotees, and here the first honours went to S. Cooper, Esq., of Timperley, Cheshire; Mr. Taylor of Middleton being second and Mr. Slack third. In Mr. Cooper's stand Ann Lord and Mary were good blooms.

We come now to the classes for single blooms, where Mr. Simonite was again champion; he won first, second, fourth, and fifth in scarlet bizzarres with Dreadnought, Seedling, Mars, and Admiral Curzon; Mr. Booth was third with Admiral Curzon. In crimson bizzarres Mr. Simonite won all the five prizes with J. D. Hextall, to one of which the blue ribbon of the Exhibition was awarded, and a grand specimen it was, full of petal, colour, and quality. In scarlet flakes Mr. Rudd was first with Sportsman, second with Clipper; Mr. Simonite third with a seedling, and Mr. Booth fourth and fifth with Sportsman. In rose flakes Mr. Booth was first with Sybil, the remaining prizes going to good blooms of James Merryweather and John Keet. In purple flakes Mr. Simonite gained all the prizes, the winning blooms being placed in the order of their names—Dr. Foster, James Douglas, Mayor of Nottingham, James Douglas, and Squire Meynell.

In light red Picotees Mr. Simonite was first, second, fourth, and fifth with his own seedlings, Mr. Cooper third. The first-prize flower in this class was of excellent quality. In the heavy red class Mr. Booth was first with J. B. Bryant, and Mr. Gorton second with Miss Small. In light purple edges the first prize went to a seedling, the remaining five prizes going to Mr. Cooper for fine blooms of Ann Lord. In heavy purples the three first prizes went to Mr. Chadwick, Ashton-under-Lyne, for blooms of an unnamed seedling, the three last prizes to Mr. Booth for Picco. Heavy rose-edged was a poor class. Mr. Chadwick was first and Mr. Booth second with Mrs. Lord, Mr. Gorton third with Juliana. In light rose Mr. Simonite was first with a fine variety of his own raising, named Teresa; this was also selected as the premier flower in the Exhibition. The other varieties that gained prizes in this class being Miss Wood and Miss Sewell.

Mr. Simonite had made a mark in the floral world at many previous exhibitions, but I question whether he ever stood so high as he has done on this occasion. He may not only be proud of showing the premium Carnation and Picotee, but the flowers were both his own seedlings; and if his flowers had been at their best, even better varieties would have been shown, especially in the crimson bizarre class of Carnations, and light red Picotees. In the former Samuel Barlow, John Simonite, and Frank Simonite are all advances on existing varieties. In the latter his Mrs. Simonite is a model of what a Picotee ought to be; it is a red-edged Mary with pure white petal. Mrs. F. D. Horner and Mrs. R. Gorton are also fine light-edged reds worthy of a place in the best collections. It was a misfortune that Mr. Lord's flowers were not in, as some of his seedlings not yet distributed are of high-class quality. I question if there are any flowers in the heavy rose class to be placed before Miss Horner; and his Mrs. Dodwell, rose-flake Carnation, is a most refined flower.—J. DOUGLAS.

PAINTING.

WHAT can be more annoying than, after being at the expense of constructing and painting a fine large glass house, to find the whole of the internal paint covered with a black fungus? This has been my case, and to remedy this evil I made the following experiments. Five years since I had an orchard house painted with a thin kind of creosote, at a temperature of 180° or thereabouts. In a month after this painting I painted a door of this house with only one coat of paint (oil and white lead). This coat still looks well and there is not a particle of mildew or fungus to be seen on it. Since that time I have carried out the same mode to some considerable extent, and nothing can look better. The creosote gives a good smooth body, it destroys all germs of fungus, and at half the expense of labour and material. Many persons are now adopting my plan. The creosote to be used costs 5d. per gallon; it is not the common sort, but that used for steeping timber without

being heated. I always heat it, as it penetrates the wood much better and dries more rapidly. I can strongly recommend this mode of painting for any kind of work.—OBSERVER.

EXPERIMENTS ON THE FLOW OF THE SAP.

[Read at the Scientific Committee of the Royal Horticultural Society.]

(Continued from page 71.)

THE system of vegetable physiology now in credence was built upon the faith of the existence of a circulation of the sap, and everything has by degrees been arranged to fit neatly into it. I think I have shown to be rotten Sachs' theory, and in removing it, without having any other props to put in its place, down must come the hypothesis that the plant derives all its carbon from carbonic acid in the atmosphere, or its nitrogen from free uncombined nitrogen through the leaves, and, of course, all power of taking anything into the system through the leaves, and all hypotheses of feeding, whether vegetarian or carnivorous, through these organs. These theories of circulation by imbibition, diastasis, endosmosis and exosmosis, I regard as already defunct. Six weeks' unavailing effort to get the slightest indication of any of these phenomena in the living plant seem enough for me. The current is steadily upward, and not only permits nothing to come down against it, but is too powerful to permit anything to deviate from its own place and force its way into another, even by uniting with it on the way upwards. I say, therefore, that for a plant to absorb carbonic acid whether free or combined through the leaves for the purpose of supplying it with that important element involves a physical impossibility, and yet this is one of the best-received vegetable physiological hypotheses. It has the advantage of giving a glimmer of an explanation how plants may have first originated. They consist of carbon, nitrogen, and mineral ingredients, besides oxygen, which may be derived from the latter. It is open, then, to say that plants derive their mineral constituents from the degradation of rocks, and their carbon and nitrogen from the atmosphere—and some plants (as Lichens) may. But when we come to test the hypothesis by common sense and experience they tell us all that you may try to grow a plant in mineral ingredients and leave it to get its carbon from the atmosphere as much as you like, but it won't grow. As far as common people can see it will only thrive in humus, in other words where its roots can draw carbon from the organic matters already elaborated in the soil by the long-continued accumulation of past ages. But Sachs states it very broadly. "The fact is unquestionable," says he, "partly established by direct researches on vegetation, partly inferred from the circumstances under which many plants live in a natural condition, that most plants which contain chlorophyll—e.g., our cereal crops, Beans, Tobacco, Sunflower, many saxicolous Lichens, Algae, and other water plants obtain" (through the leaves—he does not say so here, but it is implied, and is of the essence of his theory) "the entire quantity of their carbon by the decomposition of atmospheric carbon dioxide, and require for their nutrition no other compound of carbon from without."—(Sachs' "Text Book" (*Dyer's Trans.*), p. 620.)

Now in the first place one of the principal of the circumstances to which he certainly above alludes must be the influence of light on assimilation, his interpretation of which I have endeavoured to refute. Next I may mention another phenomenon which seems to me equally adverse to his views—viz., that the plants of which we are speaking exhale oxygen during the day, and carbon during the night. If carbon in whatever form passes up from the root to the leaves during the day, and a chemical decomposition takes place whereby it or other ingredients are altered in their way, oxygen must be liberated, and after being carried on with the stream of sap will be set free when it reaches the leaves, while the carbon will be used up in the plant; and this is just what takes place by day. But at night, when no feeding or assimilation is going on, no chemical action takes place either, but the carbonic acid with which the sap is charged escapes through the thin cuticle of the leaf, as from an uncovered vessel, without any interchange of oxygen at all.

As to the experiments referred to by Professor Sachs, I believe the principal one was made by De Saussure about the beginning of this century (1805), but unhappily I have been unable to see the paper containing it. I know no recent experiments with carbon. As recorded, Saussure's experiment proved that plants in sunlight increase in their amounts of carbon, hydrogen, and oxygen at the expense of carbonic acid and water. But there is no indication whether he attempted to determine whether the carbon was taken up by the leaves or the roots; and as that was not what he was trying to find out, I am disposed to infer that no precautions were taken to decide that point. He seems to have been very careful in measuring the contents and constituents of the air, the plant, and the earth; but as it is plain from that very fact that they were all three subjected to the same experiment at the same time, I do not imagine that the experiment could touch our point.

It must not be inferred that I dispute altogether the possibility of the air supplying a portion of its carbon to the plant. Carbonic acid may be carried down into the earth by showers, and there put in a fit condition for the plant which may then take it up by the roots. All that I say is, that it does not enter free into the plant through the leaves, and that the idea of its descending from them, and supplying the plant with carbon for its structure, is an absolute impossibility.

With a glance at one other class of experiments which bear on this point I have done. I do not know that Sachs has relied on it, but other physiologists have. It has been maintained that not only carbonic acid, but nitrogen free and uncombined, is taken up by the plant through its leaves, and it is plain that if the one can be so taken up there seems no very good reason why the other should not also—possibly not so readily, but still taken up. Both are constituent gaseous elements found in the plant, and if it could obtain one of them through the leaves it should follow that it might equally well have obtained the other also. Now with nitrogen the question has been fairly tried by many first-rate chemists and physiologists, and a great multitude of experiments have been made; and although discrepancies have occurred on points which do not concern this question, I think I may say that, with one exception (De Villa), the conclusion has been unanimous in the negative. It would be tedious to mention all the experimenters, but when I name Boussingault as commencing the inquiry, and Lawes and Gilbert terminating it, no question as to the efficiency of the inquiry can arise. Mr. Lawes' concluding words were, "In view of the evidence afforded of the non-assimilation of free nitrogen by plants under the wide range of circumstances provided in the experiments, it is desirable that the several actual or possible sources of combined nitrogen to plants should be more fully investigated both quantitatively and qualitatively."—ANDREW MURRAY.

MR. RICHARD WEBB.

On Thursday, July 26th, at his residence, Culham House, Reading, died Richard Webb, Esq., of Calcot, aged 79. Seven years have passed since we visited this worthy and consistent gentleman at his country residence, and these were our notes upon him and his surroundings:—

We were introduced to ten dogs, and then to sixteen cats, fathers and mothers of fourteen kittens, all alive and not doomed to a brick-and-water death. "Their master must be a kindly man," and so we found him—a lover of animal and vegetable life too—a man who does firmly what he thinks has to be done rightly, and the evidence was before us. There was a stone monument bearing this inscription—

"Beneath this stone lies buried
Our race's deadliest foe;
Myriads he has hurried
Down to the realms of woe.
"More mischief he produces
Than filled Pandora's box,
And more disease induces
Than plagues'd th' Egyptian flocks.
"Evils attend his reign,
Yet thousands own his sway,
And madly hug the chain
That drags their souls away.
"Reader! beware his wiles,
He lurks within the bowl,
And stabs you while he smiles,
Then oh! shun ALCOHOL."

The burial took place more than forty years since, and there were on the occasion committed to their grave three hogsheds of strong beer, two casks of home-made wine, and some dozens of foreign wine and spirits. After the ceremony a harvest-home supper was provided on the lawn under a tent, when nearly 150 persons sat down to a good substantial meal consisting of a roast sheep, two rounds of beef, barley puddings, and a copper of coffee, after which they listened to a good temperance lecture, and then returned home free from any intoxication. There has not been a drop of alcoholic drink allowed in the house or on the premises since, not even for medicinal purposes, nor has the deed ever been repented of, but, on the contrary, rejoiced over.

Calcot includes ten acres, entirely enclosed with a brick wall about 8 feet high, hollow, and with mock chimneys at uniform intervals, justifying a popular comment, "He may well have good crops of fruit, for he warms the walls!" It is especially devoted to fruit-growing, and trees—Pears, Apples, and Plums—all most healthy, and free from disease and moss, are there mostly at judicious distances; but the underwood (for the term is justified by the abundance) is composed of Nut bushes. These are not bearers of common kinds, but of more than thirteen varieties raised by Mr. Webb and shown by him at

the Great Exhibition of 1862. We tasted specimens of their fruit, Cobs as well as Filberts, and, late as the season is, they were all good, but we especially liked those called Eugénie and Garibaldi.

The Nut bushes are never pruned, but they are of an uniform height of about 10 feet. Last year they produced nearly eight tons of Nuts.

Lastly we will note an extraordinary Black Hamburgh Vine. Its stem is 2 feet 3 inches in circumference at the ground's surface; it has eight branches.

No. 1 is about 51 feet long, with laterals	9 feet long.
No. 2 is about 24	10 feet long.
No. 3 is about 24	7 feet long.
No. 4 is about 41	7 feet long.
No. 5 is about 62	In a greenhouse.
No. 6 is about 80	In a greenhouse.
No. 7 is about 80	7 feet long.
No. 8 is about 25	7 feet long.

Thus this Vine covers 1539 feet of wall, without including any part of the roof of the greenhouse which it clothes, nor various portions of branches, which, having taken root, are not to be considered as sustained by one stem—they are rooted layers, but unsevered from the parent. The two largest Vines mentioned by Speechley, are one growing about a century since at Northallerton in Yorkshire, and the other at Bury St. Edmunds. The first covered 1320 square feet, and the second 1233.

MOSS ROSES FOR MARKET.

At every turning in the neighbourhood of Covent Garden we find huge piles, baskets, and bunches of Roses. In whatever way fashion may vary as to flowers in our gardens, there is always a large demand for Moss Roses in London. The white, though not very common, and two or three reds, and a pink one are the kinds principally supplied; and the old Provence Roses, too, are among the most beautiful. The common Moss, a sport from the old Cabbage Rose of our cottage gardens, is not largely cultivated by market growers, the reason being that it is not considered either robust or floriferous enough to give remunerative results. The sort most preferred is a deep red kind, which, though not nearly so mossy as the lighter-coloured varieties, is remarkably floriferous, and the buds being cut before they are too much expanded their mossy surrounding is more noticeable, and consequently the blooms are more valuable. To supply the enormous demand for Moss Roses some market growers near London devote several acres of land to their culture. The plants are, however, seldom grown on one spot, but are distributed about in rows or patches—some occupying a warm border sheltered from the north winds by a wall, hedge, or row of fruit trees, whilst others occupy positions right under orchard trees, the main crop being generally grown on an open quarter. By this arrangement a lengthened season of cutting is secured. The border plants furnish the earliest blooms; these are followed by those under trees; and those in the open quarters give a later supply. As regards culture, the plants are cultivated much after the fashion adopted for Raspberries, with the exception that the old wood of the Roses is allowed to bear several crops before it is cut away, whilst in the case of Raspberries the wood is removed every year. When well established, Moss Roses are so productive of young growths from their bases that it is found necessary to keep the bushes well cleared of both the old wood and the weakest of the young growths. The plants themselves are grown on their own roots, and probably under these conditions much better results are obtained than would be the case were any form of budding or grafting on other stocks practised.

As an under crop Moss Roses are most profitable. They thrive well under orchard trees, and the shelter afforded by the overhanging boughs often saves the buds from frost in the spring, when those in open quarters often suffer severely. The usual mode of increasing the plants is to lift the old shoots, strip them of the outside growths, which are planted in rows 3 feet apart each way. During the first two years after planting vegetable and salad crops are grown between the rows; but the third season, if the Roses do well, they require all the room. As before stated, during the winter the old shoots, as well as the weakest of the young shoots, are thinned out and the most robust are shortened back. The soil between the rows is then forked over, and a heavy mulching of half-rotted manure is applied. Thus treated the plants receive no further attention until the spring, when the blooms are fit for gathering. Some growers plant Moss Roses between Gooseberry and Currant bushes, but it is not a desirable method, as in a very

short time the trees get so crowded that both crops are seriously injured.

Early in June the buds are ready to gather. The plants are gone over each alternate morning, and every bud sufficiently open is cut off; and now the superiority of the red kind above referred to is more than ever apparent. Its buds nearly all open at the same time—that is, all the buds on each truss. This allows of the whole truss being cut at once, which is a great saving of labour, and the produce is of greater value in the market. As they are cut the blooms are laid in large baskets or hampers, which, when full, are placed on waggons and sent to market, where they are rapidly bought up by hawkers and women with baskets, who wire the blooms with a little foliage attached, and sell them for the coat at a penny a-piece. After the plants have done blooming some growers layer the branches on each side of the rows; they are firmly pegged down and covered with soil. In the autumn these will have taken root, when they are lifted and separated from the parent plant, and after being trimmed are used to form new plantations. This is a capital plan, inasmuch as young vigorous plants are easily obtained without severely injuring the existing plantations. Moss Roses and the Poet's Narcissus (*N. poeticus*) are sometimes planted alternately, and the flowers of the latter being all gathered before the Roses come into leaf neither crop is in any way impaired.—W. (in *The Gardener*).

OUR BORDER FLOWERS—BASTARD BALM.

ONE of the least of the families of hardy herbaceous plants, and in all probability it is one of the least known and least cultivated. This cannot arise from their having no attractions. In a botanical point of view they are an interesting family, for it only falls to the lot of a few to have the pleasure of securing specimens of these rare Labiates in their native habitats, but when so seen and secured they are a prize indeed.

They are of dwarf and pleasing habit, and are well adapted for either rockwork, border, or pot. They will bear full exposure, but they are the better for having partial shade afforded them. They require thorough drainage and a good, sound, free loam to develop themselves in. They are increased by division in spring when growth has commenced. Until well established they require care, time, and patience to work up a stock. I have not to the present time been able to increase them from seed.

I only know of three kinds—*Melittis alpina* from Switzerland, of very dwarf habit, adapted for rockwork; very seldom met with. *M. grandiflora* is a charming plant, deserving extensive cultivation. *M. melissophyllum* makes up a trio of no mean order. They are telling plants for exhibition in a collection of herbaceous plants, and cannot fail to repay by their beauty any labour bestowed upon them.—VERITAS.

ARRANGING CUT FLOWERS.

AN article in "St. Nicholas" on the arrangement of flowers contains the following directions which may be read by all who love flowers, and yet have not the knack of arranging them to the best advantage in bouquets or in vases for the table:—

The colour of the vase to be used is of importance. Gaudy reds and blues should never be chosen, for they conflict with the delicate hues of the flowers. Bronze or black vases, dark green, pure white, or silver always produce a good effect, and so does a straw basket; while clear glass, which shows the graceful clasping of the stems, is perhaps prettiest of all.

The shape of the vase is also to be thought of. For the middle of a dinner-table a round bowl is always appropriate, or a tall vase with a saucer-shaped base. Or, if the centre of the table is otherwise occupied, a large conch shell, or shell-shaped dish, may be swung from the chandelier above, and with plenty of Vines and feathering green, made to look very pretty. Delicate flowers, such as Lilies of the Valley and Sweet Peas, should be placed by themselves in slender tapering glasses; Violets should nestle their fragrant purple in some tiny cup, and Pansies be set in groups with no gayer flowers to contradict their soft velvet hues; and—this is a hint for summer—few things are prettier than Balsam blossoms or double variegated Hollyhocks massed on a flat plate, with a fringe of green to hide the edge. No leaves should be interspersed with these; the plate should look like a solid mosaic of splendid colour.

Stiffness and crowding are the two things to be specially

avoided in arranging flowers. What can be uglier than the great tasteless bunches into which the ordinary florist ties his wares, or what more extravagant? A skilful person will untie one of these, and adding green leaves, make the same flowers into half a dozen bouquets, each more attractive than the original. Flowers should be grouped as they grow, with a cloud of light foliage in and about them to set off their forms and colours. Do not forget this.

It is better as a general rule not to put more than one or two sorts of flowers into the same vase. A great bush with Roses, and Camellias, and Carnations, and Feverfew, and Geraniums growing on it all at once would be a frightful thing to behold; just so a monstrous bouquet made up of all these flowers is meaningless and ugly. Certain flowers, such as Heliotrope, Mignonette, and Myrtle mix well with everything; but usually it is better to group flowers with their kind—Roses in one glass, Geraniums in another, and not try to make them agree in companies.

When you do mix flowers be careful not to put colours which clash side by side. Scarlets and pinks spoil each other, so do blues and purples and yellows and mauves. If your vase or dish is a very large one, to hold a great number of flowers, it is a good plan to divide it into thirds or quarters, making each division perfectly harmonious within itself, and then blend the whole with lines of green and white and soft neutral tint. Every group of mixed flowers requires one little touch of yellow to make it vivid; but this must be skilfully applied. It is good practice to experiment with this effect. For instance, arrange a group of maroon, scarlet, and white Geraniums with green leaves, and add a single blossom of gold-coloured *Calceolaria*; you will see at once that the whole bouquet seems to flash out and become more brilliant.

NOTES ON VILLA AND SUBURBAN GARDENING.

IF there is one period of the year more than another when there is some cessation from labour in the garden it is during the month of August. The flowers are then at their brightest, the fruits at their sweetest. It is the harvest of enjoyment, the reward of toil—pleasant health-giving toil in the case of the amateur gardener—the period of repose, brief indeed, but pleasant, and such as all who labour have a right to enjoy. It is a period also for instruction—the time when not only successes can be appreciated, but failures detected and improvements suggested. It is during late summer that the plans for another year should be formed, when the quantities required of different plants—of flowers and vegetables—should be determined on. This cannot be so well effected at any other time. It is those who decide on their plans early who succeed the best; labour and space then become utilised, and waste of either, which is inevitable in the absence of a definite plan of action, is in a great measure avoided.

But in order that a garden may be thoroughly enjoyed neatness must prevail everywhere: there must be no weeds on the walks or the borders. The margins of the beds must be trim, and the lawns must be smooth. The flowers must also be orderly by the removal of decayed parts, and the due use of stakes or pegs to support those which need such assistance. Carnations are now fading—those sweet and beautiful flowers which should be seen in every villa garden in town or country. Some of the best varieties have recently been alluded to in the *Journal*—the high-class florists' varieties; but there are others equally worthy of notice, such as the crimson and white Cloves. Let these be increased. Layering may still be done if it is done promptly: the manner of doing it was lately described in another column. Let any choice Geraniums be increased. There can be no better time for inserting cuttings of these than the present, and no better place than light soil in the open garden. If care is exercised several cuttings may be taken without injuring the plants or beds. When rooted the cuttings can be taken up and potted for preserving through the winter. When the greatest possible numbers of plants require to be wintered in the least possible space cuttings of ordinary decorative kinds should be inserted closely—that is, an inch or two apart, in pots or boxes, there to remain until the spring. The pots must be well drained, and the soil rather sandy and rather firm. The cutting pots or boxes should be placed in a sunny position in the open air. Show Pelargoniums may still be cut down and the cuttings be inserted. Plants which were cut down a fortnight ago will have commenced making fresh growth. When they have grown about half an inch the soil, every particle of it, should be shaken from the roots, and the plants should be firmly potted in small pots.

Plants that are flowering freely, such as Fuchsias, Balsams, Geraniums, &c., will be much benefited by liquid manure. Nothing is better than a little cow, sheep, or horse dung dissolved in water, or failing this, half an ounce of guano, not

more, may be dissolved in a gallon of water and the plants be watered with it twice a-week. Chrysanthemums must be well supported with water. It is only by good attention given to them now that a fine autumn display can be provided.

Small plants of Cinerarias and Primulas must be potted and placed in cool shaded frames, and be kept regularly moist and free from insects. These plants are very valuable for spring decoration. Seed of Calceolarias—the richly-spotted Calceolarias—should be sown now. Drain the pots well, fill them with light sifted soil, water thoroughly, and then sow the seed thinly. A dash of silver sand may be sprinkled over the surface after the seed is sown, and the pots should then be placed in a dark cool frame. If each pot is placed in a saucer containing half an inch of water the soil will be kept moist by absorption, and the seeds will germinate freely: light must then be gradually admitted to the seedlings.

Wall trees and wall plants generally must have their shoots secured, and superfluous growth removed. Nothing is more untidy than disorderly wall trees, and nothing more inimical to future crops of fruit or flowers than overcrowded shoots. These remarks apply with special force to outdoor Vines, which are frequently much injured by permitting the shoots to grow into a wild tangled mass. There are many sunny walls in villa gardens where refreshing Grapes might be produced if the advice given from time to time by Mr. Douglas were strictly carried out.

Kitchen-garden crops must never be overlooked. One of the most important of crops to be provided for now by sowing seed thinly is the crop of Cabbages. If the ground is dry water it well before sowing the seed, and shade it for a few days to assist germination. An excellent small Cabbage is the Cocoon. Carter's Heartwell Marrow is a new sort worth growing, and Enfield Market is one of the best larger sorts. Seed of Cabbage Lettuces may be sown for producing a supply during the early winter months. The Victoria and Hardy Hamersmith are useful sorts. Winter Onions may be sown thinly in drills; the White Tripoli is a serviceable variety, the Giant Rocca often growing thick-necked. The crop of winter Onions is a very useful one, as the bulbs are seldom injured by the grub, which is often so destructive to the spring-sown crops. Remove all decaying Pea haulm, and hoe and rake if needed bare ground, for neatness is a chief element in making a kitchen garden attractive.

DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

HARDY FRUIT GARDEN.

THE Strawberry runners have been cut from the parent plants, and they are very strong, though red spider as usual has gained a footing on the leaves. It will be necessary to dip the leaves in soapy water, which will effectually destroy the pest. We have not yet been able to plant out the runners in the open ground, as we could not get the quarter ready owing to a crop of Peas being on it. We seldom have sufficient rainfall for the plants in autumn, and it is always best to plant in a shallow depression in which to retain the water when applying it from the rose of a water pot. Each plant has also a little loam and rich manure placed round the roots to encourage quick growth. "W. S. P." in last week's Journal has written well on the culture of this fruit. It has always been stated that our soil is a sandy loam, and it is of the greatest importance that information should be supplied from different classes of loam. It is also certain that sorts which do well in light soil are often the reverse in soil of a heavy nature. Our estimate of sorts is rather different from that of "W. S. P." We still retain Black Prince for earliest; next Keens' Seedling, followed by President, James Veitch, Auguste Nicaise, Duc de Magenta, British Queen, Frogmore Late Pine, and Loxford Hall Seedling, a most abundant bearer either for culture in pots or out of doors. It was later by a week than Frogmore Late Pine this year. We had to discard Vicomtesse Héricart de Thury, Sir J. Paxton, Elton, Dr. Hogg, and a sort that is now asked for—Anna de Rothschild. La Constante will not be grown again.

Wall fruit trees still require considerable attention. They should be looked over to see that no branches have been displaced, and any growths that are loose must be nailed in close to the wall. If the shoots are not close to the wall they shade the fruit and also look very untidy. If the fruit of Peaches and Nectarines is shaded by the leaves the foliage ought to be removed, else the fruit will not colour well. A leaf on a fruit will cause a green mark, while the rest of the skin may be red. Fig trees should also be looked to. Some persons prefer allowing the young wood to hang loosely about, but this system does not answer in a well-kept garden. Seldom in large gardens is much wall space devoted to Figs, but where it is the shoots must be laid-in to the wall the same as has been already recommended for other trees. The fruit must also be exposed to a certain extent to the sun to bring out its full flavour. Currants, Cherries, and late Gooseberries should be covered with netting to protect

the fruits from birds. We have gathered a few of the earliest Apples, such as Red Juneating, and Irish Peach is also coming in for use. Cherries from wall trees have been bearing most abundantly. Elton and Bigarrean Napoleon have been quite loaded with fruit. Both the above sorts are well worthy of extended culture; the latter is particularly useful, as the fruit hangs so well after it is ripe.

PINES.

Fruit near the ripening stage should be freely ventilated, and to do this in a place where only a few Pines are grown requires that a compromise must be made with plants in growth. The latter require a rather close moist atmosphere, and the house to be closed early in the afternoon. This treatment will not do for ripening fruit, but when we have any of this description in the house we do not shut the ventilators closely, and we also keep the atmosphere of the house a little drier. As soon as the fruit is out the plants are destroyed, unless there are suckers required from them which are not yet large enough to remove. The suckers will grow at a much more rapid rate if they are left on the parent plant until they are of large size. We do not take off and pot small suckers if we can help it. On the other hand, plants which have fruit formed and swelling require the same treatment as growing plants. It is requisite to pay particular attention to the roots at this season. The plants must on no account suffer for want of water. The young plants intended to fruit next summer should be encouraged to make plenty of roots, so that the pots are fairly well filled with them by the end of August. The treatment required must be regulated by the state of the weather, which so far is very changeable, but do not draw the plants by a too close and moist atmosphere.

Orange and Fig Trees in Pots.—If instructions given in previous numbers have been carried out, the surface dressings will have become matted with roots, and the trees will be in good health and well furnished with ripe or ripening fruit. As soon as the Figs are nearly ripe syringing the trees must be discontinued, but if this has been done well so far, spider will not damage the leaves until all the fruit is gathered. Watering at this time must be done in a careful manner: the trees must not suffer by the want of it, neither must they become water-logged from receiving too much; in the latter case the fruit will be watery and flavourless. When all the fruit has been gathered we remove the trees to a cool house where air and light is freely admitted to them, and enough water only is applied to them to prevent the roots from receiving injury. The Orange trees must be kept in a house with the night temperature about 65° or 70°; they ought to be syringed twice daily with tepid water applied with considerable force. The fruit takes a long time to ripen.

GREENHOUSE AND CONSERVATORY.

We have just turned the stage Pelargoniums out of doors, and after being exposed for a few days the plants will be cut down, cutting the growths back to within two or three eyes of the old wood. The best parts are saved for cuttings, rejecting the long-jointed pithy wood. Small shoots with fresh green leaves strike roots freely. The pots with the cuttings should be placed on a stage or shelf close to the glass. About a day or two after cutting-down the plants the wounds will be dried-up, when water may be applied to the roots. If there is no room for the plants indoors a good plan is to place them in an exposed position out of doors, but this does not answer in wet districts, as an over-supply of water will probably cause "spot" on the leaves. The best place is near the glass in a half-span or span-roofed pit. Air should be freely admitted at this season night and day. When the plants have started into growth, and the shoots are about an inch long, turn the plants out of the pots and shake nearly all the soil from the roots, repotting in pots a size smaller than they had been previously potted in. We have arranged a collection of Lilies and herbaceous Phloxes in the place of the Pelargoniums, and a few plants of the most choice varieties of zonal Pelargoniums, which are excellent decorative subjects, and when well treated they flower very freely, producing their brilliant trusses of bloom until the Chrysanthemums are in bloom.

Cinerarias and Calceolarias require to be grown in low-roofed frames or pits, and unless these are shaded by some object on the south side some slight shading should be thrown over the glass to prevent the sun from acting injuriously on the fleshy leaves. No plants are more liable to be attacked by red spider, and none show the effects of it sooner. Fumigate at once when the pest appears.

A correspondent wishes to know the names of the best varieties of Pinks and Carnations for forcing. It may be useful to other readers to know that there are varieties specially adapted for this purpose. The ordinary florist types would be spoiled if subjected to a high temperature early in the year. Tree or perpetual-flowering Carnations will continue producing flowers all through the winter and spring months in a night temperature of 50° or 55°. Some of the best varieties are Guelder Rose, Rose Perfection, Defiance, Empress of Germany, Gloire de Lyon, King of the Belgians, Prince of Orange (Picotee), Proser-

pine, and White Swan. Clove Carnations require a little forcing to have the flowers in from May onwards. The best are Bride (Hodges), King of Yellows (Abercrombie), Purple Prince, and Sentinel (scarlet); add to these the new variety Mrs. Matthews, forcing Pinks Derby Day, Coccinea, Lady Blanche, Lord Lyons, and Rubens. All the above plants are most useful for the greenhouse in winter and early spring.

FLORIST FLOWERS.

We have now plenty of lateral growth on the Pinks, and shall insert a few more pipings to make up those that have failed. The pipings already rooted will be planted in fine soil out of doors, or perhaps in boxes, as we do not require a large quantity and the boxes are convenient. We have still some fine flowers on the Pink beds from late growths. We have very nearly finished layering the Carnations and Picotees; the plants having been grown under glass, they were placed out of doors for a few days before laying down the growths. An amateur called at Loxford the other day and said layering was a mystery to him. He was quite delighted to see how easy the operation was performed. We remove the surface soil of the pots and add some fresh light soil, into which the young rootlets enter freely.

Those who have not yet potted their Auriculas should lose no time in doing so. When at Slough the last week in July I found they were making preparation to report their whole collection. Ours were potted in May, but many small offsets which have grown too much for their pots will now be shifted into others of a larger size.—J. DOUGLAS.

TO CORRESPONDENTS.

* * All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

MR. ADDISON, Ormiston, Edinburgh, writes to say that he can supply "J. B. J." with the Aquilegias required.

SEEDLING SWEET WILLIAMS (W. C.).—They are very pretty and varied in colour.

EARLY ONIONS (Amateur).—The earliest brown spring Onions which are sent to Covent Garden are grown from transplanted bulbs. Seed is sown very thickly in May in rather poor soil. The plants are not thinned, and they form small bulbs by the end of July. They are then pulled up and dried, and are planted in drills very early in the spring. The bulbs when planted are about the size of hazel nuts. Several acres of Onions are thus grown in the London market gardens, and the crop is a lucrative one.

EXHIBITING DWARF FERNS (G. S.).—We do not know what is meant by "three British dwarf Ferns, distinct varieties;" but if you have quoted from the schedule correctly, "small-growing varieties of Lastreas, Athyriums, and Polystichums" cannot be disqualified.

DICSONIA ANTARCTICA (C. R.).—It is an exotic Fern.

ARTIFICIAL FERTILISERS.—Will "J. B. K." oblige "PACET" by stating in what proportion the superphosphate, potash, and nitrate are to be mixed, and how applied in the autumn to dwarf Roses on the Manetti, and whether applicable at any other season of the year to those and other outdoor plants?

GRAPES DISEASED (A. C.).—They are severely affected with what gardeners call "the spot," and is caused by the roots being not sufficiently active to supply the demands for the upper growth. Removing the soil from above the roots, replacing it by some richer compost, and covering the surface at night and during heavy rain with mulch, and uncovering during sunshine, usually removes the malady. If the roots have descended into wet or ungenial subsoil they must be brought to the surface in the autumn.

DRIED HORSE DROPPINGS FOR MUSHROOM BED (St. Edmund).—The droppings would probably heat were you to sprinkle them lightly with water, better the drainings of a dunghill. If you could add some fresh droppings so much the better, mixing with the old after sprinkling the latter with water or liquid manure. In a week or so after making-up the bed you will be able to ascertain whether the materials are any good or not, by their heating or otherwise. All that is wanted is a gentle heat of about 75°, and if that be secured the material is little inferior if any to fresh; indeed, we have had some good beds formed of similar material.

CREOSOTE FOR NETS (G. O. S.).—"We obtain our creosote from Churchill and Williams, Tonbridge Wells, but it can be obtained in any large town, bearing in mind it must be the thin creosote. We merely draw the net through it, the excess being strained off by pressure. We also use the cloth of which the hop pockets are made, 5d. per square yard. This when creosoted lasts many years, and is very good for protecting wall-fruit trees. The protection by means of paper is an idea of Mr. Bréhauf. When used in the way I stated in the Journal it forms a very efficient and economical protection for various kinds of spring vegetables. The net should be so formed as to allow the meshes to lie parallel to one another when stretched out.—OBSERVER."

GATHERING EVERLASTING FLOWERS (Mrs. T.).—If you gather the flowers before they are fully expanded they will not break off in the manner of which you complain.

PRUNING TEA ROSES (A Constant Subscriber).—They should be pruned in spring when the buds are swelling, early in April being a good time.

LILIUM LANCIFOLIUM (Idem).—We have bulbs producing more than twelve flowers. We have grown them for several years, the newly-formed bulbs becoming larger annually. They ought not to be kept quite dry at any time; the soil should be perceptibly moist even during the winter.

CARNATIONS AND PICOTEEES FOR EXHIBITION (P. Tulse Hill).—You will find in another column a selection by Mr. Douglas of the best varieties in their respective classes

TROPEOLUM SPECIOSUM (M. P.).—It is a hardy and very beautiful climber, and produces a brilliant effect on walls in Scotland. It does not appear to be easy to establish in England, but Mr. G. F. Wilson has exhibited flowering sprays from his garden at Weybridge. A cool moist situation should be selected for the plant in England; in Scotland it appears to flourish in any aspect.

ABNORMAL GROWTH OF POTATO (E. C.).—It is unusual for tubers to form in the axils of the leaves, and generally results from some check having been received in the early stages of growth. We have seen similar instances of aerial tubers. Last year a Potato was exhibited at South Kensington which had been grafted on the Tomato, and tubers much larger than the one you have sent to us formed freely in the axils of the leaves.

MARÉCHAL NIÉL ROSE UNHEALTHY (L. M. N.).—The leaf sent suggests that it does not receive sufficient nourishment. Remove the surface soil and replace with manure, apply also liquid manure during dry weather.

SEEDLING PETUNIA (J. Hood).—The specimen sent is one of the finest of its colour we have seen, and is well worthy of being cultivated as a named variety. The fringe is not peculiar, as it is found in other varieties of continental origin.

WEED IN MEADOW (G. S. D.).—It is the Rest-harrow or Cammock (Ononis arvensis). Can any of our readers inform us how it can be cheaply exterminated?

INSECTS ON ROSES AND PELARGONIUMS (J. B. B.).—The foliage has been much infested with aphid and is now mildewed. Remove the worst leaves, and sponge and syringe the remainder with soft-soap water or a solution of Gishurst compound, made by dissolving 2 ozs. of either soft soap or Gishurst in a gallon of water. Remove the shanked Grapes as soon as you can perceive they are affected. There is no advantage in breaking off the shoots of your wall trees; cutting is quite as effectual and more neat.

CATERPILLAR ON AMERICAN WILLOW.—The insect sent has nothing to do with the Potato, nor is it ever known under the name of the "Potato dog" (a name unknown to collectors). It is the caterpillar of the common puss moth (Cecura vimula), and is not likely to be injurious to plants.—I. O. W.

NAMES OF PLANTS (St. Vincent).—Spiraea sorbifolia. (John Davies).—Hedge Mustard (Sisymbrium officinale). (J. R.).—Specimen insufficient, perhaps an Eucalyptus. (J. Shearer).—1, Cuckoo-flower (Cardamine pratensis); 2, Wood Crane's-bill (Geranium sylvaticum); 3, Red Rattle (Pedicularis palustris); 4, Cotton Grass (Eriophorum angustifolium). (E. Pickard).—Leycesteria formosa; specimen insufficient. (J. Dunlop).—The Marvel of Peru (Mircibilia Jalapa). (J. H.).—1, Gnathosia sp.; 2, Calaminta grandiflora; 3, Nepeta angustifolia; 4, Helichrysum arenarium. (J. A.).—Sisyrinchium striatum. (A. H. S.).—Stanhopea zebrina. (A Suffolk Subscriber).—Catalpa syriensis. (Devonian).—1, A variety of Polystichum aculeatum; 2, It is an Acrostichum, but the specimen is insufficient.

POULTRY, BEE, AND PIGEON CHRONICLE.

GREAT HORTON SHOW OF POULTRY, &c.

THE eighth annual Show was held at Great Horton on the 4th inst. This was by far the best ever held by the Society, the entries being good in every department, the poultry and Pigeons being unusually well represented. Turner's pens were used in the open air, and the weather was fine and hot.

Game headed the list, some of the best birds of the day being shown, but many otherwise good were very bad in moult. *Spanish, Cocksins*, and *Brahmas* were not numerous but uncommonly good, and the *Hamburghs* also a very choice lot. In *Bantams* the Variety class showed up in finest plumage. Most of the *Game*, though good, were quite out of feather. Of *Rabbits* with three classes there were some grand animals, notably in the Variety class, where several extra prizes were awarded. First a Dutch, second Silver-Gray, extra second an Angora, third Silver Fawn, and extra third Belgian Hare.

Pigeons a capital entry, and the classes generally good. Pouters were—first a Blue cock, second Red, and third a Blue. Carriers, first a Dun, an easy winner in a good class; second and third Blacks. In *Dragoons* the winners were good but the rest poor. English Owls were a really good lot and mostly Blues. Turbits, first and second Blue, and third Yellow. In *Short-faced Tumblers*, first and cup for the best in all classes a capital Almond hen, second Almond cock, and third Yellow Mottle. Antwerps produced a good entry, and there was, as may be thought, keen competition, the young class proving specially good. In the Variety class first was a White African Owl, second Magpie, and third Fairy Swallow.

POULTRY.—*GAME*.—*Brown Red*.—Cock.—1, W. & A. Fenwick. 2, W. Rudd. *Black Red*.—Cock.—1, W. Rudd. 2, J. C. Dixon. *White*.—J. Waddington. *Any other variety*.—Cock.—1, H. Walton. 2, W. Rudd. *Hen*.—1, R. Walker. 2, W. Rudd. *Black or Brown Red*.—Hen.—1, W. Scholefield. 2, A. S. Sugden. *Chickens*.—1, H. Walton. 2, E. Lund. *SPANISH*.—*Black*.—1, J. Thresh. 2, J. Powell. *COCHIN-CHINA*.—1, R. P. Percival. 2, C. Sedgwick. *BRAMA*.—*Pootra*.—1, H. Beldon. 2, J. Rawnsley. *White*.—W. Scholefield. *ANY OTHER VARIETY*.—*Game*.—Hamburgh and Game. *Chickens*.—1, J. Powell. 2, C. Sedgwick. *White*.—H. A. Barclay. R. P. Percival. *HAMBURGH*.—*Silver-spangled*.—1, H. Beldon. 2, Fawcett & Anderson. *Silver-pencilled*.—1, H. Beldon. 2, J. Rawnsley. *Golden-spangled*.—1, J. Rawnsley. 2, H. Beldon. *Golden-pencilled*.—1, H. Beldon. 2, J. Rawnsley. *Black*.—1, C. Sedgwick. 2, Hobson & Robinson. *Chickens*.—1, C. Sedgwick. 2, J. Sharp. *POLANDS*.—1 and *White*.—H. Beldon. 2, J. Rawnsley. *ANY OTHER VARIETY*.—1, G. Furness. 2, H. Beldon. *BANTAMS*.—*Game*.—Hamburgh and Game. *Chickens*.—Cock.—1, J. Blamires. 2, W. F. Entwistle. *Chickens*.—1, W. F. Entwistle. 2, E. Walton. *Any other variety*.—1, E. Walton. 2, J. F. Crowther. *DUCKS*.—*Aylesbury*.—1, J. Newton. 2, R. Craven. *Rouen*.—1, J. Newton. 2, H. Hanson. *Any other variety*.—1, H. Beldon. 2, J. R. Pollard.

PIGEONS.—*POUTERS*.—*Cock or Hen*.—1, J. E. Crofts. 2 and 3, E. Horner. *CARRIERS*.—*Cock or Hen*.—1, E. Yardley. 2, E. Horner. 3, Mrs. Belk. *White*.—J. E. Crofts. *J. Tomlinson*. *DRAGOONS*.—*Cock or Hen*.—1, E. Woods. 2, J. Booth. 3, E. Horner. *White*.—J. E. Crofts. *English*.—*Cock or Hen*.—1 and 2, Ward & Rhodes. 3, E. Woods. *White*.—J. Thresh (2). *TURBITS*.—*Cock or Hen*.—

1 and 3, R. Woods. 2, E. Horner. **TUMBLERS.**—*Short-faced.*—Cup, 1, and 2, H. Yardley. 3, E. Mawson. *Long-faced.*—1, J. Thresh. 2, A. Smith. 3, R. Woods. *vhc.* E. Horner. **BARBS.**—*Cock or Hen.*—1 and 2, Mrs. Belk. 3, H. Yardley. **ANY OTHER VARIETY.**—*Long-faced.*—Cock—1 and 3, S. Wade. 2, B. Rawnsley. *Hen.*—1, B. Rawnsley. 2, S. Wade. 3, J. Cockett. *Short-faced.*—Cock—1, W. F. Entwistle. 2, H. Yardley. 3, A. Brook. *Hen.*—1, W. F. Entwistle. 2, H. Yardley. 3, T. Bottomley. *Medium-faced.*—Cock—1, S. Wade. 2, W. F. Entwistle. 3, B. Rawnsley. *Hen.*—1 and 2, W. F. Entwistle. 3, S. Wade. **CHICKENS.**—1 and *vhc.* W. F. Entwistle. 2, S. Wade. 3, B. Rawnsley. **ANY OTHER VARIETY.**—*Cock or Hen.*—1 and *vhc.* Ward & Rhodes. 2, E. Horner. 3, J. E. Croft.

RABBITS.—*LOP-EARED.*—*Buck or Doe.*—1, H. Woods. 2, R. Murgatroyd. **HIMALAYAN.**—*Buck or Doe.*—1, J. Robertson. 2, J. Mills. *vhc.* H. Woods. **ANY OTHER VARIETY.**—1, E. Pepper. 2, J. S. Swithenbank. 3, Buckley. 3, E. Robinson. 3, J. Robertson. 3, S. Swithenbank. 3, Buckley.

JUDGES.—Mr. T. J. Charlton, Blenheim, Manningham, and Mr. E. Hutton, Pudsey.

GLAMORGANSHIRE POULTRY SHOW.

THIS Show was held at Aberdare on the 2nd inst. A good prize list with great provision in pens, marquees, and attendance only brought about one hundred entries, no doubt because the Show is little known and badly advertised. **Dorkings** were very good. First Grey, second White. *Brahmas* good, but *Game* out of feather, and *Spanish* very good and well shown. In cockerel and pullet first were grand Dark Grey Dorkings, second Brahmas, and third Buff Cochins, three pens equal to holding their own at any show. *Hamburgs* were very good but not numerous. *Polish.*—First Silver, second Gold, and both good. *French* were very good. In *Bantams* Blacks were first, Scotch Greys second, and Silver Sebrights third. *Ducks* and *Geese* were, as usual, very good here.

POULTRY.—**DORKINGS.**—*Grey or Coloured.*—1, Miss M. Leyshon. 2 and 3, H. Feast. **BRAMA** FOOTRA—1, E. Lawrence. 2, S. W. Thomas. 3, H. Feast. **GAME.**—1, E. Winwood. 2, R. Pearson. 3, The Powell Duffryn Coal Co. **SPANISH.**—1, J. Kitchen. 2, H. Feast. **COCHIN-CHINA.**—1 and 3, E. Clatworthy. 2, H. Perkins. **CHICKENS.**—1 and *vhc.* M. Leyshon. 2, E. Lloyd. 3, E. Clatworthy. **HAMBURGERS.**—*Gold-pencilled and Spangled.*—1, J. Carr. 2, J. Rosier. *vhc.* H. Feast. *Silver-pencilled and Spangled.*—1 and 2, H. Feast. **POLANDS.**—1 and 2, E. Feast. *vhc.* E. Lloyd. **BOUDANS.**—1 and 2, S. W. Thomas. **CREVES.**—1 and *vhc.* H. Feast. 3, E. Lloyd. **BANTAMS.**—1, T. E. Phelps. 2, S. Hosgood. 3 and *vhc.* Morris & Cameron. **ANY OTHER DISTINCT BREED.**—1 and 2, H. Feast. 3, O. Burford. **DUCKS.**—*Aylesbury.*—1, H. Feast. 2, E. Lloyd. *Rouen.*—1, Miss C. Leyshon. 2, J. Moody. *vhc.* H. Feast. **GEES.**—1, J. Thomas. 2, Miss Harrys. **TURKEYS.**—1, Miss Harrys. **SELLING CLASS.**—*Pouls.*—1 and 3, H. Feast. 2, D. Lewis. *Ducks.*—1, Miss C. Leyshon. 2, W. Wheeler. 3 and *vhc.* H. Feast.

JUDGE.—Mr. E. Hutton.

RYHOPE SHOW OF POULTRY, &c.

THIS Show took place on the 6th inst., and was a pretty good one as regards the quality of the exhibits. *Dorkings* did not muster well, but the *Cochins* were really grand, not alone in size but also in quality of plumage. In *Brahmas* first were Dark and second Light, but the rest were poor. *Spanish* a grand lot. *Polish* were moderate, but the *Game* good throughout. The single cocks were placed—first Brown Red, second Black Red, and third Piles, and Brown Reds won in pairs. There were some good chickens. *Hamburgs* were as good as any section of the Show, the winners such as will be difficult to beat. *Bantams*, always an important section here, were good, but not as numerous as we have seen them. In Reds were some good birds; the first Black and second Brown Red, and in the following class Duckwings were first and Piles second, the latter out of feather. *Ducks* a good section, but the birds mostly out of feather. Ornamental Ducks, first and second Pintails, and third Carolinas.

POULTRY.—**DORKINGS.**—1, J. White. **CHICKENS.**—2, T. & R. Miller. **COCHINS.**—*Buff and Cinnamon.*—1, 2, and 3, G. H. Procter. **CHICKENS.**—1, G. H. Procter. 2, W. Jaggs. *Any other variety.*—1, H. A. Clark. **BRAMA** FOOTRA—1, R. Shield. 2, J. Maughan. 3, J. N. Lawson. **CHICKENS.**—1, J. Gargett. 2, R. Sewell. **SPANISH.**—1, T. Newlands. 2, R. Shield. 3, G. F. Kellett. *vhc.* W. Jaggs. **CHICKENS.**—1, J. D. Booth. 2, R. Shield. **POLISH.**—1, R. Sewell. 2, H. A. Clark. 3, J. Gargett. **CHICKENS.**—1 and 2, G. Elliott. **MALAYS.**—1, J. Nelson. 2, G. Carter. 3, Holmes & Destner. **ANY VARIETY.**—Cock—1, J. A. Nelson. 2, G. Carter. 3, G. Alderson. **CHICKENS.**—1, W. Bearpark. 2, I. H. Todd. *Any other variety.*—1, Holmes & Destner. 2, W. Allan. 3, G. Carter. **HAMBURGERS.**—*Golden-spangled.*—1, R. Keenleyside. 2 and 3, Holmes & Destner. **CHICKENS.**—1, R. Keenleyside. *Silver-spangled.*—1, J. G. Walker. 2 and *vhc.* Holmes & Destner. 3, G. Alderson. **CHICKENS.**—1, W. Bearpark. **Golden-pencilled.**—1, T. & G. Kidson. 2 and 3, J. G. Walker. **CHICKENS.**—1 and 2, T. & G. Kidson. *Silver-pencilled.*—1, D. Clow. **CHICKENS.**—2, D. Clow. **ANY OTHER VARIETY.**—1, F. H. Steriocker. 2, T. M. Derry. 3, J. D. Booth. **CHICKENS.**—1, T. W. Richardson. 2, Harrison & Christison. **GAME BANTAMS.**—*Black-breasted and other Reds.*—1, J. A. Nelson. 2, T. & R. Miller. 3, J. Miller. **CHICKENS.**—1, J. A. Nelson. *Any variety except Game.*—1, J. Sanderson. 2, J. Patison. 3, G. Alderson. **CHICKENS.**—1 and 2, G. Elliott. 3, J. Peacock. **DUCKS.**—*Aylesbury.*—1, F. E. Gibson. 2, J. Johnson. 3, Mrs. Walker. *Rouen.*—1, J. A. Nelson. 2 and 3, J. Dixon. *Aylesbury or Rouen.*—*Ducklings.*—1, Mrs. Walker. 2, G. Searth. *Any other variety.*—1 and *vhc.* Rev. J. G. Milner. 2 and 3, J. Johnson. **SELLING CLASS.**—1, J. N. Lawson. 2, J. Young. 3, D. Clow. *vhc.* J. Patison. **BARNDOOR FOWLS.**—1, J. F. Hedley. 2, J. Bowman. **ANY DISTINCT VARIETY.**—1, G. Richey. 2, D. Roberts.

RABBITS.—*LOP-EARED.*—1 and 2, J. Handell. *Any other variety.*—1, E. Pepper. 2, J. W. & O. Moses. 3, S. Potts. *vhc.* W. Harcastle.

JUDGE.—Mr. E. Hutton, Pudsey.

COMMON RABBITS.

WHERE mere amusement, the table, or profit is the object sought common Rabbits are most satisfactory. They will bear great exposure to cold, and thrive well on almost any kind of

food. Too much moist or succulent food, as cabbage leaves or vegetables generally, is not proper for them any more than for the fancy varieties, for it is likely to disorder the bowels and render them too relaxed, particularly if young; bran, oatmeal, oats, or split peas should be mixed with them, and a little new or fresh hay given occasionally. The fancy varieties, on the contrary, must be kept warmer; the atmosphere of the place in which they are kept should never be less than temperate or they will degenerate. Wet or damp is particularly injurious to them, and they must be carefully protected from all chills and draughts.

Common Rabbits exhibit a variety of colours. Of these the brown, the grey, the black, and the black-and-white are in some respects to be preferred. The white with pink or red eyes are rarely good mothers, and are certainly the most tender in constitution.

In selecting Rabbits for breeding be careful to choose those of the largest and strongest build and from the most healthy stock. The doe should not be less than seven months old and the buck eight or nine months. A grey or brown doe and a black-and-white buck, or the buck grey or brown and the doe black-and-white, generally produce the finest progeny; at any rate do not pair a buck and doe of a similar colour or from the same or similar stock. In-and-in-breeding, as it is termed—that is, from the same stock or parentage, never succeeds, and where it is repeated every fresh brood becomes weaker and weaker. The greater strangers the buck and doe are to each other the better and stronger will their progeny be. A few days before a doe is ready to kindle you may see her nibbling the hay or straw and pulling the down from her breast to make a soft warm bed for her expected young. As soon as you observe this, or rather a week before you have reason to look for the young brood, take care to supply her with a little soft fresh hay or cut straw to make her bed with; brushed straw well rubbed together with the hands until no longer brittle is very good for this purpose.

In a day or two after the doe has kindled take the opportunity when she is feeding to look at her brood and examine if they all appear fairly formed and healthy. Do this quickly and carefully, as some does are jealous of their young being interfered with, and will forsake them if she observes them to have been touched or moved. If she keeps so much in her sleeping place as to give you no opportunity to inspect them, endeavour to entice her out by giving her some fresh favourite food, as a cabbage leaf, the top of carrots, or the like, or take her out of the hutch. If you find too many in the nest (more than four if good Rabbits or six of the common kind), and one or more of that number appear weak or puny, take it or them away, and the remainder will be all the better for it, as too numerous a litter will weaken the mother and prove too many for her to support. If you happen to have another doe with a smaller number of young about the same time, you may put the little thing among her brood, and she is very likely to suckle and bring it up.

When the doe has kindled give her a small slice of bread soaked in warm milk, but with no more milk than the bread absorbs, once or twice a-day. When suckling her young the doe should be well supplied with succulent nutritious food—cabbage leaves, nuts, thistles, lettuce, green corn, dandelions, a little parsley, or the tops of carrots are very good at this time. A little barley meal mixed up with warm milk or water, fresh brewers' grains, or bruised malt made into a warm mash should be given occasionally, but not too much at a time, as it sours and is then injurious. Morning and early in the evening are the best times to feed her, and then take care that she has plenty, for a doe while suckling requires at least twice as much food as when she has but herself to feed. So soon as her young begin to feed be sure to supply them with as much as they can eat at least three times a-day.

When about ten or twelve weeks old the young if strong and healthy will not require to be suckled any longer by the doe, and should be removed to another hutch and kept by themselves. By the time they reach the age of four or five months they must be separated, particularly the bucks from the does, for they are quarrelsome little animals and rarely agree as they approach maturity. Never allow the young to be put in a hutch with a buck, as he will worry them terribly and even kill them. Be sure also to keep them free from rats and other vermin, or the little helpless creatures will soon become victims.

In not less than a week or two after the young are removed from the doe she may be allowed to take the buck again, unless it be too near the end of the old or early in the new year, when the cold is too severe for the young brood, in which case breeding should be postponed until milder weather sets in. The fancy varieties should not be permitted to breed more than three times in the year, or it will exhaust strength, so that the young will be weak and unlikely to live. After the third year has passed the best thing you can do with either buck or doe is to feed and fatten it for the table. Common Rabbits may be a year older if strong and healthy.

If a buck is kept a single hutch—that is, one with but one compartment, with wired door and feeding trough, will do well to keep him in. A similar hutch if of sufficient size, say not less than 2 feet in length, will do to put the young progeny in when taken from the doe; but they must not remain together after four or five months old, indeed as soon as you observe them beginning to fight they must be separated and kept apart.

Rabbits naturally feed on vegetables, and readily eat most of the edible productions of the field or garden. Meadow grass cut green, milk thistles, carrot tops, cabbage leaves, clover, tares, hare parsley, stalks and leaves of chicory, leaves of white beet, parsnips, new hay, and Jerusalem artichokes are all good for them, and may be given occasionally to vary their food. Too much green vegetable food must not be given them, as it is too apt to relax their bowels, but should be served out to them with or after their dry corn food, and at all times must be a day or two old.—(*The Pet Stock Bulletin*.)

CANARY BREEDING.

THE breeding season is fast drawing to a close, and birds, both old and young, will soon be in heavy moult; in fact the young from early nests are already pushing forth their new and more showy plumage. There is not much advantage gained in prolonging the breeding of Canaries beyond the end of July, owing to the old birds becoming sick and weakly and the young from such not thriving so well as those hatched in the months of April, May, and June. Already many breeders have cleared away all nesting materials, pulled down the breeding partitions, and cleansed and appropriated the same for moulting or preparing the most promising young for the coming season's exhibitions. Some breeders have sets of partitions or cages specially set apart for moulting their birds, keeping one or two birds in each compartment; and others will moult several broods together in some corner of a room or snug recluse, the birds being kept in a state of semi-darkness to prevent them from pulling each other's feathers during the moult. I consider it quite as essential to cleanse the breeding places and cages at the end of the breeding season as it is when putting-up the birds to breed, for if there should be any vermin lurking about it is not possible that the birds can remain undisturbed during roosting. And this is a matter much to be regarded whilst birds are moulting, for it prevents or at least checks the birds (which become uneasy and fretful through the vermin) from pecking their quill feathers at a time when they are charged with blood, the starting of which hinders the free growth of the feathers, and not only retards the maturity and unfolding of the same but weakens the birds.

Respecting the remarks upon Canaries and their eggs alluded to in page 339, No. 840, Mr. Hervieux further states:—

"Thunder is another accident, for when there happens any extraordinary thunder on the seventh or eighth day after the hen has been sitting the little ones which are scarce half-formed sometimes perish, and the eggs that were thought to be good because they were dark and somewhat heavy are quite spoiled by the thunder. When the thunder happens in the daytime and the hen is gone off the eggs to ease herself or feed, there is much cause to fear the eggs will be spoiled, and therefore you must then endeavour to make the hen return to her nest, for when on them she commonly saves them from that accident, and therefore the thunder is not to be so much dreaded at night, because the hen is then on her eggs.

"Some put a bit of iron into the nest to hinder the effect of the thunder, but I will not prescribe that as a sovereign remedy. When the thunder happens on the eleventh or twelfth day the hen has been sitting it is not so much to be feared, because the little ones are stronger, though still in the shell, and very often it only makes them hatch twenty-four hours before their usual time.

"Thunder sometimes is so violent that it destroys both old and young, and if they are ever so little out of order otherwise, that thunder makes an end of them, and they are found dead and stiff in their huts, without any other cause.

"The eggs are generally thirteen times twenty-four hours under the hen—for instance, you place five or six eggs under your hen on a Saturday at seven in the morning, and you will have young hatched the second Friday following in the morning. Some, but very rarely, hatch one day before the usual time: either the thunder or the great heats, as in July and August, may cause them to advance; others, on the contrary, come twenty-four hours later or thereabouts, and that is occasioned by cold, as sometimes happens at the first sitting in April; or it may proceed from having handled the eggs too often, as has been said; or lastly, the hens being sickly or weakly may hatch a day or more later than usual.

"The fear of breaking the eggs when handled makes us take them up trembling, and even so we often break them, either pressing them too hard between the fingers, or else letting them fall for want of holding them fast. To obviate this accident, which daily happens to the most experienced persons, they are not to be handled unless in case of necessity, and when you

cannot avoid it. You must take them up unconcerned and without dread, for the fear of breaking them often proves a dangerous precaution. If, therefore, you boldly take up your eggs in your fingers by the ends, but never by the middle, as I observed before, you will be sure not to break them; and if still you be apprehensive notwithstanding all these precautions, you may make use of a small thin spoon to take them up with, and that way you will still be safer."

Even with the foregoing precautions of Mr. Hervieux (which are worth observing), still accidents may and will otherwise occur to eggs through overgrown nails puncturing the shells, or through the claws being clogged with dirt gathered from the cage bottom, which will frequently cause the egg-shell to become indented. The former obstacle may be obviated by carefully cutting the hens' claws (the nails) before they commence sitting; and the latter may be prevented with the cage bottom being kept scrupulously clean and well supplied with grit sand and an occasional bath. But the trimming of the nails will only be necessary when the hens are above one year old.—GEORGE J. BARNESBY.

LARGE HIVES.

DURING last winter I bought "A Handy Book on Bees," by Mr. Pettigrew, and having read it I determined to try his system of large hives, of course for honey or profit, but more especially to break down the prejudices of the bee-keepers in this district (Northumberland), where small hives only are used. I ordered some hives from Manchester 18 inches in diameter and 12 inches deep inside measure. I bought three stocks in small hives from an old man and set up my apiary, determined to succeed; but when I had the first swarm on June 14th and put it into the large hive I was laughed at by an old bee-keeper who assisted me to hive the swarm, and who assured me it was no use, the bees would never fill it, for he had had fifty years' experience, and 4 stones was the greatest weight of honey he ever had.

On the 22nd I had another swarm, and on the 27th I had the third, both of which I put into large hives. I also had two second swarms, which I put into small hives. The third hive did not swarm a second time, for the floorboard had a feeding trough in it, and the bees filled it with comb, and I simply lifted the hive off the board, and with it came the comb out of the trough. I had by me ready another board with a large hole in it, under which I placed an 18-inch eke. I lowered the comb through the board into the eke, and the latter is now nearly full of comb. But as I wish more particularly to speak of the large hives I will not at present say more on the second swarms or stocks, but if you think it worth while to insert this I will write again after the moor season is over.

To return to the hive of June 14th. It was full of comb and honey in five weeks, but the board and hive only weighed 34 lbs. That of the 22nd is also quite full; that of the 27th is not yet full, but quite three-fourths, and it is a 20-inch hive, which was sent by mistake. These facts in the face of the worst season for many years proves that Mr. Pettigrew's system is very good, and those who have not read his little book should do so at once.

I will send my bees to the heather on the 1st of August, and if it is a good season hope to get 100 lbs. of honey from each hive. It is a sight to see the bees at work. The doors are 3½ inches wide, and the stream in fine weather is nearly constant, and often I think the bees are swarming. I should like to know the best plan of getting bees out of supers, and I would further inquire why it is that there are often, say, from ten to twenty bees on the ground, evidently dying, in front of the hives. Are they robbers "come to grief," or workers having lived their natural term, "shuffling off this mortal coil?"—HARDY OF THE HILLS, Northumberland.

DRIVING BEES.

I HAVE read with much pleasure the two articles from my brother amateurs on bee-management in your Journal of June 21st, page 474, and July 5th, page 24; and although I have not been quite so far in my experiments as Mr. Kendal, yet my little experience may be helpful to some young beginners.

First I would say it is from your Journal that I have gained most of my experience or information. Until I read your pages, like many others I thought the sulphur pit must be the doom of our little friends, and I hated such a barbarous practice and did not care to keep them; but when I saw they could be managed in a more humane way I resolved to make a beginning.

Last September I bought one swarm in a very small skep, for which I gave 15s. I fed them a little in the autumn, and they stood the winter very well. I commenced feeding them again about the middle of April, and continued feeding until swarming time. The quantity of syrup I gave was from 6 to 8 lbs. I intended swarming them artificially, but they were forwarder than I expected, and on the 30th of May a fine swarm issued naturally, which I hived successfully in a large 18-by-12-inch

Pettigrew hive which I made myself, and they have now almost filled it with comb.

On the 22nd of June I resolved to turn them out, as I did not get a second swarm, but they hung round the flight-board for several days, and I thought they were doing no good. But here arose a difficulty; the hive they were in was so much smaller than the one I wanted to transfer them to. The one they were in was only about 14 by 12 inches, and the one I wanted to put them in was a large Pettigrew hive 18 by 12 inches. At last I thought of a plan. I had one of Mr. Neighbour's super covers, which was just about the size of my stock hive. I then turned the hive bottom upwards, put on the super cover; then I had at hand a round roller towel, which I bound tightly round the junction, and it answered the purpose well. I then commenced knocking the hive with the palms of both hands, and I kept on for about twenty minutes. I then unpinned the towel and lifted up the super cover, when I found all but a dozen or two of the bees had ascended from the combs into the super cover. I then turned up my large hive and poured the bees in like shaking in a natural swarm. I then turned the hive up and placed it on the stand where the old hive stood before, and they took to the new hive well, and the next day they started on at work, and now they have more than half filled the hive with comb. Afterwards I took out the combs from the old hive, broke them up and ran out the honey into a pan, and when I came to weigh it I found I had about 11 lbs., some of which I sold for 1s. and some for 10d. per pound. So I thought, taking all things into consideration, I was very successful; then, if all is well, my hive will be well filled with good clean combs for the winter, and also the bees will be in a good roomy hive, which I think must be much the best.

I may remark that I tried the artificial swarming from one of Neighbour's hives, and I managed to take a very good swarm of bees; but I suppose I was not successful in getting the queen, for they all soon went back, and I did not take them again, and in a few days they came off naturally.

I am now making another 18-by-12-inch Pettigrew hive, which I want to fill with condemned bees if I can get any, and feed them up with sugar syrup. But I wish many others would give us the result of their experience in the autumn feeding as to the feeding apparatus to use and the best way to feed, whether on the top or at the bottom of the hives. No doubt a few hints on these points would be useful to many others as well as myself. I fed at the top of the hive and used a cistern holding three pints of syrup, with a trough 6 inches long, and placed in a box with a hole in the bottom, and stood it on the hive with this hole just opposite the hole in the top of the hive, so that the bees could come up into the box and take the syrup down, and no foreign bees could get near them as the cistern was shut in the box, but they did not take it very fast that way.—J. F.

REMOVING BEES TO THE MOORS.

As it is now time to remove bees to the moors to catch the heather bursting into blossom, it may be well to remind your readers that before removal the hives should be well ventilated and their combs well supported. The closing of the doors of hives prevents natural ventilation, and the disturbance of removal causes commotion, and thereby greater heat inside, hence the cases of suffocation and breakdowns we so often hear about. Suffocations and breakdowns are avoidable. Hives full of bees need much fresh air while on a journey from one place to another. By placing fly-proof wire over the doors and crown holes of hives we let the bees have a current of air through them that prevents overheating and suffocation. Cross sticks to which the combs are attached keep all in their places steady and secure, and thus prevent breakdowns. All hives should be nailed to their boards or well tied down, and sent off in their natural position. To turn hives upside down and send them off bottom upwards is a very foolish and dangerous process, for in this position the dip of the cells is reversed, causing the honey to run out of them more readily. Hives without cross sticks should be turned up two or three days before removal, and have two or three half corks placed between every two combs with a view to keep all steady and firm. If the pieces of cork are properly placed or wedged between the combs the bees fasten the combs to them in less than twenty-four hours, and when thus fastened they are the best possible substitute for cross sticks.

On Saturday last, August 4th, three Manchester gentlemen took their hives to the Glossop moors, and saw their bees at work on the early blossoms of heather as soon as they were let out.—A. PETTIGREW.

OUR LETTER BOX.

BEES.—A correspondent asks if Mr. W. H. Atwood will oblige by stating in what neighbourhood it is possible to obtain bees at 1s. per hive, as mentioned in his letter on page 86, and whether they could be easily transmitted into Worcestershire.

SHIFTING BEES (*Colin Sinclair*).—You can easily drive your bees if you use a similar hive, into which they will better move than into a square box.

As soon as they have gone up and are quiet you can dash them out upon the ground by a sudden blow on the hive top, and if you set the square box near them with one side a little raised they will quickly enter into it. You will have to feed largely and continuously, and it would be better to wait till late in August, when there will probably be but little brood.

HIVE SWARMING WITHOUT DRONES (A.).—It is asked whether "a hive full of combs, but in which the cells are exclusively those of workers and none of drones, can or will send out a swarm." We have no experience to guide us in a case like this, but we should expect to find small drones bred in worker cells, as sometimes happens, in sufficient numbers for the wants of the swarms which might issue. Mr. Ruddle does not seem to have made allowance for the fact that brood does not always develop at the same rate. He is right as to the rule, but in this, as in other cases, there is no rule without an exception. Our correspondent asks why it should have given pleasure to W. H. Atwood to find there were no young bees in his hive which had been driven or had swarmed.

CANARY UNHEALTHY (W.).—It is a natural consequence for birds to fall into moult at about this period of the year, and such no doubt is the case with your birds. Still from the description given your sufferer is affected to a greater extent than birds generally are in the moulting sickness, and may have taken cold. If it is no better give it a warm bath by immersing its feet and stomach in water (blood heat), and afterwards absorbing with a soft cloth, such as a pocket handkerchief, all moisture from the feathers, and gently drying the bird before the fire. In addition to the ordinary food add daily a little bread and milk. In the daytime keep the cage partly covered, and wholly so at night, and out of all draughts. In about a week after the birds have had the bread-and-milk food let them have a little plain biscuit slightly soaked with a few drops of sherry. Discontinue the sugar and replace it with a little piece of salt, and keep a rusty nail in the water.

FOX TERRIER (W. L.).—We know of no special management. Buy "The Dog," written by "INSTONE," and published by Messrs. Cassell.

REMARKS.

- 1st.—A very fine pleasant day, much cooler than yesterday, rather cloudy towards the evening.
- 2nd.—Fine morning, but rather cloudy and stormlike before 11 A.M.; a very pleasant day though showery; one sharp shower for a short time about 4 P.M., afterwards fine and a starlit night.
- 3rd.—Fair but rather cold and dull; rain at 6 P.M., and again in the evening.
- 4th.—Dull in early morning, very fine by noon; fair all day, but at times heavy and stormlike.
- 5th.—Very fine all day; much warmer and more cloudy toward night.
- 6th.—Fine day, but close and stormlike towards evening; rain after 9 P.M., and during the night.
- 7th.—Fine and pleasant till noon, then showery till nearly 9 P.M., after that time starlight.

Mean temperatures during the week very similar to those of the one preceding, but more equable.—G. J. SYMONS.

COVENT GARDEN MARKET.—August 8.

THE bulk of the soft fruit is now to hand, and a good supply of Apples is reaching us. There has been scarcely any alteration in prices since our last report, with the exception of hothouse fruits, all kinds of which are experiencing a considerable fall owing to the finish of the London season; all classes of vegetables have likewise receded in value.

From observations taken near London during forty-three years, the average day temperature of the week is 72.8°; and its night temperature 50.2°.

INARCHING VINES.

THE present time is the best of all the year for inarching Vines. If the work is done now, when much of the wood is only half ripe, the canes unite quickly and form a lasting connection before pruning time. Perhaps, before going any further, it will be as well for me to explain for the benefit of your readers who are not familiar with the term "inarching," that it is simply the easiest of all ways of grafting, and there are none more sure of success. In beginning operations, supposing a white and black Grape to be growing side by side, the one may be inarched on the other. We intend doing this next year, where there is a Muscat Trovén and Black Hamburg growing together. There is not heat enough in the house to grow the first properly. When the Vines begin growing next year a shoot will be allowed to grow from the lowermost part of the Hamburg. This will be brought alongside the Muscat, and when ready the Hamburg wood will be joined to the Muscat, and the latter will be cut away altogether from where they are connected.

Inarching new sorts on old and inferior varieties is a very quick way of testing new Grapes. By inarching a small cane of any new sort on a good root this season it would make sufficient growth to bear fruit next year, but it would hardly do this perfectly if planted out.

In thinking of inarching any Vine, no matter what it is, the first thing to be considered is the securing of a proper stock. Some varieties of Grapes do very much better on another's roots than on their own, provided the stock is well selected. That is a point that must be considered to avoid failure. There are only two stocks which I dare recommend for every Grape; they are Black Hamburg and Muscat of Alexandria. Grapes that will fail on both of these stocks will not flourish anywhere. Other stocks might do well for a time, or perhaps altogether, but it is a chance which I would not risk with any valuable sort; but where neither of these stocks are growing others may be tried. Always choose the most robust grower. Never try one with tender roots like the Muscat Hamburg. After deciding on a stock, select the young Vine that has to be added to it. If it has to be sent for from a nursery, state what it is wanted for, and procure a cane becoming brown half way to the point.

In inarching one Vine on another the head of the stock is afterwards entirely cut away; therefore the nearer the root the two are united the better. Some Vines catch the wires close to the surface of the soil, others go up 2 or 3 feet to the first wire, and, as a rule, I have found this part the most convenient point to inarch at.

The operation of inarching is very easily performed, and no one need fail at it. With a very sharp knife cut a clean slice off the part of the wood where it is desired to make the connection. This slice should be 2 inches, or more in length and should penetrate the wood about

one-eighth. Then cut a piece off the one that has to be put on exactly the same size as the one just finished, so as when they are placed face to face the edges and other parts may meet. The best part to unite a young Vine is about a foot or so from the root. Nearly all young Vines which are inarched are in pots. When they are united near the ground the pot may rest on the ground; but when this cannot be done, the pot must be raised on a stool in a convenient position. Lay the cuts together, and about 1 inch from the end each way tie a round or two of matting. This assists greatly in keeping the canes firm and steady. When the cut parts are pressed against each other bind them closely round with soft matting and tie it firmly. This completes the inarching. The two will be united in a month, when the wood will begin swelling, and the matting must be cut, or the wood may suffer by the ligatures being too tight. Leave the top and bottom tie, however, in case anything might come against the united parts and separate them. It is well to leave these ties on until pruning time.

Water the roots in the pot regularly throughout the season. At pruning time cut the young Vine away close to the tie next the root, and do the same with the old rod above the tie. This will leave the new rod free to take the place of the one just cut out; and if all goes well it will bear fruit freely the following season.—A KITCHEN GARDENER.

AUTUMN ROSES.

"MORE about Roses!" I can well imagine some reader may exclaim on seeing the above heading. "More about Roses! Surely we have had a surfeit of Roses. Articles on exhibition Roses, on garden Roses, on old Roses, on new Roses; letters on climbing Roses, on Roses suited for towns, and last week on neglected Roses. What more can be said? Happy shall I be when I can parody the grace of the guest who was fed for one whole day on nothing but rabbits—

"Roses old, and Roses bold,
Roses tender, Roses tough,
I thank the Lord I've had enough."

No, my dear but testy reader, you may not sing your grace at present; we have no intention of letting Roses drop out of the columns of the Rose Journal for some little time, and there are still many subjects connected with the Rose left to us. What would you say, my friend, to an article on Roses suitable for churchyards? "Ah, good! (you chuckle); the best place for them. Bury them, sir, bury them, and along with them inter the Wyld Savage; then we shall have peace for a time, and can look to our Dahlias, and write about our Phloxes and Gladioli, and other seasonable flowers. Bury them." Meanwhile let me say a few words on autumn Roses.

What do I mean by autumn Roses? Well, Roses which do as well, if not better, in the autumn as in summer. By autumn I mean August and September—the present time, in fact. There are some Roses which bloom much later than the generality of Hybrid Perpetuals, whilst others bloom much better in the autumn

than in the height of summer. I do not know the reason; it must be something in the nature of the variety unknown to everybody but themselves. At all events, be the reason what it may, it is very rare to see good blooms of some varieties in exhibition stands. Some readers of these notes may wish for the names of a few Roses which are thus late in blooming, or which, according to my judgment, bloom better in the autumn. They may wish to prolong their blooming season, so as to have Roses of some kind or other from May till December; and they can do this if they wish by planting good free climbing sorts against a south wall for early spring blooms, and by filling the interval between the first and second blooms by planting Roses such as I am about to name. All of these are the finest exhibition sorts, for I grow none other.

First I would name that magnificent dark Rose *Pierre Notting*. How splendid the blooms are in a dry autumn! while in summer one rarely sees a good bloom. This Rose ought to be grown in partial shade. The place above all others for it is in a south border which has some huge evergreens or thick trees at the east end, so that the sun is not on the Roses till late in the day. I wish I could show the blooms which are on my trees to-day (August 5th).

Next to this Rose I should name *Duc de Rohan*. This fine old Rose never, to the best of my experience, comes to the front in June. It is a most distinct variety, being wonderfully built up, and of a bright crimson colour—altogether what one may call a superb Rose.

Then I would name *Emilie Hausburg*; I know of no better formed Rose than this. The colour exactly resembles that great delicacy strawberry ice, and the form is in my eyes perfection. Intensely double and globular, each petal encircles the other; you sometimes see an eye, but rarely in the autumn. In the summer this Rose does not bloom well, but now we have no better variety among the lights. *Abel Grand*, however, runs her very close. In the autumn I think this fine Rose is even grander than in the summer; and the same may be said of *La France*, the sweetest of Roses.

And now I come to a Rose concerning which I fancy there may be a great diversity of opinion, but I only speak from my own experience. With me this Rose rarely (and never this season), gives a good bloom in June and July. I allude to *Madame Victor Verdier*. As I have more than once said in the *Journal*, my Roses are grown in all aspects and in various parts of a somewhat extensive place. Wherever *Madame Victor Verdier* is, she is blooming freely and splendidly now. She is a magnificent Rose, and one I doubt not which will take a very high position in the Rose lists.

Still keeping to Hybrid Perpetuals, I should next name *Maréchal Vaillant* as being a grand autumn Rose. This old variety has been a little elbowed out of his place by some novelties, but in the autumn the old *Maréchal* is equal to the best of them. After the soldier I should place that somewhat capricious lady *Mlle. Annie Wood*. How rarely in the summer do we see her unfold her charms without having an eye too many; never, however, a black one, suggestive of a "fighting character," but at times a little green, as if she was jealous of the beauty of her sisters. But in the autumn she shuts her eye very close and blooms in the most bewitching manner. She always has intense colour, and now she has grand form. *Duchesse de Caylus*, again, is always better in the autumn, and *Horace Vernet* too.

And now I come to a Rose which I do not hesitate to class as an autumn Rose; I mean *Charles Lefebvre*. Over and over again have I seen this grand Rose far more magnificent in the autumn than I have ever seen it in the summer. It attains to a deeper colour, and is often more globular than earlier in the season. *Sénateur Vaisse* is another old variety which is grand in the autumn, as also is *Alfred Colomb*. There is, too, a variety not very well known but deserving of extensive cultivation, which is fine at the present time. I refer to a Rose called *Lena Turner*. This is a crimson Rose of lovely form, a little cupped, but each petal regularly placed behind the other, somewhat after the form of *Horace Vernet*.

There is one other Rose, not a Hybrid Perpetual but a Bourbon, which is never good except in the autumn, but is often grand then. *Souvenir de la Malmaison* is discarded by a great many exhibitors, but it is quite worthy of a place in any garden for its autumn blooms.

All the Teas are good autumn bloomers, and to mention any names would be to take a list and write them down one after the other. But one or two shy gems must be named which rarely open early in the season—viz., *Madame Jules Mar-*

gottin and *Comtesse de Nadaillac*. Of the Roses I have named there are beautiful examples blooming in my garden, and I doubt if during the summer I have ever had more lovely flowers than on this the 5th of August. There are not, of course, many, but what there are are good.

Another recommendation too have these autumn Roses, and that one which is not lightly to be estimated—their great fragrance. It is a perfect treat on a still August day when the winds of the capricious summer have at last sunk to rest, when there has been no rain for a week or so, when all nature is quiet and the soft balmy air does not stir a leaf in your rosery, to lift up a bloom of *Madame Victor Verdier* or *La France* and to inhale its perfume.

Then, again, autumn blooms are free from one great defect which their summer brothers and sisters have—they are rarely dirty. How often do we find grand blooms in summer bearing traces of the hard weather they have had to face—a burnt petal here, a damaged leaf there. How many a lovely Rose might plaintively sing—

"The Spring, she is a young maid
Who does not know her mind,
The Summer is a tyrant
Of most unconscious kind."

But in autumn the spring frosts and the cold summer nights are over, and if ever we have settled weather it is now; so the Roses can unfold their blooms at their leisure unprovoked by their foes. The grubs have become—something or other (I am no naturalist), and the caterpillars have blossomed into butterflies. The very aphides seem satiated with their summer feast, or are suffering remorse, or, perhaps (let us hope so), hot coppers from overeating, and they, too, leave the blooms alone, and so the Rose has a chance, and well does she avail herself of it.

"But what of strength of constitution?" I fancy I hear some one ask. "Does your autumn bloom last as well? Will it bear knocking about in Rose boxes like the summer Roses? or when you arrive at the autumn shows do not you find half your Roses showing eyes, or past and gone?" Well, perhaps *Charles Lefebvre* does not last so well now, but of the others that I have named I can never find any difference; but all depends upon the strength of the plant, and my experience tells me that the plant in autumn after good cultivation is stronger than in summer. My plants never seem to get hold of the soil till the summer is over. The soil is so light that it is a mercy the wind does not blow it away. But there is a silver lining to every cloud, and the soil in which a Hybrid Perpetual Rose can scarcely live is the very kind above all others for the Teas, which, however, I must not discuss now, or there is no telling when I shall stop, and the capacity of the *Journal's* columns is limited, and the patience of their readers too; so I will conclude by expressing my conviction that some autumn Roses are quite equal to any summer Roses, and that if anyone thinks that they are not, let him say so and expose the ignorance of a—WILD SAVAGE.

[Mr. George Paul's fine collection of Roses at South Kensington on the 7th inst. contained blooms we think richer in colour than any he has previously this year exhibited.—EDS.]

EUPATORIUM GRACILE ODORATUM.

THIS is by no means a common plant, though none are easier of propagation and culture. It is a sub-shrubby, half-hardy, or cool greenhouse plant, with opposite oblong lanceolate leaves, and terminal corymbs of white flowers and scented. *E. riparium* also has white flowers, and *E. Weismannianum* has rather large corymbs of bloom, but neither of them are fragrant. The heads of bloom of *E. gracile odoratum* are looser than those of the *Ageratum*, and, though white when first expanded, afterwards become suffused with pinkish purple. The habit is dwarf yet rather loose, and inclined in specimens to be decumbent, attaining to a height of 1 to 2 feet, flowering in spring up to June. Its flowering sprays are useful for cutting.

Propagation is readily effected by cuttings of the young shoots. If they are inserted in June and placed in a close frame they root quickly. When struck they should be potted off singly and grown in a cold frame, stopping them when 3 inches high, and again at that extent of growth they form good plants for flowering in 6-inch pots. If larger plants are wanted the plants may be stopped at every third joint, shifting into larger pots as they fill with roots. After flowering the flowered shoots only require to be cut back to firm growth, and when

the fresh shoots are an inch or two long remove most of the old soil and return to the same or a slightly increased size of pot. Shade for a few days and afterwards expose fully. Stop the shoots as they advance in growth, but not after February, when the final potting may be given.

Plants are easily obtained by seed, and they make more vigorous plants than from cuttings. If sown as soon as the seed is ripe good plants are had for next year's bloom. Seedlings, however, flower rather later than plants from cuttings.

Three parts loam with a fourth of leaf soil or well-decayed manure will grow the plants well, good drainage being provided. Free watering is necessary, and a light airy situation. In summer the plants may be placed outdoors, housing them before frost.—G. ABBEY.

PACKING.—No. 3.

PEACH BOXES are 4 inches deep inside. Each fruit is wrapped in tissue or other very soft paper, and afterwards in wadding. All are then laid in the box so closely that they cannot possibly move, corners and all interstices being stuffed with wadding or waste paper, and the box altogether made just a little more than full, remembering that it is even better to crush the fruit a little in packing than to allow the possibility of its moving about during transit. However, there is no difficulty in packing the fruit in such a manner that unless it meets with extremely rough usage it will arrive at its destination uninjured. The best wadding is the cheapest, it being the most elastic, and can be used many times over. There is more fruit injured by being packed too loosely than there is in the opposite direction. People are afraid to give it a little pressure, and then when it passes through the rough hands of the carriers and turned upside down, endways, sideways, and thrown about any way except the right one, some of the fruits shift closer together, leaving a little space perhaps at one end, and then all is over, for every movement afterwards will make matters worse. We must always bear in mind that a package is liable to be thrown from the top of a railway carriage on to the platform, and we must pack accordingly. If it does not happen to receive this sort of treatment all is well, and if it does all is well too so long as the necessary precautions have been taken to have plenty of elasticity combined with firm packing.

Every fruit has to be perfectly ripe and ready for immediate use when packed for a gentleman's table, because we cannot expect those whose hands it afterwards passes through to have the requisite knowledge of judging when it is fit for use; this takes a considerable amount of experience, which even those who profess to have it are often short of. In packing for a London fruiterer the case would be entirely different, as the consignee would probably know more about the peculiarities of the fruit than the sender. Something, too, depends on the manner of gathering the fruit. Once every day at least all ripening fruit on the trees should be tried, grasping it in the hand in a similar way as one would a cricket ball, dividing the pressure as nearly as possible equally all round and giving a gentle pull. If the fruit is ready the stalk will either come out of it easily, or the fruit will be felt to be slightly elastic and may then be pulled off, laying it on wadding in a basket or box at hand for the purpose. A practised hand never bruises a fruit in gripping it in the way I have tried to describe; it is only the unskilled who bruise by pressing too much in one place, and perhaps with the finger and thumb only instead of with the whole hand. The fruit is not generally fit for table for a week or ten days after it is gathered. It should be kept lying on wadding in the fruit room or other suitable place, and be examined and placed on fresh dry wadding every second or third day, as the wadding sometimes gets damp underneath the fruit.

Figs are packed in a similar way to Peaches, and are rather more difficult to manage, as a Fig is of no use at all unless it is fit to be put in the mouth immediately it is taken from the tree. This is especially the case with White Marseilles, which is perhaps the best and the worst sort in cultivation, according to the time and manner of gathering it. It must be allowed time to attain to its delicate yellowish-green colour, be quite soft at the eye, and the skin just commence to crackle. It is good only under these conditions, and of course wants exceedingly good packing. The sort named above and the Brown Turkey are the best I know for both indoors and out. Instead of using tissue paper I generally wrap Figs in a soft Vine leaf (Hamburgh preferred) and afterwards in wadding.

Where very soft, clean, elastic moss can be had I have no doubt it would do as well, or nearly as well, as wadding; but nothing should be used for the purpose which would be likely to partially wither, and consequently leave a vacant space in the box.

Strawberry boxes are 10 by 8 inches outside and 2 inches deep inside. A layer of wadding is placed at the bottom, and then each fruit is laid on a separate leaf, so that no two fruits can touch. The manner of proceeding is something like the following: The fruit is gathered carefully by the stalk and placed in single layers in cane-bottomed sieves; if wet, as it frequently is, it is left in a dry airy position for a time previous to packing. The operator when commencing to pack places the sieve to the right of his box and plenty of dry Strawberry leaves, with the stems picked-off closely, in front of him. The wadding being placed in the bottom of the box, he commences by placing a leaf at the corner nearest his left hand in such a way that the fruit when laid on it will neither touch the side of the box nor the wadding at the bottom; he then takes a fruit by the stalk in his right hand and places it sideways with the stalk outwards and depressed a little to the bottom of the box, so as not to be in the way of other fruits to follow. He holds the fruit in position by the stalk with his right hand, while with his left he takes another leaf and places it so as to protect the second fruit from the first one as well as from the wadding; he now holds the leaf, gently pressing against the fruit with his left hand, and the right is free to take up another fruit. He works in a line away from himself, and then, after making the first line perfectly secure, he follows with a second one, packing all so closely together that a fruit cannot possibly move, and yet without bruising one. When the layer is completed it is covered with a single layer of Vine or Strawberry leaves, then a layer of wadding over all, and the lid is fastened. If the fruit is small, the depth of box I have given will require an extra layer of wadding or more leaves; but 2 inches is none too deep for good fruit of President or Dr. Hogg. From four to six boxes are tied together, except when they are enclosed in other packages.

Grapes are packed in stiff cardboard, rolled up to a point at one end as the shop boys do sugar papers, turning the ends carefully down, and wrapping afterwards in brown paper so as to keep all right without tying. A good size for boxes is 2 feet by 1 foot, and 7 inches deep inside. The interstices are filled with chopped straw.—WILLIAM TAYLOR.

ROSE GOSSIP.

ALTHOUGH it may need some apology on the part of an obscure Rose-grower for presuming to record his humble opinion respecting Roses and Rose-exhibiting in a Journal so replete with information from the highest authorities, yet perhaps it may be as well to have the subject ventilated occasionally by growers in a small way, and on such an understanding I will proceed. Respecting the new varieties I can say but little, for although I possess strong plants of most of the new French kinds, the bloom has not yet been sufficiently general to enable me to judge. I may mention in passing that from observation and information we may find some of the best among the following:—Madame Devert (Pernet), Madame la Baronne de Medeni (E. Verdier), Madame Sophie Fropot (Levet), Marie Louise Pernet (Pernet), Marquise A. de Murinais (Schwartz); but of these I hope we may soon have fuller information from some of the leading growers. I have bloomed the new Tea Triomphe de Milan, and have every confidence that it will prove an acquisition. Respecting last year's lot, English and foreign, I am disposed to think favourably of Abel Carrière, Duke of Connaught, Duchesse de Vallombrosa (very good), Duc de Montpensier, Jean Liabaud, Madame Prosper Langier, Magna Charta, Marguerite Brassac (superb), Mrs. Baker, and Oxonian, but I cannot at present endorse the good opinion expressed regarding Avocat Duvivier, Empress of India, Madame Ferdinand Jamin, Mlle. Emilie Verdier, Queen Eleanor, Triomphe de France (a good bedder), and others, of which the names I fancy will speedily drop out of our lists. Among recent acquisitions I think we may class Casimer Perrier, Comtesse de Serenyi, Hippolyte Jamain, La Rosière, Mons. E. Y. Teas, Rev. J. B. M. Camm, Royal Standard, Sir G. Wolseley, and Star of Waltham. All these I think are well worthy of cultivation for exhibition purposes.

One word respecting garden Roses, and especially summer Roses, for I cannot banish them altogether; surely every rosarian ought to find a place for such old favourites as

Charles Lawson, Coupe d'Hébé, Juno, Paul Perras, Paul Ricaut, Comtesse de Lacépède, Fulgens, Madame Plantier, Madame Zoutman, &c. I rejoice in the possession of trees or bushes of the above and other varieties, and I can truly say they are worthy of cultivation by all those who can see beauty in a Rose not calculated to shine upon the exhibition table in the present day. Some of these old favourites of my youth have disappeared altogether from the catalogues, where I look in vain for a few I would fain replace. Does anyone grow these Roses now—Princess Clementine (H. Prov.), Comte Plater (H. Prov.), George IV. (H.C.), Charles Duval (H.B.), Le Capitaine Sisolet (H.B.), Beauty of Billiard (H.C.)? Methinks I shall obtain but little sympathy from a "WILD SAVAGE," but at least "A PARSON'S GARDENER" may claim a kindred spirit in one who still admires the good old garden Roses, although he has achieved, and hopes still further to achieve, some little success as—AN AMATEUR EXHIBITOR.

STRAWBERRIES FOR LIGHT SOIL.

No doubt the success of "AMATEUR," as detailed on page 110, is primarily attributable to his keeping the surface of the soil protected from the rays of the sun. When this important matter is attended to Strawberries may be grown almost as well in tolerably light and deeply worked soil as on stronger ground, and especially if the light soil is kept firm by little or no digging being done between the rows. It is important to remember that some light soils appear to be favourable to the Strawberry. The soil of many of the fields in Kent, for instance, where Strawberries are grown by tons, is light and gravelly, but the plants bear heavy crops for two or three years. The soil of "AMATEUR" must be in some way peculiarly suitable to the Strawberry, or the crops would not continue so profitable for "eight years, and likely to go on for another eight." It is not the mode of culture that has been adopted that has rendered the plants so perennially profitable so much as the natural adaptability of the soil to the crop. I do not suggest that the culture has been wrong, for the results prove that it has been right; but the same plan if carried out in many light soils would probably have a different and less favourable result. It is a rough-and-ready mode of culture that I have occasionally seen successful, but far frequently the reverse has been the case.

The more reliable practice to adopt on light soils is to plant strong early runners annually. I have often planted such runners in August just a foot apart, leaving out every fourth row for a path, and have gathered a splendid crop of dessert fruit from such beds the following year. The plants when planted thus closely do something to shade the soil, and lawn mowings do the rest. I have occasionally allowed these beds to remain untouched a second year, and have gathered from them a prodigious crop of smaller fruit for preserving, but after that they have been of little further use.

I prefer clearing away the runners immediately after gathering the crop, not cutting off any of the foliage of the plants, and then covering the soil between the plants with lawn mowings, to the somewhat rude practice adopted by "AMATEUR." Although it has answered well in his case I do not think it is generally recommendable.

Mr. Douglas recommends the plants being placed in slight cavities. The plan is good provided the cavities are "slight." I once saw a large bed planted where the word "slight" had been largely interpreted. The plants had been placed in considerable hollows, and in the winter the heavy rains washed the light soil into them, injured the hearts, and spoiled the crop and plants.

Some of the varieties mentioned by Mr. Douglas I have not grown. One sort I shall look forward to with special interest—Loxford Hall Seedling. A good free-bearing late Strawberry is greatly required. Frogmore Late Pine, Elton, and Eleanor are all shy bearers with me. The last-named is the larger of the three, and if not sweet is always very welcome on the table on account of its good appearance. Elton is of good size, also acid.

I agree on all that has been written on the general usefulness of Keens' Seedling, but if I were condemned to grow one variety only it would be Sir Joseph Paxton.—W. S. P.

NATIONAL CARNATION AND PICOTEE SHOW.

In the reports of the Show held at Manchester last week, the Journal says Mr. Simonite won premier both for Carnations

and Picotees. In the *Gardener's Chronicle* report it is stated that the premier Picotee was Chadwick's Miss Chadwick. Which is right?—EX-EXHIBITOR.

[I believe the *Gardener's Chronicle* report is wrong, as I have two independent reports of the Show, and one from Mr. B. Simonite, in which he says, "I also took premier Picotee with Teresa, light rose edged, though some thought my bloom of Mrs. Allerof was the best." Another correspondent says, "Ben was first (and premier) with Teresa, a good bloom showing quality all over." As the premier flower in the Exhibition is of great importance to fanciers, and as Mr. Simonite won both with his own seedlings, I think this explanation necessary.—J. DOUGLAS.]

BY THE SEASIDE.—MEADOW SWEET.

No greater contrast in gardens could be found than in two on which I now look daily, and which are side by side, divided by a low party wall. One of those gardens is totally covered with unmown grass, yet it was once cared for; but the hands which once tended it, and the head which arranged it, and the heart which loved it, are at rest in the cemetery. There remains one plant which, though neglected, still clings to the wall, and still yields flowers. It is a Passion-flower, and suggested a flower sermon that would be misplaced to repeat here. The other garden is well cultivated, and without any regard to order let me note some of its tenants. There are Tamarisks with their pink flowers now out and peeping from among the multitude of fine pale green needle-form leaves. Near it is the *Viburnum Lantana* or "Wayfaring Tree," a name which suggested these lines—

"Wayfaring Tree! what ancient claim
Hast thou to that right pleasant name?
Was it that some faint pilgrim came
Unhopedly to thee
In the brown desert's weary way,
'Mid toil and thirst's consuming sway,
And there as 'neath thy shade he lay
Bless'd the Wayfaring Tree?"

The Rose trees are numerous, and all exempt from mildew and brown-blotched leaves, seemingly indicating that a climate uniformly temperate and air impregnated with saline particles, iodine, and other marine emanations, are preventive of mildew as they are of other fungi. Among those Roses, far superior to their junior relatives, are two genuine and ancient Moss Roses—giants compared with others dwarf of stature and flimsy-flowered, and

"Vaulting o'er banks of flowers that glow
In hues of crimson, gold, and snow."

The old gardener who was hoeing among the border flowers is a quaint character, full of practical knowledge, but totally ignorant of garden literature. You will need no other proof of this than that he had never before heard of the *Journal of Horticulture*; yet he wished for information, and asked who the "Polly Hanthus" was called after! This paralleled the inquiry of the woman who during the Peninsular War asked, "What Sally Manker Lord Wellington had been with?"

The old gardener I have mentioned was earnest in commending some of our wild flowers for garden ornamentation, and Mr. Abbey thus writes of one—"A moist piece of land inclining to a brook is profusely studded with the Queen of the Meadow—Meadow Sweet (*Spiraea Ulmaria*), adorning moist meadows, brook and river banks, and ditch sides, perfuming the air with its sweet Hawthorn-like scent. Scattered patches or even clumps, as we see them in pleasure grounds, are delightful, but to meander amid acres of such sweetness is truly pleasing alike to sight and smell. A voice close by pronounced it 'A beautiful thing, I like its scent far before *Spiraea japonica*, I'll warrant it would force well; in fact, someone stated in the Journal that it had been so employed successfully.' 'In what Journal were the statements made?' 'In the *Journal of Horticulture*.' My friend went on—'A great batch of it would look well and smell better than the honey-like sickening smell of *Spiraea japonica* in any moist piece of land, as the sides of a feeding stream to a pond; and patches here and there in pleasure grounds would be superb, especially if planted in well-manured ground, and occasionally top-dressed with decomposing matter, with good waterings and doses now and then of liquid manure. It would make a famous specimen, just what is wanted in front of shrubberies, for see how fine it is wild, and imagine how much finer it would be under cultivation.' I must admit now, as I did then, the force of those remarks, but I must return and pass from plants wild to plants

cultivated; yet I would note that I observed few Sloes, fewer Crabs, many haws, lots of berries, Hollies' and others, and if bloom be any guide there will be an abundance of haws and a plentiful crop of Blackberries—a good prospect of food for our feathered friends in autumn and winter."

STOCKS FOR ROSES.

In reply to "HOMUNCULUS," I do not quite see how his suggestion as to the stock that best suits each Rose is to be carried out in the Rose election. There would be a great variety of opinions on each separate Rose, and even then much would depend on the soil. Not many years ago—two I think—we had the battle of the stocks, and perhaps if "HOMUNCULUS" refers to that he may see something that will suit him. Such an election could only be conducted by singling-out some half dozen Roses, and asking on what stocks they have been found to do best. But then, again, how difficult to reply. Take Charles Lefebvre for instance, and suppose circulars were sent out to A, B, and C thereon. A replies S.B., the Rose having succeeded admirably thereon, he not having tried or found it necessary to try any other. Now possibly the soil exactly suiting the Rose, it would have succeeded as well on Manetti. B may have tried it on every stock unsuccessfully, the climate being unfavourable.

From the replies I have already received as to the present exhibition election, I may say that some startling results are probable, as already two persons, considering it right to reply to the question by giving their experience in their own Rose grounds of the best forty-eight varieties, wholly exclude from the forty-eight each one a different Rose, because, treat it as they would, they could never succeed in growing a bloom fit for exhibition or that could be placed in a stand without ruining its chance. These will be noticed in due course.

"HOMUNCULUS" mentions the glorious bush of *Souvenir de la Malmaison*. I have a standard bush of *Charles Lawson*. I budded it quite sixteen years ago; the stem is now at least 2 inches in diameter, the head is at least 5 feet through, as for a couple of years I have let it grow as it pleased. This year it has been a sight. I have cut at least one hundred of its beautiful pink blooms, whilst as many more have remained on the tree. The tree stands as a tree, and has long since declined any support.—JOSEPH HINTON, *Warminster*.

VINES.

THE readers of the *Journal* may recollect that I wrote an article some months since on pruning Vines on the quarter-rod system—a plan something between the rod and the spur system. This season we are reaping the full benefit of this plan, for we have not only had to cut off one-half the bunches, but at this time I am sure we have left one-third too many. At the same time, since there is a much larger amount of wood left by this plan than on the long-rod-and-spur system, a Vine can bear a heavier crop.

I will first refer in a few words to my plan. Supposing the main stem to be 16 feet in length I allow four laterals to ramble, say 6 feet in length; when I perceive that the wood is getting ripe I cut each rod down to 4 feet. By this plan I get 4 feet of young wood thoroughly ripe. If I had allowed a rod to run up the whole length of the main stem only half of this rod would be thoroughly ripened; at any rate, the other half would not be in such a condition for bearing fruit as if only 4 feet of a rod had been left. This I have now proved.

With regard to the spur system. In order to keep these spurs within bounds it is necessary to cut them off nearly close to the main stem, so as to get a bud from the axil, which is never so strong or so well developed as the buds further from the axil; besides which the lateral has in all probability given a bunch the previous year. On my plan four or five new thoroughly ripened rods are produced every year on which no fruit is allowed until the following season.—OBSERVER.

AURICULA APHIS.

WHEN I last wrote on the re-appearance of this pest I had no idea of the extent to which it had gone, but on looking over the next frame I found that there was hardly a plant that was not affected by it, convincing me that *Auricula* growers have a most formidable enemy to contend with. I do not think that I was sufficiently alive to its insidiousness when I reported, but I feel that however venturesome it may be to turn all my stock out again I must do it, and indeed have already begun.

It seems to insinuate itself first into the creases of the stem and under the roots which emanate from it just below the surface, and then to work its way down. It does not seem that dipping either in *salus* or *Gishurst* kills it; so I have taken a small painter's brush and brushed diligently all round the collar and every root separately, examining every part with a pocket lens, and afterwards dipped it in a solution of one or the other of the above mixtures, and when it has sufficiently dried have them repotted. If I do not get rid of it thus I shall be in despair.

I wrote at once to Mr. Llewelyn who first drew attention to it, and in his reply he says, "I find the aphid on my plants, although they were all thoroughly washed and repotted in clean soil in May and June. Apparently the early life of the aphid would be within the tissues of the root where the soft soap will not reach them, or in the wrinkles of the neck where it seems first to appear. I have but little of it; still enough to warn and put me on my guard."

This morning's post brought me a letter from an *Auricula* grower in the midland counties, who says, "Since I saw the account of the disease that has destroyed many of your *Auriculas* I have carefully looked over my plants frequently; perhaps from time to time I have found from twenty to thirty aphides. It appears to be a small woolly aphid quite white. The downy substance is deposited round or on one side of the plant just above the soil and as far as the roots are exposed, and even extends to roots making their way to the surface and not connected with the stem; above the soil they become covered with a white down or mould." This is evidently the same, although the description does not quite tally with mine. My correspondent has dressed with tobacco ashes, and although he thinks it efficacious I doubt it very much. We want to know something more of aphid's history. It is distinct from the woolly aphid of the Apple, and is a terrible nuisance to anyone who is visited by it.—D., *Deal*.

THE CIDER FRUITS OF HEREFORDSHIRE.

OUR readers will have observed an advertisement which appeared a few weeks ago in the pages of this *Journal* announcing the publication by the Woolhope Club of the "Herefordshire Pomona." It is now many years since Mr. T. A. Knight produced his "*Pomona Herefordiensis*," the object of which was to illustrate the cider Apples grown in that county, and to introduce to the attention of orchardists some varieties of his own raising which he expected would supersede the old varieties grown for cider, and which he considered had become so much exhausted as to be on the brink of extinction. Happily Mr. Knight's fears have not been realised any more than his hopes; for those varieties of his own raising which were intended to take the place of the older ones have received little attention from planters, and in the county in which they were raised they are perhaps less known and appreciated than they are in other parts of the country.

The "*Pomona Herefordiensis*" of Knight was, even at the time of its publication, a very fragmentary and imperfect work. The plates by which it was illustrated were not specimens of high art or even of average merit, and the letterpress that accompanied them did not consist of such descriptions of the fruit as would enable anyone to identify the variety. The members of the Woolhope Club, being convinced that a matter so intimately connected with the great commercial industry of their county was worthy of a better representative, have determined to issue a "*Herefordshire Pomona*" which shall be worthy of the subject; and while it will embrace all the native and other varieties employed in the production of cider, it will also figure and describe others which are used for dessert and culinary purposes and which are not indigenous to the county, being cultivated merely on account of their merit. In this way the "*Herefordshire Pomona*" will become of wider interest; and we doubt not that if it receives the support of all fruit-growers, as we have no doubt it will, its scope may be extended so as to take in all the varieties of fruits worth cultivating in the gardens and orchards of the country generally. We know that the best artistic and literary talent are already engaged in the work; and from what we have seen of the original portraits we are convinced that the Woolhope Club have undertaken the production of a work which will be of universal interest, and one that will be of great usefulness to the country at large.

Those who appreciate the possession of such a work will obtain all information respecting it on application to J. Regi-

nald Symonds, Esq., Honorary Secretary of the Club, Bridge Street, Hereford.

As an example of what the letterpress will be which will accompany the beautiful coloured plates, we subjoin a specimen descriptive of the old Herefordshire Apple the Fox-whelp.

THE FOX-WHELP APPLE.

"Cider for strength and a long-lasting drink is best made of the Fox-whelp of the Forest of Deane, but which comes not to be drunk till two or three years old."—(*Appendix to Evelyn's "Pomona."*)

The Fox-whelp Apple is the favourite cider Apple of Herefordshire. Its origin and its singular name are alike obscure. Mr. Knight in the "*Pomona Herefordiensis*," published in 1811, thought it "certainly a true Herefordshire Apple," and it may readily be supposed that the stray seedling sprung up near a fox's earth, and thus when it had shown its character

Fig. 28.—Fox-whelp.

obtained its name. Some devoted admirers think they see in the eye of this Apple a distinctive resemblance to the physiognomy of a young fox, but here surely the name has guided the imagination. Wherever it grew the brilliant colour of its

Fig. 29.—Fox-whelp.

fruit would render it conspicuous, and its taste with a judge of Apples would proclaim its merit.

The earliest record we have of the Fox-whelp is by Evelyn in his "*Pomona*," which is an appendix to the *Sylva* "concerning fruit trees in relation to cider." This was first published in 1664, and at that time and long after the great Apple of Herefordshire was the Red-streak. The Fox-whelp is disposed of in a few words—"Some commend the Fox-whelp." Ralph Austen, who wrote in 1653, makes no mention of it when he says, "Let the greatest number of fruit trees not only in the orchards but also in the fields be Pear-maines, Pippins, Gennet-Moyles, Red-streaks, and such kinds as are known by much experience to be especially good for cider." Neither is any notice taken of it by Dr. Beale in his "*Herefordshire Orchards*," written in an epistolary address to Samuel Hartlib, Esq., in 1656. The first notice of it after Evelyn is by Worledge in 1676, who merely says, "The Fox-whelp is esteemed among the choice cider fruits." In Evelyn's time it appears to have been regarded as a native of Gloucestershire, for Dr. Smith in the "*Pomona*" when writing of "the best fruit (with us in Gloucestershire)" says, "The cider of the Bromsbury Crab and Fox-whelp is not fit for drinking till the second year, but then very good;" and in the quotation at the head of this paper "a person of great experience" calls it "the Fox-whelp of the Forest of Deane."

Although all who have noticed the Fox-whelp up to this period have spoken of its merits as a cider Apple its cultivation must not have been on an extensive scale, otherwise it would have been better known than it appears to have been. Even Philips in his celebrated poem on "*Cyder*" seems as ignorant of its existence as many of the writers on orchards were at that period. The first appreciative notice of it with which we are acquainted is found in a letter to a friend written by Hugh Stafford of Pynes in Devonshire, Esq., bearing date 1727. He says, "This is an Apple long known, and of late years has acquired a much greater reputation than it had formerly. The fruit is rather small than middle-sized, in shape long, and all over of a dark red colour. I have been told by a person of credit that a hogshead of cider from this fruit has been sold in London for £8 or eight guineas, and that often a hogshead of French wine has been given in exchange for the same quantity of Fox-whelp. It is said to contain a richer and more cordial juice than even the Red-streak itself, though something rougher if not softened by racking. The tree seems to want the same helps as the Red-streak to make it grow large. It is of Herefordshire extraction."

The fruit is roundish, inclining to conical or ovate, with an uneven outline, caused by several obtuse ribs on the sides, and which terminate in ridges round the eye; in good specimens one side is generally convex, while the other is flattened. Skin beautifully striped with deep bright crimson and yellow; on the side next the sun it is more crimson than it is on the shaded side, where the yellow stripes are more apparent. The surface is marked with several dark patches like scabs, which are a never-failing character of the Fox-whelp. Eye very small, set in a narrow, shallow, and plaited basin; segments short, somewhat erect, and slightly divergent. Stalk three-quarters of an inch long, obliquely inserted by the side of a fleshy swelling, which pushes it on one side and gives it a curving direction. Flesh yellow tinged with red, tender, and with a rough and acid flavour. Calyx-tube funnel-shaped. Stamens marginal. Cells of the core wide open. It belongs to group 10 of Dr. Hogg's New Classification of Apples.

(To be continued.)

ROSES AT FERRIÈRES.

It may be interesting to your readers to know what varieties of Roses are grown by Mr. Ferdinand Bergman at Ferrières. What is wanted there is not to have fine Rose trees but plenty of blooms, as the demand for them is very great. About fifteen thousand blooms are required and used in the course of the year for bouquets, table decorations, &c., for Ferrières and for Paris as well. You may therefore imagine that to supply such a quantity of Roses it is necessary to have a great number of those varieties which bloom very freely. Many varieties are grown, but those grown in quantity are the following:—Paul Neron, Maréchal Niel, Baronne de Rothschild, Gloire de Dijon, Madame Boll, Madame Lacharme, Annie Wood, La France, Belle Lyonnaise, Charles Verdier, Jules Verdier, Souvenir de la Malmaison, Souvenir de la Reine d'Angleterre, Elizabeth Vigneron, Madame Falcot, Capitaine Christy, Le Roi, La Reine, Général Jacqueminot, besides a number of other Teas and Noisettes. The varieties preferred for forcing are Le Roi, La

Reine, Jules Margottin, Madame Boll, Maréchal Niel, and Gloire de Dijon.

No Roses are grown in pots; those for forcing only are placed in pots to be taken to the forcing houses, and after they have done flowering they are planted in the open air. Every spring a thick dressing of short dung is placed between the Roses, and in the autumn the ground is ploughed. Every three years the trees are removed and planted in a trench 2 feet deep, with horse and cow dung mixed and in quantity. The pruning is done in March and April after the frosts are over. About one half of the Roses are standards and the other half dwarfs, some on Briars and some on their own roots. It has been found that Roses on Briars bloom freely, while Roses on their own roots give much better flowers. As climbing Roses they have especially Maréchal Niel and Gloire de Dijon. At the end of December they began cutting Roses in the houses from Le Roi, La Reine, and Jules Margottin; that is about their usual time.

Paul Neron, which is not much liked in England, is put in the first line at Ferrières, and is considered the best for their purpose. It grows well, has shoots of 2 or 3 feet long, gives large blooms, and stands well; but above all its first quality is that while all other trees round it suffer from mildew, it is the only one that is not so attacked.—ERNEST BERGMAN.

YORKSHIRE FRUIT CROPS.

HAVING previously alluded to this subject, I will now complete my observations upon the fruit crops of this year.

Apricots on every aspect but a south one and well protected are a complete failure. The crop against a south wall is moderate. The only kinds that carry a fair crop are Blenheim or Shipley, Royal, Kaisha, and Moorpark.

Peaches and Nectarines against a south wall and well protected have totally failed. The trees were a pitiful sight from the prevalence of "blister." The kinds that have suffered most are Violette Hâtive and Barrington, the most healthful being Malta, and next to it Noblesse.

Plums must be recorded a failure. The only kinds that have fruit against walls are Early Orleans, Pond's Seedling, Victoria, and Yellow Magnum Bonum, those having a moderate crop, whilst there is just a sprinkling of Belgian Purple, Coe's Golden Drop, Jefferson, and Green Gage. In the open ground Orleans and Victoria carry a moderate crop, there being a sprinkling of Early Prolific and Oullins Golden Gage.

Cherries in the open have signally failed, the only one with fruit being Impératrice Eugénie, but bush or pyramid Morellos are loaded. The north aspect of the walls are occupied by Cherries. Morellos carry a heavy crop, and so do May Duke, Harrison's Heart, and Elton.

Pears are for the most part fruitless. The only kinds carrying a crop of fruit with the benefit of a wall are General Todtleben, Hacon's Incomparable, Glou. Morceau, Alexandre Bivort, Napoleon, Bœurré Diel, and Bergamotte Espéren, with a fair crop of Doyenné d'Été and Jargonelle, and just a sprinkling of Bœurré d'Amanlis, Passe Colmar, Winter Nelis, and Joséphine de Malines. In the open Jargonelle, Williams' Bon Chrétien, Bœurré Diel, Bergamotte Espéren, and Zéphirin Grégoire have fair crops.

Apples may be said to be a fair crop, some kinds being loaded, notably Warner's King (but the foliage much cut and the fruit "pitted"), Cox's Pomona, Dumelow's Seedling, Bedfordshire Foundling, Holland Pippin, Northern Greening, Cellini, Lord Suffield, Mère de Ménage, Cox's Orange Pippin, Margil, Court of Wick, Irish Peach, and Yorkshire Greening. Keswick Codlin and Manx Codlin, with many others, are almost destitute of fruit, but considering the great scarcity of other fruits it is gratifying to see even a few Apples.

Bush fruit, particularly black and red Currants, carry very heavy crops; but Gooseberries are variable, some kinds being heavily cropped, such as Whitesmith, Antagonist, Crown Bob, and most of the Lancashire kinds, but Red Warrington is very thin. Raspberries a good crop, but late.

Strawberries a good crop, that of President being enormous. I do not grow many kinds, our wants being met by Keens's Seedling, or that form of it often confounded with Sir Harry, which is a great cropper and a first-rate forcer. La Grosse Sucrée is not a great though a certain cropper both out and indoors, and one of the best for forcing. Sir Joseph Paxton is producing heavily upon two-year-old plants, but last year's runners are sparse of fruit. Duc de Malakoff is neither so heavy in crop nor the fruit so large as usual, whilst Sir Charles

Napier is heavily cropped. Hélène Gloede, a later and improved Frogmore Late Pine, is good, and Luas is one of the finest Strawberries in cultivation.

Fruit trees generally are making very vigorous growth, and have for the most part clean healthy foliage. Aphis has been very troublesome upon Plums, making the leaves curl, and the shoots have a distorted appearance; but as I keep the growths closely stopped most of the aphides disappear with the removed sprays. I like as many leaves as possible around the spurs, and not long sprays. There has been a great prevalence of grubs and caterpillars that feed upon the foliage of fruit trees, all of which have great enemies in birds. Sparrows have looked after the Apricot grub so well as to need no help from us. The number of grubs sparrows destroy in feeding their young must be enormous—not only in the nest, but for a time after the young take wing. Sparrows only do harm when in undue numbers, as they may be in a town garden.

I write from north Yorkshire, over 500 feet above sea; soil a peaty loam with a variable subsoil, mostly sand, gravelly, or rocky. In the orchard, which is not less than 100 feet lower than the garden and sheltered on every side by woods, the crops of fruit are more scant; no Plums except Farleigh Damson, no Pears, and not many Apples.—G. ABBEY.

FERTILISERS AND THEIR APPLICATION.

As it is clear that I have been misapprehended by "J. B. K.," a few further explanatory remarks become necessary. I certainly do not give up the point of quantities, for the reason that I never recommended any such extravagant applications as those deduced by your correspondent. After I stated that not a particle of guano was applied between the rows of Peas (more than four-fifths of the ground), it was, I think, superfluous for "J. B. K." to assume that it was used there. As to the same quantity of liquid manure having been applied to a square foot of the surface of an Onion bed that was poured into the hollow trench of a Pea row, anyone having sufficient experience in watering such crops knows to be impossible in the ordinary mode of watering: hence deductions founded on theory alone are so often fallacious.

I was requested to name what I considered a proper strength of using guano water for garden crops, also how much water to apply to those crops. I advised mixing guano at the rate of something less than 1½ oz. to a gallon of water, and recommended as much being applied as the ground would take. I am unable to give more practical advice on watering than that. If crops require watering they should be watered thoroughly, for much experience has satisfied me that half watering does more harm than good. I also and particularly recommended (bearing in mind the large quantities of water that some ground will take) that if the crops are first watered with clear water the ground will not take more than half the quantity of liquid manure that would otherwise be required. That I submit is the best—the most economical and effectual—way of using liquid manure, applying fertilisers, and when so applied the quantities named are not extravagant at all, but are reasonable. I further, in order to prove that the strength of the guano water named was not injurious (poisonous), detailed my experience of using it in an extraordinary season, and the crops when so treated showed conclusively how beneficial the applications were, for such crops were full and luxuriant when all surrounding crops that had no such cultural assistance were dead. I have great respect for the labours of scientific men, but none for a practice that results in dying crops.

In an exceptional season like the one referred to—such a season as I do not hope to see again, demanding such exceptional labour to preserve the crops—guano when applied in farm or double farm quantities and left, as has been advised, to be washed-in by the rains, is simply wasted. How can it be otherwise when no rain falls for several weeks, and when the crops are "dead failures?" On the farm I alluded to I know it is a fact that more than twenty times the guano was used than was applied in the garden, and yet the farm (as the owner well remembers) was a complete failure that year, while the garden, as he readily admitted, and admits still, was a great success.

I will now go a step further, and submit proof that even in the exceptional year named the large quantities of liquid manure used were not superfluous. That the crops appropriated all the water I do not for a moment suggest. The atmosphere may have absorbed half of it for aught I know to

the contrary; but this I do know, that had the water, &c., not been given the crops would have been worthless, as I think the following facts, extracted from my garden diary, will afford sufficient evidence. On June 27th, 1868, twelve long rows of *Ne Plus Ultra* Peas were sown in unmanured trenches. The heat was intense; no rain nor dew for several weeks. The Peas came up blue and wiry. I was satisfied that nothing could save them but heavy soakings of liquid manure. My kitchen garden man differed. Four rows were placed at his disposal for him to do as he liked with. Two of the rows were not watered at all, and the Peas died when 6 inches high. The other two were watered with clear water, and the Peas attained a height of 3 feet, and two small dishes of Peas were gathered from each. The other eight rows were soaked once a-week with guano and salt water, quite filling the trenches at each watering. Finer rows of Peas than these I never saw. They grew luxuriantly, especially after the autumn rains commenced, and Peas were abundantly produced; in fact the crop was a full one, and no mildew was seen on the foliage. "J. B. K." is quite welcome to consider that the guano and labour was wasted, but I know the owner who had both to pay for did not think so, and I am of the same opinion now as he was then.

I do not dispute that your correspondent has had some practice with fertilisers, but I think he has never produced a full and regular supply of fruit and vegetables for thirty people from an acre of ground, and this for several years without a failure, or he would not betray so much fear of poisoning the vegetables or advocate homœopathic doses of fertilisers. Such limited applications may do in some soils and under some circumstances, but to enable the majority of gardeners to meet the heavy demands on them and the soil they cultivate liberal applications become necessary, and are the most profitable in the end.

I agree with Mr. Douglas and "J. B. K." that good farm-yard manure is preferable to any so-called artificial dressing, but how few there are who can obtain enough of it! I do not hesitate saying that not one kitchen garden out of twenty is sufficiently manured and trenched. I form my opinion on the practice of the best of the London market gardeners. Your issue of the 2nd inst. contains a note on the heavy manuring that is adopted in the "market grounds," and the success of some of Mr. Bagley's crops are alluded to. It so happens that those grounds were my school for kitchen gardening; and if manures are so poisonous as "J. B. K." has suggested, it is a little strange that Messrs. Bagley's vegetables continue being held in such high esteem. Those celebrated growers use infinitely more manure than the "extravagant" quantities I have recommended, and I never knew the crops or ground poisoned, except on the sites of the Mushroom beds, and there, of course, the manure has lain 3 feet thick for six months. Not long ago I paid a visit to the "old school," and found them manuring as freely as ever. What does "J. B. K." say to upwards of 80 tons of dung per acre being used at one application? and yet Mr. Bagley assured me that they used half a ton to the rod (30½ square yards); in fact, I have seen them applying it at that rate. Why do they use it thus liberally? The answer is obvious, because it pays to do so, and yet the dung has to be purchased and carted six or seven miles. Soot is also freely used in the market grounds in addition to stable manure, and the condition of the crops tell how much they enjoy the rich food.

Instead of danger existing of poisoning the crops a greater danger by far is that of starving them, and I do not withdraw one word that I have written on the subject wherein "J. B. K." imagines I have erred so seriously.—A RETIRED GARDENER.

NOTES AND GLEANINGS.

THE GREAT INTERNATIONAL FRUIT AND FLOWER SHOW at Carlisle on 6th, 7th, and 8th of September. We are glad to learn that Lady Musgrave has increased the prize offered in the schedule for table decorations, and her ladyship will now present a cup valued at £25 to the successful competitor. The latest date for entries is now extended to the 30th of August, and a spirited competition is anticipated. Lady Musgrave, Eden Hall, and Lady Lawson, Brayton, have agreed to act as judges in this section.

A LETTER from Fulham informs us that there has not been such a good season for DWARF KIDNEY BEANS and SCARLET RUNNERS for ten years past. The market gardeners are receiving strong orders for the former, from the large pickle

manufacturers no doubt embracing the opportunity, as the quality may not be as good for some time to come. Vegetable Marrows are also a fine crop. Mr. Bagley's firm sent to market in one load about 4 tons on Saturday morning.

— WE have received the schedule of the twenty-second annual exhibition of fruit and cut flowers to be held at the CRYSTAL PALACE on September 21st and 22nd. There are twenty-six classes for fruit, ten for cut flowers, and two for vegetables. The chief prizes are £8, £6, and £4 for twelve dishes of fruit, and £6, £4, and £2 for a collection of vegetables. Besides good prizes being offered for Dahlias and Asters we are glad to find that encouragement is given to Gladioli growers, prizes of £3, £2, and £1 being offered to nurserymen for thirty-six spikes, and the same amount to amateurs for twenty-four spikes. Third prizes are provided in every class; and as the prizes are liberal without being extravagant, a good exhibition should result in a place where so many good displays have been seen in past years.

— THE annual Exhibition of the ISLE of THANET HORTICULTURAL ASSOCIATION is to be held this year on the 29th inst. by the kind permission of Latham Tomlin, Esq., in the grounds of Dane Court, St. Peter's, when upwards of 450 prizes will be competed for. A primary object of the Association is to encourage cottage gardening, and it receives the patronage of the Archbishop of Canterbury and many distinguished ladies and gentlemen of the district. C. D. Smith, Esq., 8, Marine Terrace, Margate, is the Hon. Secretary.

— A CORRESPONDENT forwards to us the following description of FRUIT-GROWING ON A RAILWAY EMBANKMENT in Brittany. "The whole of the usually waste ground by the sides of the line was planted with fruit trees, chiefly Pears and Apples. They were planted about 3 feet apart each way, each tree having two stems. One was bent to the right the other to the left, and when these limbs crossed each other they were tied together, so that the whole presented a continuous trellis of fruit trees, and as they were then (first week in May) in full blossom they added beauty to the scene."

— WE have received from Mr. P. Mitchell, Sydenham, a small case containing the COLORADO POTATO BEETLE in its various stages, modelled by Messrs. Stallwerck Brothers, Cologne, and for which Mr. Mitchell informs us he is the principal agent. The beetle is well shown, and the low price at which it is distributed places it within reach of all cultivators.

— THE Committee of the National Rose Society have determined on publishing a "ROSARIANS' YEAR BOOK," exclusively devoted to the Rose, and to contain a full report of their great show, critiques on new Roses, and other papers of interest connected with the queen of flowers.

— HORTICULTURE at the ANTIPODES would appear to be in a prosperous state, and a favourite pursuit of the well-to-do population, if we may judge from the copious catalogue of Messrs. Giles & Son of Magill, near Adelaide. This is a very full list of trees, shrubs, and plants. Amongst the latter are included the best varieties of Pelargoniums, Fuchsias, Dahlias, Clematises, &c., which are found in the lists of English nurserymen and florists. It is pleasant to notice this instance of antipodean enterprise, and the trade which evidently exists with the "mother country."

— A CORRESPONDENT of one of the daily newspapers recently observed that "it is probably not generally known that the region in which General Gourko has been lately operating with his Cossacks is the land whence by far the greatest quantity of ATTAR OF ROSES comes to western Europe. Kasanlik is the centre of one of the most remarkable species of horticulture, or rather agriculture, to be found in the whole world. Around it or near it are the districts of Cirpan, Giopça, Karadshah-Dagh, Kojun-Tepe, Jeni-Saghra, all of which are devoted to this peculiar husbandry. The Mussulman tradition assigns the origin of the Rose to the night of Mahomet's journey to Heaven. The white Roses sprang from the drops of sweat which fell from the forehead of the prophet himself in the toil-some ascent; the sweat of Borak, the miraculous animal he rode, gave birth to the yellow ones; while the celestial drops which fell from Gabriel were the source of the red Rose. Count von Moltke, who was well acquainted with Bulgaria and the Balkans, has styled the valley of the Tundja 'the Cashmere of Europe, the Turkish Gulistan, the land of Roses.' Roses are not grown there as with us in isolated patches in gardens, but in fields and in ridges, as if they were no better

than Potatoes. It would be difficult to imagine anything more charming than the appearance of those Rose fields, and any painter who should attempt to reproduce this picture would assuredly be charged with exaggeration; but it would be impossible to catch the infinite alternations of colour both among the Roses themselves and the green leaves of the shrubs. Hundred of millions of Rose leaves strew the ground, and are useless for the chief object in view. It is calculated that about one-fourth of the leaves are lost in this way; perhaps as much more either fail to come to the requisite perfection or are unavoidably wasted. The entire produce of the Tekne or region, of which Kasanlik is the centre, is estimated at between 800 and 900 kilogrammes (from 195 to 220 imperial gallons) of Rose oil. The wealth of water in the valley is prodigious; springs are not only numerous but most abundant in yield. There is a general system of irrigation which, remembering that the country is Bulgaria and not Lombardy, is admirable. The whole valley was a picture of prosperity, the result of natural fertility carefully tended by human industry. Where Roses are not cultivated heavy crops of Maize are gathered, and along the slopes and down by the waterside are numerous herds and flocks. Kasanlik itself is a town of 10,000 inhabitants, and is surrounded by magnificent Walnut woods, which also are a source of commercial industry.

— MESSRS. DICK RADCLIFFE & Co. have received a silver medal from the Cape Exhibition for seeds, and one also from Oporto for ferneries and aquariums.

— THE American "Gardener's Monthly" contains the following on wintering CAMELLIAS IN COLD FRAMES:—"We have here a few single-flowered Camellias, on account of our crowd of tropical plants are denied greenhouse space; hence we winter them in a deeply-sunk cold frame, which has no covering in winter beyond single sashes and single wooden shutters. These plants are not in pots or tubs, but each one has amassed a ball of roots. Late in April, or early in May, they are planted out, and on the approach of winter are lifted and heeled in the frame. As might be expected, they live unscathed, but this year each Camellia was as full of blooms as any specimen in Hovey's conservatory, and too, these blooms expanded fully, and were large and bright, and at their best in early May. Not a bud dropped."

— FINE SURFACE CULTIVATION is the secret to success in gardening. All good farmers know that it is the best means of successful cultivation in all of what are called the hoed crops of the farm. That it is so in garden culture must be plain to every intelligent man, since the seed of most garden crops are minute, and the plants themselves are, for a considerable time after germinating, delicate. The first requisite to success in gardening is, of course, a thoroughly rich soil; the next is drainage; the third is such surface culture as shall keep the plants growing as fast as possible. These are, in fact, three great points for successful cultivation with any crop, but especially so with those of the garden.—(*Prairie Farmer*.)

— IN many parts of India, says the *American Garden*, the flowers of a tree called *BASSIA LATIFOLIA* form a really important article of food. These blossoms, which are succulent and very numerous, fall at night in large quantities and are gathered early in the morning and eaten raw. They have a sweet but sickly taste and smell. They are also dried and stored as a staple article of food. A single tree will afford from 200 to 400 lbs. of flowers. These trees are of so much importance to the natives that when an invading force threatens to cut them down the threat generally insures the submission of the tribes. The blossoms of another species, *Bassia longifolia*, are used in a similar manner in Malabar and Coromandel. These are eaten either dried and roasted, or bruised to a jelly and boiled. The last are made into small balls, which are sold or exchanged for fish, rice, and various sorts of small grain. The seeds of all varieties of *Bassia* are no less useful than the flowers. Oil and soap are made from some, and from others a fatty substance called butter is extracted. This is of white colour, has an agreeable taste, and keeps well. It is an important article of commerce in Sierra Leone.

— MR. W. FALCONER writing in the American "Gardener's Monthly" on *BOUGAINVILLEA SPECTABILIS*, states, that "Although a native of tropical South America, this gorgeous climbing shrub feels quite at home with us in our Acacia house, which is an airy house with a winter night temperature of 38° to 42°. It is growing in a shallow tub, in a compost of

turfy loam with a little peat and leaf soil, and is trained up a pillar, thence along the top of the house. In summer we give it lots of water, but in winter keep it as dry as a Cactus. About the 10th of April its paniculate inflorescence and wealth of showy rose-coloured bracts become conspicuous and last all through May." We recently observed *B. glabra* in splendid condition in the greenhouse at Kew. It was planted-out and trained near the glass at the end of the house.

— A PROFESSOR of the Cornell University, N.Y., lately stated that Professor Buckman late of the Royal Agricultural College, Cirencester, in a prize essay on "Agricultural Weeds" enumerated 156 kinds in the cultivated lands of Great Britain, whence came most of the weeds that trouble the farmers in the United States and Canada. The number of seeds, says the American professor, produced by a perfect plant of the Dandelion is 2000; by the Ox-eye Daisy, 13,000; Dock, 13,000; Burdock, 24,000; May Weed, 40,000; Red Poppy, 50,000; Charlock, 4000; Wild Carrot and Wild Parosip, 1200 each, showing an increase from 1200 to 50,000 fold, while the cereals are set down from 20 to 300 fold.

— REFERRING to a note in our columns relative to the PHYLLOXERA, the American "Gardener's Monthly" dispels the idea that American Vines are Phylloxera-proof, but on the contrary states that "there is little doubt but the Phylloxera first appeared in the vicinity of Bordeaux, and was introduced by American Vines." Our contemporary further records that "Professor Planchon discovered that some American Grapes had a sort of contempt for the Phylloxera, while some—and all European Grapes—had their fibres injured by the insect. They gave up at once, as if asking, What's the use of resistance? But the Concord, Clinton, Norton's Virginia, and one or two others set to work and made more young roots at once, beating the Phylloxera by sheer perseverance." We do not dispute the correctness of that statement, but at the same time we cannot quite reconcile it with that portion of the report of the President of the Vine-growing Society of Pyrenees Orientales, which asserts that "each plantation of American Vines is the signal for a fresh invasion of the Phylloxera." It is just possible, however, that the American Vines are less vigorous in Europe than in their "own country," and which may account in a measure for the discrepancy alluded to.

THE ROSE YEAR.

WELL done, "PARSON'S GARDENER;" you had me there—you scored one in your last letter. I do not wish to stop your chucking at all, but feel obliged just to moderate it by telling you that since the Rose season commenced our drawing-room and our church have never been without Roses.

It is true that the Roses in my front garden were soon over, indeed my remarks in the Journal were not beyond the mark. But I am far too wise to carry all my eggs in one basket. I grow my Roses in all sorts of places, so when one part is quite done I have others to fall back upon. My front is one of the most sheltered and best situations you can possibly imagine, and there the Roses come and go very rapidly, but in other parts of my place I can keep-up a succession and shall not be without Roses of some kind till November. I have no glass wherein to prolong the blooming like my critic has, but without that aid I will back my Roses to last as long as even the older garden sorts of "A PARSON'S GARDENER."

But still my own idea so far agrees with his that I intend to make an alteration in my front, and not to devote the whole to exhibition Roses. I intend, however, to make an herbaceous border, and I do wish some of your staff or readers would give me, through the Journal, a list of herbaceous plants which must not be left out from it. The border is about 70 feet long and 5 broad, and the only plants I have at present are a few varieties of *Aquilegia*, *Iris*, and *Phlox*.—WYLD SAVAGE.

ROSE SHOWS IN SCOTLAND.—I read with attention "D. Deal's," report of the Galloway Rose Show, and was glad to hear that so much was thought of the Rose in Galloway as to induce them to have a special show for Roses. If the Gallowegians fancy they are at the top of the tree in regard to Rose-growing in Scotland, I hope they will now throw their competitions open at least to all Scotland, so that those who have not the privilege of residing in their little corner may have an opportunity of trying their mettle. I sincerely hope that next year we in Scotland may have an earlier and better season

for Roses than we have had this year. Except a few days in June it has been rain almost every day, and cold along with it.—A. A.

STRIPED QUARRENDEN APPLE.

WHEREVER ripe dessert Apples are wanted about the end of July and the beginning of August this variety should be grown. We have been using it for some time now in excellent condition. The fruit is about middle size, pale yellow, streaked with red outside, and white, juicy, and rich in the flesh. It is grown under several other names, as may be found in the last edition of Dr. Hogg's "Fruit Manual," which contains under the name of Margaret the following descriptive and historical account of this good Apple:—

"A first-rate early dessert Apple; it is ripe in the beginning of August, but does not keep long, being very liable to become mealy. To have it in perfection, it is well to gather it a few days before it ripens on the tree, and thereby secure its juicy and vinous flavour.

"The tree does not attain a large size, being rather a small grower. It is a good bearer, more so than the Joanneting, and is quite hardy, except in light soils, when it is liable to canker. It is well adapted for growing as dwarfs, either for potting or being trained as an espalier, when grafted on the Paradise or Pomme Paradis stock.

"This is a very old English Apple. It is without doubt the Margaret of Rea, Worlidge, Ray, and all our early pomologists except Miller; Mr. Lindley, however, is of a different opinion, for he believes the Margaret of Miller to be identical with that of Ray. That this variety is the Margaret of Rea, his description is sufficient evidence. 'The Margaret or Magdalen Apple is a fair and beautiful fruit, yellow, and thick striped with red, early ripe, of a delicate taste, sweet flavour, and best eaten off the tree.' Ray gives no description of it, but it is only reasonable to suppose that it is this variety he refers to, seeing it is the Margaret of all authors both immediately preceding and subsequent to him. And indeed in no instance is that of Miller noticed by any English author but himself anterior to Mr. Lindley."—A KITCHEN GARDENER.

OUR BORDER FLOWERS—LILYWORTS.

We have not a native representative of this charming order of plants. I wish we had. We have a plant bearing the name of Lancashire Bog Asphodel (*Narthecium*), but then it is not a Lilywort. As to their wherefrom, they reach us from many places far over the sea. The King's-spear Lilywort (*Asphodelus ramosus*) is from southern Europe, and has long been an occupant of our borders, but has not received that amount of attention it ought to have done. Truly it is a noble plant when established, and wants leaving alone. It is said to cover immense tracts of land where it is located, and affords good nourishment for sheep. It was sacred to Proserpine, and used at funeral ceremonies. *Asphodelus luteus* is most commonly met with, and when well cultivated is a very useful early and long-continuing border flower. *A. luteus flore-pleno* is a very desirable plant, and an improvement on the parent. *A. fistulosus*, said to be from France and Italy, is but very little known and seldom seen. Perhaps the least interesting of the family, yet useful for filling up spaces in waste or out-of-the-way places, is *A. creticus*. *A. capillaris* is one of the dwarfiest of the race, and ought to be much more cultivated than it is at present. There are other kinds that might be enumerated, but the foregoing are found in general cultivation.

They are not particular as to soil or situation, but are all the better for having liberal treatment afforded them. They enjoy light, and thrive well in ordinary garden soil mixed with sandy loam and well-decomposed vegetable matter. The spaces they are intended to occupy should be well broken up to the depth of 2 feet, and the above compost mixed with the soil. They are benefited by thorough drainage, and water when the weather becomes dry. If mulched they are all the better, and they require staking to prevent the wind from breaking them. They are increased by seed, but more easily by division, either in the autumn or early spring, when growth is commencing.

—VERITAS.

ROSES FROM CUTTINGS.

A FEW years ago I was persuaded to strike some Roses from cuttings. I did so, and was very successful, and I have been following the same plan every year since, without failure.

Early in October I procured some good cuttings, and cut them with a sharp knife and let them dry slightly at the ends, and planted them firmly in a bed of common garden soil mixed with a little old lime rubbish. The result has been that eight out of every ten cuttings have rooted. I have struck nearly all sorts up to the present time. As I notice you have had some inquiries from correspondents who want to increase their stock of Roses I advise them to try this simple plan.—S. J. W., Trowbridge.

IXORAS.

Few stove plants are more valuable both for exhibition and decorative purposes than *Ixoras*. As large specimens with rich deep green foliage and noble heads of flowers they have an imposing effect, while as smaller plants with from one to half a dozen trusses few plants can excel them during their period of flowering.

Ixoras are purely tropical plants, and the imported species are almost exclusively from tropical Asia. An Asiatic name has therefore been appropriately given to the genus, *Ixora* being a Malabar idol, to which the flowers of *Ixora stricta* (as

Fig. 30.—*Ixora* for decoration.

it was originally named, but now known as *coccinea*) are offered by the natives. This species is the first that was introduced to Europe nearly two hundred years ago, and it is popular and deservedly so, even when it has as rivals several beautiful garden hybrids which have recently been raised and distributed. *Ixoras* can be easily propagated by cuttings. Take a short-jointed half-ripened cutting about 6 inches long and insert it firmly in a small thumb pot in a compost of peat, leaf soil, a little fibrous loam, and a good admixture of silver sand. Plunge the cutting pots in bottom heat in a moist well-heated stove or propagating house, and not many days will elapse before roots are emitted. When these reach the sides of the pots transfer them to pots a little larger, and eventually into 48-sized pots, using the same sort of soil as described for the cuttings. Healthy plants in 5-inch pots are of great use for table decoration, while medium-sized plants with 6 or 7 trusses of flowers on them are very valuable for many purposes of decoration, as may be judged from the example shown in the accompanying illustration, fig. 30. The next shift should be into a 32-sized pot. Future shifts must be at the discretion of the grower, according to what size plants are required, but large shifts should never be given, which often result in sour soil and unhealthy plants. A little liquid manure may be given occasionally when the plants are established. Do not give the plants too much water in the winter time, and avoid drips from the roof, especially on such tender varieties as *Colei*, for drip at that period is fatal to good foliage. During the growing season afford plenty of heat and syringe twice a-day, the pots if possible being half plunged in a hotbed. Any shoots

threatening to steal strength from the others should also be stopped to give two or three shoots instead of one. If fly, or thrips, or bug appear there must be smoking and sponging at once.

This treatment should continue, with a little shade from very bright sun, until September. The pots should then be raised out of the hotbed, the plants placed nearer the glass and in full light; and though syringing may be resorted to at times, it

should gradually be discontinued, and water at the roots also lessened, but never so as to cause the plants to flag. The object is to ripen the shoots formed. During October and November the water must be lessened, and the temperature fall then and on to February to 60° and 55°, the roots just kept healthy and no more, and care taken of the leaves by syringing and sponging on a fine bright day. The rest is thus given at the dull season, as the flowers are much more pale when produced in

Fig. 31.—*IXORA REGINA*.

winter. About March, or earlier, the plants are to be moved into a higher temperature by degrees, and at first the pots partially and ultimately three parts plunged in a sweet hotbed, with openings below the pot to secure drainage. The temperature may be gradually raised to 75° and 80° with air, and of course waterings at the root will be more needed as the temperature rises, and the syringe must be pretty well used before the bloom trusses show. Then a drier atmosphere should be given and the plants be lifted out of the bed as the flowers open, and kept cooler and drier to preserve the bloom.

Ixoras cannot be grown in a low temperature. On this point a good authority has written as follows:—"I would particularly allude to this high temperature and moist atmosphere in summer as essential to success, as I have had several complaints that the *Ixoras* cannot be managed in a warm greenhouse temperature—about 50° in winter, and very airy in summer. It is waste of time attempting such plants under such

circumstances. I have given them up for a time because I have not enough heat for them. Those who can command a dryish atmosphere of from 55° to 65° in winter and a fermenting bed in spring and summer, securing a bottom heat of from 80° to 85° and 90°, and a top temperature of from 70° to 85°, and 5° to 10° more in sunshine, with abundance of atmospheric moisture, will no doubt succeed with these lovely plants, which are well deserving all such attention."

A few of the best varieties are *I. coccinea superba*, which still maintains its position as an exhibition plant; *I. Williamsii*, one of the very best of all, so free in flowering and has such large trusses; *I. Prince of Orange*, very distinct and fine; *I. floribunda nana*, valuable as a very free flowering variety in its young state; *I. Colei*, the best white; *I. Dixiana*, and *I. regina*. The last named is a new and splendid variety now being distributed by Mr. Bull, and of which the accompanying figure is a faithful representation. The plant is of dwarf floriferous

habit, the colour of the flowers being salmon suffused with violet. There are other very good and distinct sorts, which anyone can choose by looking at a trade catalogue.—D. L.

CAMPANULAS.

I READ with much interest Mr. Harding's article on Campanulas which appeared in your Journal a few weeks ago, and can fully endorse what he says respecting the usefulness and beauty of this class of plants, more especially some of the strong growers. I have tried one in particular, which pleased me and everyone who saw it. It is *C. Medium calycanthema*, blue and white. I sowed the seed about the middle of July last year, potted-off the seedlings, and grew them all through the autumn and winter, not letting them starve for want of pot room until they were potted into 11-inch pots about the end of March, using a compost of three parts good strong loam and one part good manure with a little sand. By the middle of June, when they commenced flowering, they made pyramids of 3 to 4 feet high, and 2 feet 6 inches in diameter at the base. They continued flowering until the last week of July. During that period I know of no plants more useful for halls, corridors, or the conservatory than these handsome Campanulas. They will propagate easily from eyes in the same manner as Hollyhocks are propagated in summer, which is a good plan for keeping the best varieties, as from seed a portion of the plants produce single flowers.—J. PITCHEES.

[We saw the Campanulas referred to, which were extremely effective.—EDS.]

TAKING UP AND STORING POTATOES.

MR. LUCKHURST, I must presume, is possessed of a sanguine temperament, which is perhaps inherent in a man of energy; and that he is a skilful cultivator and sound adviser none, I think, can doubt. A man who can laugh at the Potato disease, not only as affecting early varieties but also the main-crop sorts, must be listened to with respect on a subject on which he is so well able to speak.

As I have previously said, I have found no real difficulty in preserving my crops of early Potatoes from the murrain; but the late sorts, such as Paterson's Victorias and York Regents, have, I have always felt, been in a great measure beyond my control in the district of my experience. Mr. Luckhurst has made a worthy attempt to remove my difficulty on the early digging and thin storage question, but I am bound to state that his arguments lose force just in the ratio that they travel northwards. Your correspondent has in his last communication afforded tolerably good proof that cultivators on the Yorkshire flats and Lincolnshire levels have a difficulty to contend with that is much minimised, even if it is a difficulty at all, in the favoured vales of Sussex. I do not mean to suggest that no credit is due to a grower because he lives in Sussex and saves his crops; I only submit that the difficulty is so much the greater in saving the crops in a locality where they appear to be quite a fortnight later in ceasing swelling, and where the autumn rains do not postpone their visit until the Potatoes attain a marketable size.

According to the remarks on page 112 we may presume that Mr. Luckhurst's crop of Paterson's Victoria is lifted and stored. In that case he has almost certainly avoided the disease. But to have lifted the same variety in the locality where, I daresay, more Potatoes are grown in an area of five square miles than are produced in the entire county of Sussex, were to have secured a crop of "seed tubers" only, for by the second week in August they had not attained to a sufficient size for table use. That is the real difficulty—late ripening, and autumn rains occurring, not merely before the haulm has decayed but before the tubers of late sorts have ceased swelling. In the district to which I allude, unless sorts are grown which are ready for lifting before the grain harvest, it is practically impossible to give the necessary attention to securing them until the harvest is completed. Hence the safety of an important crop is unfortunately in a great degree a matter of chance: if the autumn proves fine all is well, but if wet much is lost. These remarks do not apply to a few sacks, or even to sufficient for the supply of one large family, but they apply to thousands of tons which are grown to feed the multitude of London, Manchester, Leeds, Bradford, and other large centres of hungry humanity.

But while I am conscious that the late ripening of the crops in the north is an impediment that does not occur to the same

extent in the south, I am also ready to admit that greater efforts should be made to save the crops, more enterprise should be exercised, and the habit of clinging to old customs should be relaxed to the securing of that important object. Hence I am glad that Mr. Luckhurst has endeavoured to show cause that his system is as applicable to Yorkshire as to Sussex, although he has not satisfied me on that point so well as he has satisfied himself. He has, however, made it plain that much may be done, and has given proof that many places—"gentlemen's places"—do not possess the conveniences desirable for making the best of a valuable crop.

That the crop of Potatoes is worthy of special care, even as well worthy of suitable storing houses as fruit is, I am quite convinced; but the difficulty is to convince others whose sanction is necessary for providing such proper means of storing the tubers. For years past I have given proof incontrovertible that Potatoes dug when the haulm is green and the skins not "set"—tubers which have just attained their full size but still unripe—ripen perfectly if properly stored, and become of equally good quality with tubers which had been left in the ground to ripen. I have also proved that the cropping quality of Potatoes so treated does not in the slightest degree deteriorate, because the same stock is fully as productive now as it was twenty years ago; yet notwithstanding I have never been favoured with suitable means of carrying out the practice on a scale commensurate with its importance, and have been obliged to make shift with such shelter as has happened to be within my reach; and I have often been obliged to see many tons of valuable food ruined when I have felt that much of the loss might have been averted by a different plan of treatment.

Leaving out altogether the question as to the period of taking up the tubers, immense loss is often incurred in the manner of storing. I am certain that if instead of the pernicious custom that is prevalent of placing the tubers in immense heaps to save covering material, if the necessary covering was liberally provided so that thin storing, at least for a time until the tubers were dry and carefully sorted, the gain would be great. It is of the greatest importance that the tubers should be stored dry and kept cool. Moisture and heat in combination are a primary source of disease. A large number of thatched hurdles or some such shelters, which would at the same time exclude wet and admit air, would be the means of saving much produce if the plan were carried out on an extensive scale, and the tubers were placed in narrow heaps or ridges.

It has frequently fallen to my lot to see Potatoes carted into immense heaps by the sides of stacks and buildings and covered with tarred rick cloths, and men, women, and boys have been engaged for weeks afterwards in "sorting" from a reeking mass of decay. How could it be otherwise? The moist tubers in such bulk could not fail to heat, and the cloths could not fail to prevent the heat escaping. Far better were it that the Potatoes were placed in thin narrow ridges, not wider at the base than the distance of a pair of cart wheels, and simply covered with straw, even if it did not exclude the wet. Provided Potatoes are kept cool, even if they are not dry, decay will not spread amongst them with a quarter of the virulence that it will in moist heated heaps. But covered hurdles placed over the Potatoes and not laid on them would be by far the preferable plan, and this suggestion of Mr. Luckhurst is well worthy of consideration; but the tubers of Paterson's Victoria do not cease swelling nearly so soon in Yorkshire as in Sussex, and immunity from disease in the north becomes proportionally lessened—all the more reason, your correspondent may suggest, that efforts to combat it should be the more determined and persistent.—A NORTHERN GARDENER.

AFTER the evidence given by Mr. Luckhurst on page 112, I think we cannot do wrong in lifting all varieties of Potatoes when the tubers cease swelling. On or about the 20th of July I began to think the crop was going, and having a special favourite among my exhibition sorts called Alpha, I lifted the entire row perfectly green, placing the tubers on shelves carefully. The skins were so tender they could scarcely be touched without rubbing them off. In three days the skin had set perfectly tight, and the tubers were firm, which gave me to understand that I had not done wrong. On the 6th of August I commenced in earnest, and lifted twelve varieties, consisting of Lord High Admiral and eleven other sorts, which may be termed second earlies. I never had a more happy day's work than in lifting these grand Potatoes, the rows of which were 30 yards long. There was not a speck of disease.

Among the most prolific is Early Vermont, which produced 14 stone per row; Porter's Excelsior, a grand Potato, 11 stone; Myatt's Kidney 9 stone. Next week I intend lifting King of the Earlies, Early Vermont, and others, although all the tops are green, and I would certainly advise all my friends to be up and doing, and try to preserve a crop, which is truly, as Mr. Luckhurst says, of national importance. One thing is next to certain, if the crops are left untouched until autumn the one-half at least will be lost.—R. GILBERT.

I CAN testify to the soundness of Mr. Luckhurst's remarks on the early lifting of the main crop of Potatoes. I think it behoves everyone who grows Potatoes to be on the alert and secure the crop, for from what I can hear and see many crops are becoming badly diseased in this county (Bedford). Both early and late kinds seem to be affected.

Perhaps it may be useful if I relate a case of early lifting of Potatoes in 1876. This was a plot of Regents. After a period of two or three weeks of hot dry weather the Potatoes in question were at a standstill, but after a fall of rain I could plainly see that a second growth was about to take place, so I determined on having the crop lifted, although the tops were as green as they well could be. Many people said that taking them up so early (July), with the haulm quite green and before the skins were set, was not the right thing to do. The skins may rub-off a little, but if they do they soon form another covering. The result of this early lifting was as follows:—The Potatoes were of medium size, and of good quality; in fact I could not wish for better quality, they were like balls of flour, and they remained so until the second week in July, 1877. I may remark that my neighbours who did not lift until late in the season lost more than half of their crops, and when planting-time came round some growers had not sufficient left for seed.

It is too common a practice when lifting late Potatoes to store them too thickly, whereby they become heated. They should be laid thinly and examined frequently. At the present time I am having all late Potatoes lifted as fast as possible with a view to saving them from disease, but owing to many men being in the harvest field I am having the tops pulled up and cleared away until such time as I can have the crop dug. The removal of the haulm will to some extent save the crop, even if the tubers are not taken-up for some little time to come.—G. R. A.

I QUITE agree with Mr. Luckhurst in raising Potatoes as soon as the tubers cease swelling. I once knew a farmer who dug-up all his Potatoes in August. The men employed were obliged to pick them all from the haulm. These Potatoes all kept well, but those left until the tops had died-down were scarcely half of them good. This is one instance out of twenty. We are taking-up our Victorias, Devon Reds, and Hundredfold Flukes.—J. P., *Devon*.

FALMOUTH FLOWER SHOW.

THE display, which was both extensive and attractive, was arranged in the Volunteer Drill Hall and a tent erected outside. Colonel Tremayne, the Rev. Thomas Phillpotts, Mr. M. H. Williams, Colonel Bull, and Mr. W. H. Lean exhibited large and beautiful collections of plants.

The Exhibition was very strong in high-class stove plants, the majority of which were sent not for competition. At the higher end of the hall nearly forty of the choicest specimens of the Carlews were effectually grouped by Mr. Palmer. Towering above all was a grand *Seaforthia elegans*, with other fine Palms extending on either hand. Striking objects in the centre were a large *Allamanda Hendersonii*, *Bougainvillea glabra*, and brilliantly coloured *Crotons*. The Rev. Thomas Phillpotts from Porthwidden sent an excellent collection, well arranged by Mr. Hogbin. The wealth of Pengerrick was exemplified in the best Gold and Silver Ferns in the hall, a good *Alsophila excelsa*, a *Gunnera scabra* with monster leaves and showing its curious fruit, and the freshest and largest *Todea superba* in the west of England. The cultivation exhibited in the collection was a credit to Mr. Thomas Evans, Mr. Fox's skilful gardener. Mr. M. H. Williams, Tredrea (gardener, Mr. Murton), was the only exhibitor of Orchids, and his specimens were greatly admired. Mr. W. H. Lean won close upon a dozen prizes, mostly firsts. In stove and greenhouse Ferns he ran Col. Bull very close, who exhibited the finest collection ever seen in the district.

The nurserymen supported the Exhibition admirably. Messrs. Curtis, Sandford, & Co. from the Devon Nursery, Torquay, sent twenty Roses, which had no difficulty in gaining the premier

prize. J. Hodge & Son, St. Anstell, had the best twelve Roses, and were placed first also for *Gladiolus*. Messrs. Mitchinson and Co. won the principal prizes for Dahlias, Asters, Cucumbers, collections of cut flowers, besides making a large display of blooms not for competition—Roses, Carnations, Geraniums, Fuchsias, Marigolds, Zinnias, &c.

The cottage gardeners made a capital display, the Cabbages and Onions being exceedingly fine. The small fruits were for the season good, particularly Red Currants. The Judges were:—For plants and cut flowers, the Hon. and Rev. J. T. Boscawen, Mr. W. N. Carne, and Mr. Marton (Tredrea), and Mr. Gill (Tremough). For cottagers' exhibits and fruit, Mr. Lobb (Devoran), Mr. Tyerman (Tregony), Mr. Hogbin (Porthwidden), and G. Palmer (Carlews).

PREPARATION OF FRUIT TREES FOR FORCING.

It is pretty well understood by those in charge of forcing houses that more depends on the treatment of fruit trees after the crop is gathered than on anything that can be done whilst the trees are actually carrying their crops. Especially are these remarks applicable in the case of Vines and other early-forced fruit trees, whose period of rest is, in the natural order of things, the time when root and branch should be in full activity and vigour. The different views held regarding the reciprocal action between root and branch at various stages of growth have long occupied considerable attention, and that is by no means so clear as it should be, if we may judge from the conflicting statements we read from time to time in the various horticultural journals. Whether the action of root and branch is simultaneous, or that the latter precedes the former, is to our own mind clear enough. It is fortunate that there is no dispute as to the union that exists between root and branch, and that we know that the one cannot exist without the other; and we think that the only rational view of the matter is that during the period of inactivity or rest the distribution of latent sap is less active, consequent on the want of propelling power after the fall of the leaf. What we wish to urge in the case of early-forced Vines and other trees is the difficulty to be encountered in working out, according to different circumstances, the natural growth inherent in each individual Vine or tree, and in settling how the future supplies encouraged by such growth are to be directed into the ordinary fruiting channels, and consolidated there in ample quantity to furnish food for the following season. We take it as an undisputed fact, that a Vine or Peach tree will yield fruit in proportion to the amount of healthy food that is concentrated in every individual bud and branch; therefore our efforts should be directed to the carrying-out of such measures as shall best attain the object we have in view. As before remarked, the great difficulty in this respect rests with very early-forced trees; for however unnatural it may be to change their winter into summer, they will yield submissively to the influence of heat and moisture; but it is quite another thing to impose upon them a season of perfect rest when the thermometer stands at 80° in the shade. From this point of view we regard the month of August as the most critical month of the year for early-forced trees. Vines are sometimes taken out of doors and covered with litter in order to retard them, and Peach trees may have the sashes removed from over them altogether; still there is the natural warmth and growth tending to excite against the unnatural remedies tending to retard. The one principle acts against the other, and the crops that follow are in proportion to the skill with which the two principles are managed. Vines, for instance, that are forced, however skilfully, to have ripe Grapes in March, become quite unmanageable in a few years, and will break away in the month of August, notwithstanding all the counteracting means that can be brought to bear upon them. Peach trees that ripen their crops early in May require careful watching lest the mild autumn weather should lead to premature excitement, which means the loss of all such buds as are unduly disturbed from their natural slumber before the proper time.

The principles laid down for our guidance in these matters are of such a nature that they cannot be applied to all cases alike; or perhaps we had better put it that the difference of circumstances renders the universal application of them impracticable. When early houses are so situated as to be influenced in some degree by their neighbours, such an arrangement aggravates the difficulty of inducing rest and consolidating growth. Warmed shallow borders, unless by the most complete arrangement in heating, are to be avoided as much as possible: the cure is worse than the disease, and of the two it

is sometimes the greater evil; for in order to avoid one extreme we are driven to another still greater. To escape the dilemma with anything like success a careful eye should be kept on the progress of root and branch towards maturity. Individual cases must be judged by their respective claims to our knowledge of their requirements. Healthy progress of root and branch will always go hand in hand. Healthy root-action, properly supplied from healthy sources, is sure to yield a healthy return in well-matured wood and leaves. Overfed or neglected trees are as easily distinguishable to the skilled cultivator as a declining patient is to a doctor. What we want is a full and natural season of growth; but we want the fruits of that growth properly directed and organised.

Vines and Peach trees require great supplies of water at certain times, but they also require that great discrimination shall be exercised in its administration. A Vine begins to make roots in earnest when the first tint of autumnal brown shows itself at the base of its young growth; and the supplies of water and other stimulants must be measured according to the health and age of the Vines, the condition of their roots, the state of the border they are growing in, &c., atmospheric moisture being supplied in moderate quantities at the same time. Borders are drenched, and Vines grow and swell and finish their crops; but is the benefit of all the labour entailed properly directed towards concentration, and do we organise all available strength as we should do into the fruiting spurs of another season? These questions are the great points of vital interest to be considered in preparing both root and branch for forcing. Worn-out Vines are often allowed to ramble as far and how they will in graceful pendant streamers. They have no tendency towards rectifying a disordered system or of centralising what little strength is left, nor will it add in any appreciable degree to the rooting power of the Vines for future crops—in fact, the contrary is our own opinion. We regard all growth except for fruiting purposes as superfluous, and superfluous growth we consider as over-taxation on an already enfeebled system. The Vine, being naturally of a travelling habit, will produce thickets of young wood annually; hence we see in many cases to what a mischievous extent attempts are made to combine the extension principle with a sort of semi-restrictive one. Young rods are encouraged to travel along the surface of inside borders, down back walls, or any other space at command where a young shoot can be encouraged, ostensibly for the best reason in the world—that of promoting vigorous root-action. Is this principle correct or not? and what facts have we to support it? Has the idea merely emanated from someone who may have succeeded beyond the region of his compeers, and ascribed his success to this principle of extension? We think the principle is deserving of no consideration whatever: it is mere conjecture, or something akin to it; its virtue is supposed to lie in its power to sustain and make roots. Well, but what about the ripening of them? We believe in the maturity of roots as well as of branches, and we can hardly strain our mind into the belief that growth made so far away from the influence of sun and light will ever mature roots that could survive the winter; and growth that is incapable of ripening its roots is practically valueless. And is it not also a gain to the Vine if by conserving wasted strength we can establish a more vigorous and fruit-producing power, and a tendency to health and longevity?

Our remarks are only intended to apply to certain modes of forcing, and to indicate how far we think certain means tend to recruit the failing power of trees which are supposed to have been reduced by early forcing and cropping. We say the full and natural development of all growth that can be exposed to thorough ripening influences is beneficial, and on the character that that growth may assume depends the future crop.

After the completion of natural growth the two main influences we have to study during the period of maturation are air and water; for heat we have the advantage of the all-powerful aid of the sun—a better agent than any artificial one we can employ.

Next to be considered is the co-operation of these influences; they must not be separated, but must work together towards one final end. Roots are formed according to the time and quantity of the feeding-power supplied, and if that be given in excess too late in the season the result will be the imperfect ripening of root and branch; whereas if the former is growing in a healthy border of adequate firmness and substance, and water is gradually withdrawn, a border will be secured of rich fibrous roots thoroughly ripened, which will serve as feeders

capable of supplying double the nourishment that could be expected from a less carefully prepared system of root-and-branch treatment.—W. HINDS (in *The Gardener*).

NOTES ON VILLA AND SUBURBAN GARDENING.

THE preparation of spring-flowering bedding plants should now occupy the attention of all who pride themselves on the gayness of their flower beds during the early spring months. Daisies, both the double white and pink varieties, bloom very early. They may be increased by offsets and dividing the roots. We generally divide and plant them at proper distances apart at the time of removing them from the beds in early summer, and they require very little more care than freeing them from weeds and occasionally watering; but where such has not been done, and they have been merely laid-in in masses, separate them at once and transplant from 4 to 6 inches apart. To perpetuate the different varieties of Pansies and Violas offsets and cuttings must be inserted now in a shady place. These are most useful for giving distinct lines of colour, and are very gay and free-blooming; but if distinctness is not required any quantity of plants may be raised from seed sown now. That pretty spring-flowering plant *Myosotis dissitiflora* is best raised annually from seed. Seedlings of it should now be transplanted, and old plants may also be divided; they then become sturdy and hardy to withstand the severity of the winter. Polyanthus in variety are also very gay, and from a packet of seed an immense number of varieties can be procured. Seedlings of these ought also to be transplanted now. The same remarks apply to Wallflowers, which are among the first plants to bloom in spring, and the perfume wafted in every direction by the wind is most delightful. They should be grown in all gardens and shrubberies. The plants ought now to be of good size, and be planted 9 inches apart in an open situation. The various kinds of *Silenes* should also be now sown. Beds of this annual when well massed together in the spring have a splendid effect. *Silene pendula* is the best for large beds, and the dwarf variety of it, *S. pendula compacta*, for small beds and pots. It is only by sowing early and having the plants strong that they flower sufficiently early to give place to summer bedding plants. The pretty annual *Collinsia bicolor* and other varieties of *Collinsia* are very desirable for spring flowering in herbaceous and mixed borders, as also are *Nemophila insignis*, *Saponaria calabrica*, and *Limnanthes Douglasii*. The *Saponaria* should be sown at once, the others towards the end of the month. The seed should be sown in drills a foot apart, and the seedlings be thinned out as soon as they can be handled. The plants then become sturdy and sufficiently hardy to endure ordinary winters. Golden Feather is sometimes used for colour, but it is not always to be depended on during the winter, though it is occasionally very bright and gay; the best plants are undoubtedly young seedlings. Many of the *Sedums* and the hardy *Sempervivums* used in summer carpet bedding can be used again in spring, and tasteful designs worked with them and spring-blooming plants.

Flower beds are now at their best. The carpet designs are well filled. All such that have a tendency to encroach on their neighbours must be pinched-in; bold but clear defined lines are necessary where designs are carried out. Go over beds of *Geraniums* and other flowers, and remove all faded flowers and set everything that may be out of place in proper trim, for neatness and compactness add much to the beauty of the flower garden.

"I cannot think what can be the matter with my Grapes; they were doing well, and all at once they appear to die off." Such are the expressions which have fallen from several of our amateur friends who have a small house or two and do not keep a gardener, but merely have "help" now and then. Nevertheless their small vineries afford them much pleasure and healthy exercise. From the description given to us of these Grapes we imagined they were scalded, and on inspection found it to be so. The very hot days we have occasionally had without sufficient air having been given early in the morning is the cause of it. With the houses closed up evaporation condenses on the bunches, and the berries become scalded. The only remedy now is to cut out all such with a pair of Grape scissors. Regulate the growths in these small houses, and do not let them become overcrowded or the wood will not ripen.

The work in the kitchen garden will principally be keeping down weeds and taking and storing Potatoes as they ripen, filling all ground as it becomes vacant with Coleworts, or sowing Turnips thereon if required. A sowing of Prickly or Winter Spinach should be made, and if Carrots are short a sowing of Early Horn or James's Intermediate will be found very useful for pulling while young. Celery will require attention; plenty of both clear and manure water is beneficial in promoting rapid growth. Some of the earlier-planted rows will require earthing. Tomatoes growing either in open beds or on walls must have the shoots stopped and thinned out. It is surprising how much more readily the fruit sets after all growths above the clusters

of bloom are pinched. Every facility should be given them to ripen their fruit before the dull days of autumn are upon us.—J. W. MOORMAN.

DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

KITCHEN GARDEN.

We have again during the week had genial showers, which have been a great boon to us, as the ground was very dry and hard, which made digging and trenching a work of some difficulty. The 8th of August is said to be the proper day to sow the early *Cabbage* seed, the produce of which will be ready to cut in May and June next year. Our own seeds were sown on that day, but it is quite ridiculous that any date should be chosen in preference to another within a week of the time. The seeds are sown on a piece of ground that does not receive much manure, and we like to sow thinly. We have tried many different varieties, but no sort succeeds so well as the dwarf form of Early York, seeds of which are saved in our own neighbourhood. A true stock of Enfield Market is very desirable, as it hearts later. This year Wheeler's Imperial has been sown for trial with the others. It does not say much for our progression in raising new sorts of Cabbage when this same Early York was grown fifty years ago.

It is as well to make two sowings of *Cauliflowers*, as it depends somewhat on the weather as to which will turn out the best. The first sowing with us will be made about the time this appears in print, and again in the last week of the month. It would be rash to say that the above dates are right for other portions of the British Isles; still we would not care to sow before the middle of the month unless it was a good way north, as the *Cauliflowers* are apt to button when the seeds are sown too early in the month.

As there is now plenty of spare ground it is a good time to make a sowing of Prickly *Spinach* for furnishing a supply during the winter months. We know that the best *Spinach* is produced on rich ground, but when this late crop is grown too strongly it is more apt to suffer from severe frost. It is well if possible to sow a reserve piece on ground that is not so rich. The best winter *Spinach* we ever saw was grown on a border facing south and sheltered in all directions from winds.

The market growers are very busy planting Coleworts, Sprouting Broccoli, and in some cases a late crop of Savoys. The recent rains have been very helpful to the planters. Plants that were set out about three or four weeks ago are much strengthened by having the hoe worked amongst the plants, and where the plants are sufficiently advanced the rows are earthed-up with the draw-hoe. A sowing of Parsley may be made for winter and spring use. It is also a good time to make a sowing of Turnips for winter use. The plan about here with the market growers is to run the cultivator over the Potato ground and then harrow it, sowing the seeds broadcast, harrowing again, and running a heavy roller over the ground. Those who delight in American Cress should now make a sowing on a border under a wall facing west; this will stand the winter well with a little protection, and will come in useful in the early spring months. We shall very soon sow the Paris White Cos Lettuce in the open ground in rows a foot apart. Some of the plants will be thinned out, and will be planted in another place, enough being left in the seed drills for a crop. As the crops of different vegetables are gathered see that the refuse is removed to the rubbish heap at once and the ground hoed, the weeds being burned or in some way destroyed; or the ground may be dug, the weeds and refuse being buried.

VINERIES.

The Lady Downe's Grapes in the late house are now colouring, and have passed the stage when scalding of the berries is to be feared. The house will now be kept rather closer, and a temperature of not less than 65° will be maintained at night. It is well to see that the Vines have a thorough watering with manure water just at this time, and the surface of the border should be kept damp by frequent sprinklings. We have insisted on plenty of ventilation and other details of the work quite recently. We are not much troubled with wasps and bluebottle flies in this neighbourhood, still they did us much damage one season, and we had a supply of medicated bags which were recommended very much at the time by some writers in the horticultural press, but the bags did more damage to the berries than the flies and wasps, by rubbing the bloom off the berries, and also causing many of them to be attacked by mould. It was therefore necessary to be continually removing the bags to get at the berries. We would never use such bags again; better by far is it to keep the insects out altogether, and this can easily be done by nailing some hexagon garden netting over the ventilators.

ORCHARD AND PEACH HOUSES.

We continue to syringe freely, and will do so until the first fruits are nearly ripe. The trees in pots receive large supplies of water at the roots, and it is necessary to make sure that the

Peach border has a thorough watering—enough to reach the roots at the bottom of the border. The treatment in all other respects is the same as that recommended for late Vines. Red spider will not do much harm until all the fruit has been gathered; but there is more danger in this respect than used to be the case when Royal George was the earliest Peach, the others succeeded it so rapidly. We shall discontinue growing Early Rivers; it is an early Peach, but more than half the fruits have invariably split stones, and nearly all of them decay before they are quite ripe. This sort requires peculiar treatment, and might be well grown in a house by itself. Hale's Early is the best early Peach, followed by Early York, both sorts introduced from America. A house of these two would be a good speculation for the London market. Early Grosse Mignonne is a grand sort to succeed them before Royal George comes in. As soon as the fruit is gathered the garden engine may be brought into play upon the leaves; it will soon rid them of spider, but will not thoroughly destroy the Peach aphid.

Strawberries.—It may be as well to state here that, although we were late with the runners this year, the plants are now put out in the open ground, and we are busy potting all those intended to fruit in pots. The pots are placed on a hard bottom, and are freely exposed to sun and air. In potting we use good loam and rich decayed manure, in the proportion of three to one. The compost is pressed firmly into the pots with a wooden rammer.

PLANT STOVES AND ORCHID HOUSES.

We have still a number of specimen plants and Ferns that require repotting. We have not yet been able to do all our work just when it ought to be done, but we hope to have all the large and small plants repotted within a week from this date.

Dipladenias have been potted, using very fibrous peat and a portion of clean silver sand to aid in keeping the compost open. Of all the flowering plants adapted for stove culture there are none to surpass these beautiful twiners. The only difficulty that we experience with them is that of keeping the house sufficiently warm where they are growing. The temperature during winter ought not to fall below 70° during the day, nor 60° to 65° at night. The best of the *Dipladenias* do not succeed in the lower temperature, which is suitable for most of our other stove plants. *Dipladenias* are very much subject to be attacked by scale, and, what is much worse, mealy bug. The plants do not require a very abundant supply of water at any time, but during the winter season very little suffices. In potting it is necessary to drain well, and to place some tough peat from which most of the fibre has been removed over the drainage. The finest species is *D. Brearleyana*, a garden hybrid between *D. crassinode* and *D. splendens*. *D. crassinode* itself is a very beautiful species; its flowers are rose-coloured, and are a sufficient contrast to the large rich crimson blooms of *D. Brearleyana*. *D. insignis* is similar in character to the latter, but the leaves and flowers partake more of the character of *D. crassinode*. Another beautiful species is found in *D. boliviense*, with its white flowers and yellow throat produced in rich profusion. *Clerodendrons* are making strong healthy growth, and the best treatment is to train the growths near the glass, where they will have an opportunity of ripening well before the dark days of winter. Rich sandy loam suits *C. Balfourianum*.

Gleichenia spelunca is a most elegant species of Fern, and it succeeds well with us in the warm end of a plant pit. The plants now require repotting; we shall pot them in turfy fibrous peat, and the pots will be half filled with drainage before potting, as the roots of these Ferns do not descend into the pot to a great distance. Other Ferns requiring repotting will also be attended to. *Adiantums* succeed best when the compost is principally good fibrous loam with just a little fibrous peat. Indeed, we have been most successful with the beautiful *A. farleyense* when the potting material has been all loam and a little decayed stable manure. We have not grown the elegant *A. gracillimum*, but it has been stated that this species does best with the same potting material. *Davallias*, *Dicksonias*, *Pteris*, and *Gymnogrammas*, indeed most other species, succeed well when loam and peat are used together in equal proportions.

In the Orchid houses most of the plants are at rest, and no more moisture is applied to the roots or in the atmosphere than is necessary to maintain the plants in good health. Both the cool and Cattleya houses have a temperature from 60° to 65° at night, with the ventilators open a little, and not any heat from the hot-water pipes; with a little heat from the pipes, and closing the house early, the temperature in the East India house is about 70° as a minimum.—J. DOUGLAS.

TRADE CATALOGUES RECEIVED.

Henry Cannell, The Nurseries, Swanley, Kent.—*Autumn Catalogue of Plants, Bulbs, and Strawberries*.

Giles & Son, Grove Hill Nursery, Magill, Adelaide, South Australia.—*General Catalogue of Trees, Plants, and Shrubs*.

TO CORRESPONDENTS.

CONTENTS (R. C. Pilling).—No doubt the suggestion you make would have its advantages, but we found that the demand for advertising space on the front page was so great that we were pressed to remove the contents to some other part of the paper.

PLANTS FOR A GRAVE (Constant Subscriber).—Plant Rosemary, "that's for remembrance," and the Pansy, "that's for thoughts." Then Forget-me-nots, Primroses, Daisies, and Snowdrops will furnish a pretty constant succession of bloom. Don't plant sad funeral Cypressos and Irish Yews; they do not remind us of "the life to come" as those lovely flowers do.

BEECH TREE DYING (X.).—The tree has probably been in failing health for some time although you have not noticed it. We can only attribute its injury and death to the wet subsoil, which is particularly inimical to the Beech; indeed, Brown in the "Forester" states that the tree will not live long under such conditions as those you name. Possibly the roots may be in a natural cavity in the impervious lias bed and so have suffered injury, while the other trees are apparently healthy.

POTATOES SHOWN AS A VEGETABLE (T. B. R.).—The Potato is undoubtedly a vegetable, and may be shown in a collection of vegetables.

VINES, &c. (Y. S. M.).—The Black Gibraltar is the same as Black Morocco. The leaf you have sent is probably that of Isabella from the description you give of the fruit. You will find a good treatise on Pine culture in "The Pine Apple Manual," published at our office, and sent free by post for 2s. 8d. Your *Lilium eximium* is quite correct. It is dwarter than *longiflorum*. We will give you some information on *Tropaeolum* next week.

HEATING SMALL GREENHOUSE (A. B.).—We do not think the two lamps would give off sufficient heat to keep out the frost from a house 12 feet by 6 feet. Why not have an ordinary stove and carry a pipe from it to the outside? The fumes from burning kerosene are as injurious as those from any other heating material.

PLANTS FOR THE FLOWER GARDEN IN WINTER AND SPRING (X. T.).—It is somewhat late for sowing seeds of some of the spring-flowering plants, especially the various kinds of *Myosotis* (Forget-me-not), which should be sown about the last week in June; a little seed might however be sown now, and if the autumn prove mild plants sufficiently strong to afford abundant flowers may be had. Sow now *Saponaria calabrica*, pink; *S. calabrica alba*, white; *Silene pendula*, pink, and *S. pendula alba*; *Alyssum maritimum*, white; *Nemophila insignis*, blue; *Candytuft* (Iberis), crimson, white, and purple; the red and white Virginian Stock, and the yellow-leaved *Præthrum*. When the seedlings are large enough to handle thin them, picking some of them out into nursery beds, transplanting them thence into the flower beds when the autumn flowers are removed.

GRAPES SCALDED (C. T. D.).—As Lady Downe's Seedling suffers so extensively every year, and the other Vines in the house are not injured, the best advice we can give you is to train up an additional cane from the best of the other sorts and remove the rod of Lady Downe's entirely. This variety is very prone to have its berries scalded. The cause of the injury is not so much in the border as in deficient ventilation. Scalding usually arises from air not being admitted sufficiently early in the morning. As you do not appear able to manage this variety we should cut it down and occupy the space with a rod from one of the other Vines. (W. S.).—Scalding of the berries results chiefly from a viney becoming unduly heated by the sun early in the morning before the moisture which has condensed on the berries during the night has evaporated. As a preventive of scalding, vineries should not be damped too late in the afternoon; a chink of ventilation should be left at the top of the house all night, and additional air should be given very early in the morning—the moment the thermometer in the house commences rising.

CUCUMBER FOR WINTER FORCING (Grains).—Telegraph is an excellent variety for growing during the winter. There must be no delay in sowing the seed or striking cuttings. Many growers fail by commencing too late. Smaller varieties, which are esteemed by many, are Lord Kenyon's Favourite and Munro's Duke of Edinburgh.

FUCHSIAS NOT THRIVING (A. R.).—We cannot account for the leaves and flower buds dropping off as they do, except that you probably have made the compost too rich, or they received a check in moving them from a Cucumber frame to a cool greenhouse. The best compost is turfy loam five parts, leaf soil one part, decayed manure one part, and sufficient sand to keep the compost open.

FIGS NOT SUCCEEDING (J. B. J.).—Figs never do well under the shade of Vines; and the fact that your first crop is good and the later crop indifferent suggests that the Vine leaves have an injurious effect as the shade becomes more dense.

CARRION IN VINE BORDER (Idem).—We fancy the Vine doing so well where the pigs are buried is not attributable to the pigs. You will not find any live roots amongst or near the carrion; the roots must have wandered somewhere else. Plant two Black Hamburg Vines in a border at the same time, treat both alike, and it does not follow that they will be the same two or three years hence; very likely the one may be much stronger than the other.

NEW AQUILEGIAS (M. R.).—*Aquilegia cærulea hybrida* and *A. californica hybrida* will probably be distributed by the Messrs. Veitch of Chelsea in the form of plants during the ensuing autumn. They have also a stock of *A. lepoceras lutea*, which is the same plant as *A. chrysantha*.

PROPAGATING REUS COTINUS (H. G. M.).—Layer the shoots at the present time, previously notching or tonguing them, and in due time they will emit roots. The flower sent may be one of *Lycasteria formosa*, but it is too fragmentary for us to decide with certainty.

WINTERING BEDDING PLANTS (N. J. M.).—If you will send a list of the plants you purpose preserving in cold frames we will state which of them we consider may be wintered in such structures.

SERVICE TREE (E. A. White).—You have been rightly informed that the fruit of this tree makes very good jam, but it is, of course, quite a matter of taste as to its equalling Guava jelly.

VEGETABLE MARROW FAILING.—ANTS (A New Subscriber).—The roots have probably penetrated the manure, and you water too much. Sprinkle guano over the nests of the ants, and repeat the sprinkling until they emigrate.

ROSES (Tyro).—It is very difficult to give reasons for the failure of certain plants when we have not seen those plants. Charles Lefebvre, Alfred Colomb, and Fisher Holmes are not good varieties for pot culture. Plant these in the open ground. This month is the best of all others for planting out Roses from pots. They get established before the winter. Peter Lawson is a small dark velvety Rose, and rather a weak grower. We do not know *Triomphe*

d'Amiens. Perhaps Rev. W. F. Radclyffe can describe it. *Blairii* No. 2 is not suitable for growing as a standard. It is a climber, and should be left like a Banksian to roam at will wherever and in any way it chooses.

AUTUMN-SOWN ONIONS FOR EXHIBITION (H. S. F.).—The seed should be sown the second or third week in August. The ground should be trenched 2 feet deep, or as deep as the soil will admit without bringing up any bad soil, though if the bottom soil be bad it is well to loosen it. A good manuring should be applied, mixing it well with the soil, the manure being thoroughly decomposed. The ground should be made firm, and the seed sown in drills a foot apart. When the plants have a pair of leaves thin to 2 inches distance apart, and keep clear of weeds, stirring the soil between the rows. To avoid the maggot, when the plants show the second leaf water overhead with paraffin water—a wineglassful to three gallons of water, stirring well up; let stand twelve hours, then stir again, and after standing another twelve hours skim off the oil from the surface, watering the plants with the clear or skimmed water only. This may be repeated in the early part of April, May, and June respectively. In March you may remove every three plants, leaving the fourth, planting them in well-manured deeply trenched ground in rows a foot apart, and 9 inches apart in the rows, the ground being well firmed before planting. All that is wanted is to water until established and to keep clear of weeds. A sprinkling of soot may be given every month, commencing with March and continuing until June, applying in such quantity as just to blacken the surface, applying guano between the soot applications at the rate of 2 lbs. to 30½ square yards, which will cause the manures to be applied at fortnightly intervals. If the weather be dry at the time of applying the manures they should be given in liquid instead of solid form—one peck of soot to thirty gallons of water, and 2 lbs. guano to the same quantity of water, the watering to be at the rate of one gallon per square yard. Sow Giant Rocca.

TACSONIA VAN-VOLKXEMI.—"Franklin" would be glad to be informed where he could see this climber flowering in the neighbourhood of London.

VEGETABLE MARROWS IN MARKET GARDENS (A. M.).—Holes are made to receive the manure, which is stable manure, or sometimes an admixture of stable and cow manure, and two plants are planted on each station.

CUCUMBERS DISEASED (C. W. Major).—The soil is too rich and too moist, and the temperature too low.

STRAWBERRIES WITH LEAVES CUT OFF (N. J. M.).—If the crowns are injured, the plants being young, they will soon form young leaves, and the plants will be none the worse on account of those they have lost. It is a practice with some persons to cut the leaves off with a scythe after fruiting, but we do not approve of the practice. You cannot do anything to help the plants.

PHYLOXERA ON VINES (Capt. Paul).—We have had rather too much experience with this pest, and are truly sorry to hear that it is widely distributed in the British Isles. It has twice appeared in our Vines, and each time it has been stamped out by destroying the Vines, root and branch, and carting away the soil where it could not do further harm. We advise you to do the same. As your Vines are young the loss will not be great. A friend of ours had it in a viney of young Vines. The *Phylloxera* appeared on one Vine in April; he thought it a pity to destroy all the Vines, and had the affected plant removed with all the soil in contact with its roots. The rest of the Vines grew well, and he was satisfied that he had destroyed the pest. However, early in the following year he thought he would examine the roots of the Vines, and to his surprise they were a moving mass of *Phylloxera*. This time he wisely destroyed the whole of the Vines, and truly glad he was that the pest did not spread to other houses a few score yards distance. We earnestly advise you to exterminate the pest by destroying the Vines.

DESTROYING WIREWORM (A. N.).—Dress the ground with gas lime, one peck (level measure) per square rod, distributing equally over the surface, it being best applied in autumn and forked in. The ground should be forked over again so soon in spring as the ground is in working order, and again before putting in the crop. It will drive them away if not destroy them. Many may be destroyed by baits of Carrots or Potatoes buried in the soil 1 to 2 inches deep, which should be examined daily, and the wireworms that have penetrated the baits destroyed, re-inserting them in the soil. If the baits have a stick thrust through them, so as to serve as a handle, they are more readily taken up and examined.

NAMES OF FRUITS (St. Bridged).—It is a difficult matter at any time to name Strawberries unless they are seen growing, but the three you sent were quite smashed, and therefore it was impossible to do so.

NAMES OF PLANTS (W. M.).—1 is *Cunninghamia lanceolata*; 2 we cannot name without seeing the flowers. Neither is hardy. (*B. Smyth*).—*Eccremocarpus scaber*. (*A. O.*)—*Lysimachia thyrsiflora*. (*J. P.*)—*Aloe variegata*.

POULTRY, BEE, AND PIGEON CHRONICLE.

A BATCH OF SCHEDULES.—PART 2.

WE have again received several schedules, some of them showing much improvement since last year and others none at all, while some are fresh in their new birth. Of the latter perhaps Ramsgate claims the earliest attention. Everything on the first page is "very swell." There are correspondents in Paris and Boulogne, there are to be especial boats from and to Boulogne, and a private wire will be laid into the Show yard. This is pretty fair for one page, but unfortunately the nominated Judges seem to have had the wrong duties allotted, for we find Mr. Esquilant put down for poultry and Messrs. Teebay and Hewitt down for the Pigeons. The other poultry Judge, Mr. Tegetmeier, is fully at home in either section. On the second page we find a noble President, seven lady patronesses, eight county patrons, and sixteen local ditto; and then on the next sheet we come to the rules—there are thirteen of them. Some of them are very much as usual, and others of a novel turn—e.g., Rule 4 tells us that the post-card which acknowledges the safe arrival of the entries will also admit the bearer free. This we entirely approve of, and consider a good rule and a saving of future trouble to both exhibitor and Secretary. Rule 5 tells us of an Hon. Sale-master, which we never remember to have seen before.

Rule 7 says all birds in the Sale classes must be in separate baskets, which is also thoughtful; but rule 8 is very important to exhibitors. We give it in full—"No third, fourth, fifth, or sixth prizes will be paid in classes in which there are less than six, eight, ten, or twelve entries respectively; and in classes in which more than two prizes are awarded to one exhibitor the two largest only will be paid, and when a cup is awarded the first money prize in the class will be withheld." The early part of this rule in our opinion takes off all the glory of the many prizes per class, and will prove a serious impediment, we fancy, to entries; and then finally a part of rule 11 is excellent—viz., "tops and backs of Game pens will be canvassed to prevent injury to the birds." We turn over the page and come to the classes. Partridge, White and Black Cochins all compete together, Game Bantams have one class only, Black Rose-combs none at all, and class 51 has a special cup given by Col. Shakespeare for the best pair of black-legged table fowls, which entirely upsets the world-wide-known fact that white legs should be aimed at for table chickens. There is a class too for Black Ducks, which will consequently include the Cayuga as well as the East Indians.

After this we come to a little Show which is to take place in connection with the Shirley (Southampton) Horticultural Society. This we hear is put out as a feeler to see if a show on a large scale would be supported at Southampton in the winter, and we should imagine it would. Chesham follows in a violet cover, which is rather a humdrum list, and only has the novelty of the Game being obliged to be undubbed. We come next to Aylesbury, which has had a total *bouleversement* in its classes. Unfortunately it clashes with Weymouth, Ipswich, and other shows, which with the new classification will not, we think, improve the entries. Single bird classes have come into operation here, and the Committee have been foolish enough to sweep away all the third prizes. The first prize now is only 30s., and the second 10s., and as the entry fee is still 5s. we cannot see much improvement. Pigeons and Canaries have been added, with a 15s. first prize and a 5s. second. On the whole we think the old schedules were much the best, and here is a case of so-called modern improvement without much chance of good results. Weymouth falls on the same day, and is a good schedule; but again the difference between the first and second prize is wholly disproportionate. The classes are numerous, the prizes are for chickens, and most varieties have classes for single birds. We only regret that Ipswich will clash, for though the latter schedule will probably be very good, Weymouth, Aylesbury, and others must injure the number of their entries.

Whitwick and Newbury again clash on August 21st. The former is a fair schedule, with classes for single birds of any age and some good local classes, which we highly approve of to increase the cultivation of birds in the district. Their Judges are Mr. E. Hutton and the Rev. J. F. Hodgson. Newbury is also much changed in its schedule. The first fourteen classes are now for old birds only, while chickens have seven classes. This Show is always well managed, and deserves support. Mr. W. J. Nicholls is to award the prizes, as he did at their last meeting.

Sandy holds its horticultural meeting and poultry show on the last day of this month. The classes are for chickens, which have four silver cups to compete for. There are 30 Vice-Presidents, 18 Committeemen, besides 43 district Committeemen, 2 Secretaries, and 870 subscribers. We heartily congratulate the Society, and shall expect to find next year an improved schedule as far as poultry are concerned. Next follows Henley-on-Thames, which is printed on a huge sheet, in the centre of which a Spanish cock, a Cochins cock, and a Dorking cock surrounded by Turkeys, Geese, and Pigeons, are apparently enjoying the most charming peace in the same farmyard. Would that our own cocks agreed so harmoniously as these appear to do. Mr. Nicholls here judges the poultry, and Mr. Baker of Kew Bridge the Pigeons. There are no Committee published in the schedule. The local prizes are fair, and we are told that they are confined to a circle of five miles, and that the winning pens of the first or second prizes are disqualified for the local prizes. The Northamptonshire Agricultural Society this year passes its boundaries, and meets in Leicestershire, at least we were taught that Market Harborough is in that county. The Committee comprise six well-known men, and the schedule is improved, inasmuch as three prizes are now given in all the classes. The Hon. Sec. still resides at Weedon, and is Mr. J. M. Lovell.

This ends our batch of schedules for this week. More will be noticed in due time, and the next batch will probably comprise many famous shows which are soon coming on in the metropolis and elsewhere. We wish the managers of shows would try to study each other's interests more, as the present plan of three or four of our best shows in one week must prove disastrous to one or two of them.—W.

MALTON POULTRY, &c., SHOW.

This Exhibition was held on the 9th inst. in the Lodge Grounds by the kind permission of Capt. Copperthwaite. The

schedule was well arranged, for the classes were numerous, though the prizes were not very large; but the entry fee was a low one. There were classes for *Silkie*s and *Cayuga Ducks*, which are not generally found in most schedules. Mr. Dixon awarded the prizes, with help from Messrs. Ferguson and Temple, and their awards were well received. The *Hamburghs* were of excellent quality, Mr. Beldon's Golden-spangled hen being of good quality, as too were the first *Silver-pencils*. Buff *Cochins* were very good, the prize pens of Mr. Sidgwick and Mr. Proctor were of much merit. A good pen of *Houdans* won also in their class, and the prize *Polands* were of great quality. The first-prize pen of *Silkie*s were well clawed, and the hen had a large crest, but being adult birds were a little out of feather. The winning Game *Bantams* were capital birds, shown in fresh condition and smart in carriage. There was a class for chickens of the year, but there had to be three birds in a pen, which rather militated perhaps against the number of entries. The *Waterfowl* were excellent. The first *Aylesburys* clear in bill and large in size. *Geese*, too, and *Turkeys* made a fine display. There was, moreover, an excellent class of *Guinea Fowls*.

The *Pigeons* were the most noticeable for the ample classes which were furnished, there being classes for Spots, Nuns, Archangels, Trumpeters, &c., in addition to the ordinary classes for the more cultivated breeds.

There were also six classes for *Rabbits*, where the competition was large for the prize money offered, and the quality good. These were judged by Mr. Lamb. We furnish the list of poultry awards below.

POULTRY.—GAME.—*Black Red*.—1, W. Rudd. 2, E. Wharton. *Brown Red*.—1, W. Rudd. 2, J. Cass. *Any other variety*.—1, W. Rudd. 2, J. E. Crofts. *SPANISH*.—1, J. Hwesh. 2, J. Powell. *HAMBURGH*.—*Gold-spangled*.—1, H. Beldon. 2, Holmes & Destner. *Silver-spangled*.—1, Fawcett & Anderton. 2, G. Waite. *Gold-pencilled*.—1, H. Beldon. 2, G. Snell. *Silver-pencilled*.—1, E. Snell. 2, G. Waite. *BRAMA*.—*Dark*.—1, G. W. Henshall. 2, H. Beldon. *Light*.—1, G. Pounder. 2, J. Birch, jun. *COCHINS*.—*Buff or Cinnamon*.—1, G. H. S. Rawson. 2, C. Sidgwick. *Any other variety*.—1, G. H. S. Rawson. 2, G. W. Henshall. 3, F. H. Stericker. *CREVE-CEUR*.—1, O. E. Wise. 2, J. Mackwell. *POLANDS*.—1 and 2, H. Beldon. *FARMYARD CROSS*.—1, G. Robinson. 2, A. Russell. *CHICKENS*.—1, G. Garbutt. 2, T. Greenhalgh. *SILKIES*.—1, Rev. R. S. S. Woodgate. 2, Master R. L. Russell. *BANTAMS*.—*Game*.—1 and 2, W. F. Entwistle. *Any other variety*.—1, H. Beldon. 2, H. Hainsshaw. *ANY OTHER VARIETY*.—*Chickens*.—1, C. Sidgwick. 2, R. P. Hockley. *GUINEA FOWLS*.—1, F. G. S. Rawson. 2, Holmes & Destner. *DUCKS*.—*Rouen*.—1, F. G. S. Rawson. 2, G. Garbutt. *Aylesbury*.—1 and 2, E. Snell. 3 and 4, T. Sody. *CAYUGA*.—1 and 2, Mrs. Coulson. 3, T. Pierson. 4, W. Marshall. *Any other variety*.—1, T. P. Carver. 2, T. H. Chambers. *GEESSE*.—1, G. Pounder. 2, F. G. S. Rawson. 3, Miss Watson. 4, E. Snell. *TURKEYS*.—1, J. Moorey. 2, F. G. S. Rawson. 3, Mrs. Jordan. 4, Mrs. Harriman. *SELLING CLASS*.—1, J. Cass. 2, J. Newall.

DRIGHLINGTON POULTRY SHOW.

THE annual Show was held at Drighlington on the 12th inst. Turner's pens were used, and arranged in the open air. In numbers the entries were very good. In poultry *Spanish* headed the classes with good pens, the first old and second chickens, *Dorkings* being placed in the same position. *Cochins* and *Brahmas* were very good in both cases. *Game* were not as numerous as we have often found them here. In the first class *Brown Reds* were first and *Black Reds* second. The best cock was in pen 1, but the hen was badly duckfooted. In the next two classes *Duckwings* and *Piles* won the prizes. *Hamburghs* were poorly represented as to numbers, but were very good. In *Game Bantams* first were a pair of *Duckwings* and second *Pile* chickens, and in the *Variety* class *Black* and *Silver Sebrights* won. *Geese* were a splendid class; the whole were *Toulouse*, and every pen very large and good; the *Ducks* in all the classes being better than ever we have found them in this quarter, which boasts of its aquatic birds.

Pigeons.—In *Carriers* first was a *Black Hen*, recently hurt and bleeding much, but far a-head of the rest. *Pouters*.—*Blue* first and *Whites* second. *Almonds* third. *Any other Tumblers*.—First a *Short-faced Blue Bald*, second an *Agate*; and there were some capital *Black Baldpates*. In *Barbs* first was a *Yellow* cock and second a *Black*. Antwerps a moderate class, a handsome *Dun Short-face* being put first. In *Turbits* the first was not in good feather, but was a grand *Blue*, and second a *Red* hen. *Jacobins* good, two *Reds* winning. *Owls* were but poor. In the *Variety* class first was a *Fancy Swallow*, second a *Red Magpie*, and third a *Blue Dragon*.

A few *Rabbits* were exhibited, but the prizes were poor in these classes. *Himalayans* a moderate lot. The *Variety* class was a very good one. The first, a *Silver Cream*, was excellent; extra first an *Angora*, second a *Silver-Grey*, and extra second a *Black Dutch*.

POULTRY.—*SPANISH*.—1 and 2, J. Powell. *DORKINGS*.—1, J. A. Walker. 2, J. Rawnsley. *COCHIN-CHINA*.—1, J. A. Walker. 2, C. Sedgwick. *BRAMA*.—*Pootra*.—1 and 2, W. Schofield. *Any other variety*.—1, J. A. Walker. *GAME*.—*Black-breasted* or *other Red*.—1, W. Schofield. 2, H. C. Mason. *Duckwinged*.—1 and 2, W. J. Mason. *Any other variety*.—1, E. Walker. 2, J. J. Mason. *HAMBURGH*.—*Golden-spangled* or *Silver-spangled*.—1 and 2, J. Rawnsley. *Gold-pencilled* or *Silver-pencilled*.—1 and 2, J. Rawnsley. *Black*.—1, J. Rawnsley. 2, C. Sedgwick. *ANY OTHER VARIETY*.—1 and 2, J. Rawnsley. *SELLING CLASS*.—1 and 2, J. Rawnsley. *BANTAMS*.—*Game*.—1, F. Holt. 2, R. Swales. *Any other variety*.—1, J. Grashon. 2, J. F. Crowther. *GEESSE*.—1, J. A. Walker. 2, J. F. Crowther. *Any other variety*.—1, J. A. Walker. 2, J. F. Crowther. *DUCKS*.—*Aylesbury*.—1 and 2, J. A. Walker. *Rouen*.—1, J. J. Pollard. 2, J. Newton. *Any other variety*.—1 and 2, J. A. Walker. *PIGEONS*.—*CARRIERS*.—*Cock or Hen*.—1, J. Booth. 2, J. E. Crofts. *POUTERS*.—*Cock or Hen*.—1 and 2, J. E. Crofts. *TUMBLERS*.—*Almond*.—*Cock or Hen*.—

J. E. Crofts. 2, G. S. Burton. *Any other variety.*—Cock or Hen.—1, B. Rawnsley. *vhc*, J. Oldfield (2), J. Thresh, G. S. Burton. *BARBS.*—Cock or Hen.—1, W. Rudd. 2, J. Thresh. *vhc*, J. E. Crofts. *ANTWERPS.*—Cock or Hen.—1, W. Firth. 2, T. Milner. *vhc*, W. Rudd, B. Rawnsley, W. Firth. *TURBITS.*—Cock or Hen.—1, W. Rudd. 2, T. E. Hainsworth. *vhc*, W. Rudd, G. S. Burton, T. Milner, B. Rawnsley. *FANTALS.*—Cock or Hen.—1 and 2, T. E. Hainsworth. *JACOBS.*—Cock or Hen.—1, J. E. Crofts. 2, G. S. Burton. *vhc*, B. Rawnsley (2). *TRUMPETERS.*—Cock or Hen.—1, J. E. Crofts. *MAGPIE OR SWALLOW.*—Cock or Hen.—1 and 2, J. E. Crofts. *WILD.*—1 and 2, J. E. Crofts. *OWLS.*—1, J. Thresh. 2, T. E. Hainsworth. *ANY OTHER VARIETY.*—Cock or Hen.—1, J. E. Crofts. 2, W. Rudd (2).
RABBITS.—*LOP-EARED.*—Buck or Doe.—1 and 2, R. Murgatroyd. *HIMALAYAN.*—Buck or Doe.—1, T. Hart. 2, R. Murgatroyd. *ANY OTHER VARIETY.*—Buck or Doe.—1, J. Firth. 1 and 2, Burton. 2, W. Wailes. *vhc*, J. Firth, R. Murgatroyd. *Point Prize*, J. E. Crofts.
CATS.—Male or Female.—1, S. A. Bell. 2, J. Cooper.

JUDGE.—Mr. E. Hutton.

THE LOP-EARED RABBIT.

THERE are several theories as to the origin of this the king of the Rabbit tribe. The two most probable are, that it is a native of Persia and has been imported into this country, and that it is merely an improved strain of the common Prick-eared Rabbit. We are inclined to the former idea, although there is no doubt that it has been greatly improved in this country, as shown by the fact that a few years ago 22 inches across the ear was considered excellent, and 23 impossible, and that now 23

from tip to tip was at one time—not many years ago—thought excellent, and anything over 21 very good. Now 22 and 22½ are thought decidedly good, and 23 and upwards first-rate. Twenty-three and three-quarters and 23½ are about the best lengths at present being shown. We remember seeing at a show in the neighbourhood of the Edgware Road, a gallant Lop 24 and, we think, one-eighth, in length. The Rabbit was certainly a beauty, but the measuring was a little strong, as the Rabbit, if shown since, has certainly not been credited with such prodigiousness. Still the length was, no doubt, 24 inches, and if we recollect another was shown in the opposite corner of London about the same length a few months afterwards. These figures show plainly that very rapid strides have been made in this particular. Length, however, is not all. Breadth must also be looked to, and although an improvement has certainly taken place lately, no such rapid strides have been taken as have been done in the length. The quality of the flesh of the ear should be very fine and thin. The outside of the sheets, for they can be called nothing else, are covered with a meagre covering of short hair, but the inside is quite devoid of hairiness, the skin being clean and smooth, only disturbed by the veins which course down and in which the pink of the blood can be plainly discerned. The fall or carriage of the ear used to be a question of vast importance, as indeed it is now, only that the enormous weight generally drags them down into the correct position or something like it. They

Fig. 32.—THE LOP-EARED RABBIT.

and a fraction is common, and 24 has been managed two or three times.

The points of the Lop are very easily described, although they are not so easily attained. We will take a full-grown specimen and run through its points, afterwards dealing with colour and markings.

The body should be firm and strongly set, with a decided fall at the shoulder and rise at the hip, so that when an animal is in a reclining position the hinder portions of the back are much higher than the head. The "carriage" of a Rabbit depends to a great extent upon its deportment in this respect, a long-bodied and flat-backed specimen being considered decidedly inferior. The hind legs should be long and bony and nearly twice as long as the front ones. These latter should in youthful animals be straight and nearly parallel, although if they are a little banded in an old and well-fleshed specimen, it is, perhaps, not a great drawback. The legs should, however, be straight when young or not fleshy, any crookedness being a decided disadvantage.

The head should be of good size and the forehead prominent, the eyes set well apart, and the nose fairly pointed. The eye should be firm, full, and well set. The colour will be dark, brown, or blue, the latter being, perhaps, the most common.

The ear is the most important organ of the Lop, and hence it has been more or less tampered with from time to time—stretching, pulling, and working having been all called into use at one time or another, but with very little effect. It is certain that if the ears of a half-grown Rabbit be worked carefully and regularly before a steady fire the effect will be to slightly lengthen them; but the best specimens shown are those that have long, broad, and natural ears, and not long and narrow. The first point of excellence is in the length. As already stated, 22 inches

should fall well from the roots, and be of equal declension on both sides. The inside of the ear should fall towards the cheek, leaving the outside or the hairy portion only visible when standing in front. The great length of the ears generally causes them to drag a little on the ground, causing them to be drawn a little out of the correct position and causing the ends to be bent back. The chest of a good well-conditioned Lop is full and prominent, something like that of a Pouter cock, and the skin being loose and so full of fat that it causes a perfect resting place for the chin, and adds materially to the animal's appearance. It is called the dewlap. It seldom makes its appearance till after the Rabbit is a twelvemonth old, or quite full-grown. Other positions of the ear beside the full lop used to be known and to give trouble, including the horn lop, in which case the ears fell over the face in a most unsightly manner, almost blinding the animal and presenting anything but a pretty appearance. Scarcity generally conduces to value, but in this case, although the appearance was very rare, it has never been liked. Another appearance was the half-lop, which was divided into two kinds, and one in which the ears both fell on one side of the neck, and the other in which one ear fell and the other stood erect. Another position was the ear-lop, in which case the muscles of the ears were too strong to allow them to fall, and then stood out on either side of the head like the ears of a boat. This last form was very common, and is often found in bucks of considerable physical power.

Colour is an important feature of the Lop. If a self-colour, it is purely a question of taste whether black, blue, grey, fawn, or white is liked the best. Grey used to be disliked very much, but fanciers are not so fastidious now-a-days, and if a Rabbit's points are otherwise good, a little fall-off in the respect of taste

will be allowed to go by unchallenged. If a broken-coloured, the back or saddle should be wholly of the dark colour without any white hairs. The head should be pretty dark, and the ears quite so. The markings of the head, as of the body, should be regular, and sometimes the face presents a very pretty appearance. The various forms of smuts are all pretty, but the butterfly smut is the prettiest of all. At one time the head markings were thought a great deal of, but now all has given way to the ear rage.

The Lop is not very prolific, nor is the doe quite as good a mother as some of the other breeds; hence nurse does are generally used, Dutch being the commonest and the best. In disposition they are a little spiteful often, and are not very good pets. As they are very delicate and require a great deal of extra care, they are not the best breeds to begin with.—GETA.

FANCY PIGEONS AT THE BRITISH MUSEUM.

WHEN recently in London I went to the British Museum to inspect the new acquisitions in sculpture from Ephesus, and having gazed my fill upon the wonderful chiselled stones of the temple of the great goddess Diana, which not only St. Paul might have seen but must have seen, I not unnaturally took a turn among the stuffed birds, admiring the admirable manner in which they are "set-up"—so life-like, so true to nature as eye and attitude; particularly is this the case with the Raptores. Along the wall the specimens are wonderful, but perhaps the very best and most striking is the Eagle Owl or great Horned Owl, which stands out clear towards the centre of the room. The bird is standing in the attitude of anger or combat, almost every feather separated and erect. This is a marvel in the art of taxidermy. Going on further I sought out the Columbidae, and the foreign varieties are excellent, but on searching for the English fancy Pigeons I was grievously disappointed. Up in a corner, high up and not easy to see, are a group of mere objects—bad specimens of fancy Pigeons to begin with, birds that would never take a prize in the smallest show. Then, in addition, they are wretchedly stuffed, evidently by an artist in taxidermy who had no idea of the points of fancy Pigeons. Their condition is not good either. They more resemble the class of stuffed birds one sometimes sees at a country auction. Apparently they are very old as well as very inferior, and wholly unworthy a place in our great imperial, for it is more than national, for it is not the English but the British Museum. I saw a red Jacobin, long-beaked and badly filled, with wrong eyes and the not only low cut—that might not be objected to by some—but with a dash of white going down the neck. A strange-looking bird is marked as "a Horseman." There are Tumblers not Tumbler-shaped; indeed, the whole group, happily half hidden in a corner, are unworthy of their names and place. Now that we have more than one admirable Pigeon artist it would be easy surely to stuff birds according to the pictures given by Mr. Harrison Weir or Mr. Ludlow. I think it is a matter of much regret that fancy Pigeons should be so badly represented in the British Museum. The ornithological authorities cannot be ignorant that at the Crystal Palace there have been for years exhibitions of fancy Pigeons of singular beauty of form and feather, and while the Museum gathers the best of all kinds and varieties of birds, it is hardly right therefore that so beautiful a class should be so miserably represented, and that the British Museum should be so behindhand. These specimens were collected probably in days when a Jacobin was a Jacobin and that was all, and few cared or knew about superior specimens or in what superiority consisted. Now it is all altered, and I should like that admirers of Pigeons should be able to go to the Museum to see good birds properly "set up." There would be no difficulty, for the very best Pigeons are from their delicacy frequently dying, and their skins could be procured.

As a contrast to the stationariness of the British Museum I must notice the advance of the London bird shops. I took a stroll through the Seven Dials and some other localities where Pigeon shops are to be met with. In most of these there is a marked improvement upon the mongrels formerly to be seen. Even fair Pouters are in cages for sale. Evidently the sweepings of good lofts come into the bird-dealers' hands now, and not merely birds to be sold so much a dozen as Blue Rocks. The mark of progress in the fancy is shown now very generally in both London and provincial bird shops. Better poultry, often capital Bantams, Pigeons of a higher class, and Canaries much superior to the very common sorts seen in dozens in former years. I can only hope that improvement will in due time reach the British Museum.—WILTSHIRE RECTOR.

APIARIAN EXPERIENCES IN 1877.—No. 2.

I FORGOT to mention that I had given the bees of my strong stock five sectional supers (Abbott's pattern) about the 16th of May, in the hope that they would fill it with apple-blossom honey. They took to it in force, almost occupying its whole length; but, owing to the wretchedness of the weather, all they

did was to make two small bits of comb up to the time of their swarming on the 31st. I then took off these sections and gave them to another hive, where again I was disappointed, as the bees swarmed and no honey was to be had, the cells being merely enlarged somewhat, then filled and emptied by the bees themselves. So I fear that I shall have no experience to report with regard to sectional supers this year. I see in my notebook a entry at that date in the following terms:—"Never knew so poor a year for honey. Not a single pound visible anywhere. Still feeding two stocks."

My next strongest stock swarmed on the 8th of June, by which time the weather had much improved, and almost a glut of honey followed, but only for a few days. This swarm (alluded to before) behaved strangely; first trying to get into an empty hive adjoining, which had some clean comb ready for use, but many of the bees entered the hive below, out of which came a swarm of May 31st. Then trying to settle on an Apple tree, they finally returned to their own hive, but in considerably diminished numbers. It became evident by the hive piping before the re-issue of this swarm on the 18th of June that they had lost their queen during their first attempt. As I said before, my belief is that at that time their queen entered the hive below and perished there. Be this as it may, the swarm again returned home, their instinct leading them to prefer a well-filled hive to the chances of starvation at a separate establishment in so unpromising a season, for by this time all honey-gathering had ceased again. Fearing this result, and wishing to increase my number of hives, as soon as they had re-entered the parent stock I drove out the whole available population and made a strong swarm thereof, hiving them in one of my largest hive boxes. This was put in the place of the parent stock, which I shifted to another part of the garden. Of course there was an abundance of brood coming on, and several royal cells in every stage of development. When I left home on the 9th of July these bees, both swarm and parent stock, were doing as well as the circumstances of the bad season would allow.

On the 22nd of June—expecting a strong stock of black bees to swarm which had partially filled a small super, and wishing to substitute a half-bred Italian princess for their own queen—I drove out the whole population, killed their black queen on the spot, and hived them in a Woodbury bar-framed hive. This had been prepared beforehand by adjustment within the frames of several combs of pure Italian brood taken out of a weak stock whose queen had been imported by me last September. On the same day I had previously driven the pure Italian bees with their queen into a temporary box, but I subsequently turned them into the hive out of which I had driven the black bees. I thus gained a double object, italianising a common English stock and strengthening a weak Italian one.

With regard to the Woodbury, I have to remark that on examining it on the 4th of July I saw a beautiful Italian princess (very lively) perambulating the combs; she was therefore but twelve days exactly in being reared, and the bees can have lost not a moment of time in replacing their old queen.

My last operation before leaving home on the 23rd of June was similar to that just described. My sole remaining stock of black bees was deprived of its queen and made to change hives with a weak hive of hybrid Italians which had just reared a prolific young queen.—B. & W.

PLEASURES AND PROFITS OF BEE-KEEPING.

SOME people keep bees for pleasure, some for profit, and some for both. In some instances pleasure and profit are bound together and go hand-in-hand. I keep bees for profit, and in doing so derive a large measure of enjoyment. Bee-keepers with open eyes and ears have grand times amongst their bees. How often a stroll through the apiary drives "dull care away." What lessons of contentment and unity, fraternity and equality, industry and cleanliness, may be learned from bees. How many hundreds and thousands of times have I after nightfall placed and gently pressed my ear against the sides of hives to listen to the wonderful hum inside. What a wonderful buzz is there heard night and day continually. It is a hum of commotion and concord, of health and activity. No sound of discord, no jarring note is heard in any part of a bee hive. Bees have not time to grumble, nor occasion for grumbling, as every inmate of a hive works willingly and unerringly. Injustice and wrong-doing find no place in a bee hive. Magistrates and authority of all kinds are unnecessary. All the working inhabitants are free-born citizens with unfailing courage and loyalty. While human beings lock their doors and go to bed, and while the millioned city of London is lulled into quiet for a few hours after midnight, the hum of a bee hive goes on unceasingly.

And what real enjoyment the bee-keeper has from seeing his favourites at work outside carrying home water for the day before honey can be had, before the dew evaporates, in seeing them afterwards going off in continuous streams to the fields and returning with heavy loads of pollen and honey, in witnessing the expansion of the city by comb-building, the increase of popu-

lation by breeding, the swarming of bees, the multiplication of stocks, and the signs or prospects of a harvest of honey! What real and inexpressible enjoyment have we seen marking the faces of working people, both husbands and wives, at harvest time when they have had a great take of honey! Good hives and good harvests buy golden nuggets, and golden nuggets help to soften the hardships and sweeten the lives of honest well-behaved working people.

My sympathies have ever been with working people. Bee-keeping has been commended to their attention, and my efforts to help them have been well appreciated, and far more influential than I expected at one time. The letters of thanks that I receive amply reward me for past efforts, and encourage me to go on and work while it is day. The profits of bee-keeping are relative. An income of £10, £20, or £40 a-year in addition to that of wages is a great consideration to a working man; whereas it is but "dust of the balance" to gentlemen of position and ample means. Forty shillings profit per hive annually is, in my opinion, an average and satisfactory return from bees well managed. The old-fashioned bee-keepers who have gone before us, and others who are coming after us, have been satisfied with an average return of £2 per hive yearly. If a working man has time and convenience to manage ten hives of bees and commence bee-keeping in earnest, he will find in time that the figures now given will represent approximately the average of his returns, if the price of honey continue at the present rate. We know that hundreds and thousands of working people in the country have both time and convenience for bee-keeping if they had the will and inclination. Any bit of a garden in a country town, or outside the town, will answer for an apiary. Any corner of a plantation, or wood, or a nest of whins, protected from boys and cattle, will do for bees. I am thankful to pay for the privilege of nestling a few hives underneath a hedge, or sticking them in a thicket anywhere in the neighbourhood of good pasture. I have not found an unfavourable position for bees, and care nothing for shade or sunshine—east, west, north, or south.

To those who intend to commence bee-keeping let me first say, Buy your hives as near home as possible. If you begin with stocks or hives at work they should come from a distance of about two miles. But swarms could be moved with safety on the day of swarming from any place near. If you cannot procure bees in modern hives, buy old-fashioned small English hives and begin with them. Make or buy larger hives for the swarms you obtain from these, for large profits cannot be had from small hives. Secondly, Increase the number of your hives by swarming till you possess the number you intend to keep and manage. Suppose four hives are bought in autumn and doubled in number by swarming next year, and suppose further that by taking the honey from the first swarms £5 or £6 profits could be realised during the first season, what should be done? If the profits are absolutely necessary in the first year reduce the number of stocks; but if not it will be better to keep all the stocks, and thus put yourself in possession of the means of gaining £15 or £16 a-year.

While the stocks are being increased in number the owner gains experience and lays his plans for future action. If a good and successful beginning be made, a bright and successful future lies before him, if weather permit. If he follows the swarming system of management his eight hives will be multiplied into sixteen or twenty. By taking the honey in autumn from eight or twelve of the best he will pocket a handsome return as his first-fruits of bee-keeping, and have larger and better stocks for the year following.

In good seasons we have two harvests of honey, as most of the readers of this Journal know. The first one comes from the stocks three weeks after swarms, and the later one from the first swarms at the end of the season.

On the non-swarming principle both super-comb and run honey may be obtained, but no increase of stocks of course. A hive that gathers 40 lbs. or 50 lbs. of honey into supers generally gathers a great deal in the hive beneath. After removing the super or supers I drive all the bees from a non-swarm, take its honey and feed the bees into a stock hive.

Some bee-keepers follow both systems of management, and some swarm all their hives with a view to fill supers. They put their first swarms into small (16-inch) hives, and super them soon after. This is a very commendable and profitable system.

Both systems, swarming and non-swarming, admit of various modifications. Happy and fortunate are those who begin well and receive encouragement and confidence at every stage of their course.—A. PETTIGREW.

OUR LETTER BOX.

MAGGOTS IN CHICKENS' CROPS (J. Douglas).—Pour a few drops of spirits of turpentine down their throats. A few drops will do, letting one drop at a time trickle down, and the spirit arising therefrom kills the maggots. Perhaps a little meal saturated with the spirits, given in the form of a pill occasionally, might have the desired effect.

FOUL BROOD (Ryecroft).—There is no cure for foul brood in hives; no

known method of preventing it from spreading when once there. We advise you to drive the bees from all your diseased hives into empty hives and feed them into stocks. When the bees are driven into empty hives they will form very small swarms, which at this late season should be united in pairs or placed in small hives. The hives containing the foul brood should be emptied, well scraped and cleaned, and thus prepared for use again. We have used hives that were diseased again and again, but never found that the hives themselves contained or carried infection.

DRIVING BEES—FEEDING (Novice).—You may easily drive the bees out of your small hive into a larger one. When the small hive is turned upside down tie a large towel or cloth round the rim, so that the larger hive may rest on it while the bees are being driven up. Drum pretty hard and constantly for twenty minutes. After the bees have fairly settled begin feeding them. One pound of sugar boiled in a pint of water should be given every night for four days, then double the quantity every night for eight days, thus giving the bees 20 lbs. of sugar in all in about twelve days. Keep the hive warmly covered, and contract the door to promote comb-building. It does not matter much whether the syrup is given at the top or bottom of the hive.

CHLOROFORM FOR TAKING HONEY (A. B. C.).—In taking bees from combs chloroform may be used in various ways. A piece of rag about 6 inches square may be saturated with a teaspoonful of chloroform, placed on a plate, and covered with perforated zinc. Raise the hive and place the plate with its contents on the board, and then close the door for fifteen minutes or less. The bees fall down on the board helpless and prostrate. The hive should be removed and the bees exposed to the atmosphere. The shorter the time the bees are under the effects of the chloroform the better is the chance of safe recovery. Though we have used chloroform successfully and without apparent injury to the bees, we do not recommend its use. If your heavy hives have young combs part of their contents may be removed, but if the combs are two years old the bees should be driven into empty hives and fed. Sugar-made stocks cost little and generally do well.

SUPERS NOT FILLED (J. Thatcher).—You have been very fortunate in having a super nearly filled on your first swarm this very unfavourable season. Your two stocks and the later swarm having had room enough below never needed the supers. If the season had been a honey one your bees would have filled all the supers. The casting-out of brood in unfavourable seasons is a common occurrence. It is an indication that the bees are either greatly discouraged by weather or fear the approach of famine. The brood of drones, useless members of the community at the close of seasons, is first sacrificed by a marvellously wise and instinctive economy. The heap of young drones now lying beneath the flight board is there because the bees want all the food of the hive for themselves. On examination you will perhaps find that they have hardly enough for the winter months. As the season for honey-gathering is over we advise you to remove the super that is nearly full, otherwise the bees may carry its contents below.

REMARKS.

8th.—Very bright early forenoon; cloudy showery afternoon, and very wet night.

9th.—Dull morning and very showery day, rather better towards the after part of the day.

10th.—Very fine morning; a very beautiful day throughout, except for a very short time about half past six, when it was very dark and stormlike.

11th.—A fair and pleasant day, rather rainlike about 2 P.M., and cloudy though fair during the remainder of the day.

12th.—Fine morning and pleasant day, though occasionally close and cloudy.

13th.—Gray morning, at times cloudy and stormlike, at other times very fine and bright.

14th.—A splendid summer day, bright, warm, and almost cloudless.

A week of moderately equable temperature, and although the mean is slightly in excess of last week, the heat has not been oppressive.—G. J. SIMONS.

COVENT GARDEN MARKET.—AUGUST 15.

BUSINESS remains quiet. We have no alteration to make in the price of vegetables.

From observation taken near London during forty-three years, the average day temperature of the week is 72.4°; and its night temperature 48.8°.

THE CULFORD GRAPE-VINE SPORT.

POSSIBLY it may be in the recollection of some of the readers of the *Journal of Horticulture* that this very unlooked-for production was described in its pages, as well as in that of some of its contemporaries, during the latter part of the year 1874, and frequently alluded to at periods subsequent to that date; and it may also be recollected that one or two writers upon the subject, who had not seen the sport in question, appeared to doubt very much the correctness of the opinions formed regarding it by those who had seen it.

At the time when these doubts were expressed in the gardening periodicals the sport or bunch of Grapes in question was not of course in existence; and the matter so far as it concerns the general public, or at least the portion of it who felt any interest in the subject, necessarily remained in doubt, as during the two succeeding seasons, although shoots were produced by the spur which had produced the remarkable bunch of 1874, these shoots showed no fruit during 1875 and 1876. During the present season, however, a bunch is again produced on the same spur, so that anyone who may feel interested in the matter may now examine it.

As many of your readers, it may well be supposed, have not seen the correspondence which took place upon the subject, or who may have forgotten all about it, I will recapitulate in as few words as possible the circumstances connected with the case, which are as follows:—Some twenty-five years since a house here was planted with what was at that time considered one of the best late varieties of Grape Vines—viz., West's St. Peter's, and some five or six years afterwards one of the Vines was cut down and grafted with the Black Alicante variety. A few years afterwards three distinct shoots of the Black Alicante had inarched upon them three very distinct and comparatively new varieties—namely, the Trebbiano, the Golden Champion, and Mrs. Pince's Black Muscat, each variety forming a distinct rod, which during several years continued to produce their respective kinds of fruit not apparently in any degree influenced by the stock, or rather the compound stock, upon which they grew. In January, 1874, the Golden Champion rod was cut out altogether, the severance taking place at a few inches below its junction with the Alicante stock; and during that season the two remaining rods—viz., Trebbiano and Mrs. Pince, bore their respective kinds of fruit as usual, with the singular exception of the Trebbiano rod, which on one spur near the centre of the rod produced a bunch entirely different from all the other bunches upon the rod, above as well as below this remarkable sport or deviation from the normal type of the Trebbiano variety; the appearance of this bunch being in all respects identical with that of the Golden Champion fruit, samples of which were close at hand and frequently compared with it.

Upon this circumstance being made public Mr. William Thomson of the Tweed Vineyard, Clovenfords, who was

the raiser of the Golden Champion variety, expressed his decided disbelief of the circumstance as related, and assured all who had seen it (he had not seen it himself) that they were deceived by the appearance of a bunch of the Trebbiano variety with unusually well-developed berries, &c. By this time the buds which were upon the shoot which had produced this bunch had been inserted as eyes, and I promised to send a plant to Mr. Thomson as soon as they became established in order that he might fruit it, but from some cause the buds all died. But at the end of the following season I sent him eyes from a shoot which had been produced from the same spur, but which had shown no fruit; and I think Mr. Thomson has stated that he had succeeded in striking them, and it is possible that some of them may now be in fruit, and if so, it will be interesting to know if they differ in any degree from the ordinary Trebbiano. No doubt Mr. Thomson will kindly furnish this information.

With regard to the bunch of fruit produced by the spur in question during the present season it is now (August 15th) approaching to a ripe condition, and this is very far from being the case as regards the other bunches borne upon the same rod; while the berries of the former are at least twice as large as those of the latter.

It has of course been very naturally supposed by some that the circumstance of the Golden Champion variety having for some years grown upon the same stock may in some way have influenced the Trebbiano rod as to induce this production; and this may or may not be the case. Sports or *lusus nature* occasionally occur in the vegetable as well as the animal kingdom, when it is, I believe, quite impossible to point to a cause for their development; and if the existence of the Golden Champion variety upon the same stock as the Trebbiano be supposed to have produced this effect upon the latter it seems strange that it should not have been developed until the former was removed. While again, if there is any truth in Mr. Murray's theory of the non-descent of the sap, then the one rod could have no influence upon the other whatever, as it will be seen that it is only by the action of a descending current through the medium of the stock that this could have been effected.—P. GRIEVE.

DISAPPOINTED EXHIBITORS OF ROSES.

IN the great (and every year increasing) competition of the present time it stands to reason that many exhibitors at our Rose shows are left out in the cold. No prize card adorns their stands, and after all the trouble they have taken and the expense to which they have been put, not only in rearing their plants but in bringing their blooms to the show, the result is very trying, and they are what these notes are intended to treat of—disappointed exhibitors.

There are very few of the most successful Rose growers, whether professional or amateur, who have not been in this sad plight some time or other, and I cannot well imagine anything more disappointing than to show in all the classes at a great show and to be placed in none. But recognising this, let us see what course is open to those

who, as a general rule, score blanks at the shows. "Cease to show," perhaps someone will suggest; "if you are always being beaten it shows that you have no idea of growing and showing Roses, so you had better retire." By no means, I answer; never say die, never give in; provided that you have the will you will find the way. Love mocks at all obstacles, and will obtain its object in the end.

My advice is not to aim at too great things; be content with moderate results. And why? Because it is evident that a large proportion of the exhibitors of the queen of flowers must, in some way or other, be placed under great disadvantages. They are what I may call handicapped, it may be as to time, or soil, or distance from the shows, but handicapped they are. By time I allude to inconvenient trains. Hercules at Heavittree begins to cut his blooms at 7 P.M., at which time I am well on my way to London. At the National and London shows many exhibitors cut their blooms the same morning. Now it is evident that the latter have a great advantage over those who are obliged to cut twenty-four hours earlier.

Then as to soil: some of our most successful exhibitors have splendid Rose soils. Mr. Jowitt at Hereford has one of the finest, not in England alone but I should say in Europe; Mr. Baker also has a rich red marl, the very sight of which puts you in a good humour. The same may be said of many other exhibitors; while, on the other hand, a great number have, like myself, a most miserable light, flinty, hungry soil, which is for ever crying, Give, give, and gives nothing in return. It does not stand to reason, then, that we can show on equal terms with men who enjoy all the advantages that we lack. So that we should be content with a less prominent position and do our best to secure not first, but second, or even third prizes. I am quite content if I get second to Mr. Baker at any time, and at the National was overjoyed at getting even a fourth.

But if first must be won by hook or crook, and nothing but the blue ribbon will satisfy, then I would recommend any ambitious exhibitors who are suffering from certain drawbacks or disadvantages to confine their attention to one class in the schedule, and let them have that class in their mind's eye, not only when they stage, but all the season through, and even the winter before. Let them buy their Roses so as to suit the class. If they are wise they will leave forty-eight distinct varieties to giants like Messrs. Baker, Jowitt, and Hole; and even thirty-six I would recommend them to leave alone. Twenty-four singles, or when obliged twenty-four trebles, is the class to suit them. In the autumn let them decide on the Roses which they purchase, not from the catalogues but from experience. Let them only buy those Roses which they know do well in their soil, and let them buy these in large numbers. However tempting *Marquise de Mortemart* or *Madame Furtado*, or any other weak growers may look on paper, let them not be induced to buy them. A man who wishes to show twenty-four trebles well ought to have about fifty good plants of thirty sorts (not including Teas). These should be planted with the greatest care, and great attention should be paid to the requirements of the various Roses.

Light Roses, such as *Marguerite de St. Amand*, *Mlle. Eugénie Verdier*, *Baronne de Rothschild*, and the like, should be planted where they can have the most sun; but dark Roses, such as *Baron de Bonstetten*, *Pierre Notting*, *Prince Camille de Rohan*, and others, which are apt to burn and shrivel under a fierce sun, should be placed where there is partial shade.

Every conceivable attention should be paid to these plants throughout the season. They should be mulched soon after planting, for I do not approve of digging-in rank manure at the time of planting, as I once lost a whole season's purchase by so doing; but the manure should be placed on the ground, leaving the winter rains to wash its virtues into the soil. In the early spring the ground should be lightly forked over, but care must be taken lest the roots, which then are just beginning to grow, be disturbed. About the middle of February the plants should be pruned, and, excepting the very strong growers, I recommend exceedingly hard pruning. After pruning the second dressing of manure should be applied, and about the first or second week in May the guano should be brought into requisition, but it must be sown with the very greatest care, and be used with great caution. It would perhaps be wiser for anyone who doubts as to the quantity to avoid sowing it at all, but to reserve it for liquid manure. It is so very easy to overdo it, as I know to my cost. During May and June when the weather is dry liquid manure of some kind or other must be frequently applied, and remembering that one good soaking is better than two or three insufficient waterings.

If all this care is taken and the season is moderately favourable, the man who shows twenty-four singles or even trebles from such a patch of Roses as I have named will, to say the least, not be a disappointed exhibitor.

But, if after all our labour the competition is so great that we find ourselves again left out in the cold, let not that fact dishearten us, or, what is still more to be dreaded, sour our tempers. I do not think we often find at our shows men who cannot stand defeat, but we do sometimes at very rare intervals meet with them. I have heard of exhibitors, and leading ones too, being so annoyed at their defeat as to threaten removing their boxes. Others, too, seem to think a personal wrong has been done them, and determine never to show again, at that place at all events. But for the most part old exhibitors take the matter of defeat as calmly and as pleasantly as if they had won the first prize, and that is the only way if we are to have pleasant meetings and happy faces. We cannot, perhaps, help feeling disappointed, but we can hide our feelings, or at all events not let our faces proclaim them.—WYLD SAVAGE.

STRAWBERRIES.

WHICH are the best kinds of Strawberries? is the query of many a puzzled beginner just now, and the answer is but too often preceded by an inquiry about the soil, as if certain sorts would only answer in certain soils, the fact being that all kinds grow strongly and bear fruit abundantly in a rich loam, or in soil that is brought by cultivation as nearly as may be into a similar condition to it. If, therefore, your soil be of a very light and sandy nature do not despair of growing fine fruit, but stir it deeply, mixing a heavy dressing of rich manure with every part of it, striving gradually to give "body" to it by such dressings of heavier soils as may be forthcoming. If, on the contrary, it is a heavy clayey soil, drain it thoroughly, mix as much leaf soil and rough gritty matter with it as you can obtain, so as to enrich, lighten, sweeten, and disintegrate it, and you will have an excellent Strawberry soil. But if, having a heavy soil of a close adhesive nature, and therefore very retentive of moisture, you do nothing more to ameliorate its crude condition than to dig-in a dressing of manure, you certainly establish no stronger right to assert that the sorts of Strawberries which fail in your mismanaged soil are only suitable for light soils than does the man who cultivates such light soil in a similar slipshod fashion to say that his failure arises from the planting of sorts that require a heavy soil, and I shall be glad to learn if anyone can advance any reason beyond the fact of their own failures in support of assertions that are calculated to puzzle and also to mislead.

Turning now to the special object of this note—a comparison of the relative value of different sorts new and old. The points of excellence which have most weight in making a selection are in the fruit sweetness, aroma, size, and form; in the plant fertility, a robust free growth, and hardiness. The early kind in which these points are most strongly developed is *Vicomtesse Héricart de Thury*, otherwise known as *Léon de St. Saumer* and *Duchesse de Trevis*. This is a wonderfully robust and hardy variety, cropping most abundantly, always having plenty of well-ripened medium-sized fruit in its season, very good in flavour, and a sure kind for preserving. It is quite the best sort for a small garden possessing no special facilities for high-class culture, and I strongly recommend it to your amateur readers, very few of whom can afford space for experimental gardening. Next in earliness come *La Grosse Sucrée* and *Sir Joseph Paxton*, both of much excellence; and as a midseason variety I must claim a leading position for *Dr. Hogg*, which under good culture is certainly our best kind in point of full rich flavour and size of fruit, which is very large, flat, and wedge-shaped. It answers admirably in pots as a successional crop to the early forced kinds; but I can only advise its use for pot culture in a large establishment having plenty of spare space under glass. *Lucas* is another fine-flavoured kind, old, but not half so well known as it ought to be. I have this season been through a very extensive collection of Strawberries containing very many old standard kinds and all the latest novelties, and I have to record that *Lucas* bore away the palm from every one of them for sweetness—sweetness which was most pleasing to the palate and quite devoid of insipidity. *Frogmore Late Pine* still holds the first place among late kinds; its abundant fruit is wonderfully juicy, sweet, and yet having a brisk acidity most grateful to the palate. I can hardly suppose "*AMATEUR*" of *Cirencester* has the true variety, as it is quite as late and infinitely superior to *Elton*.

I have selected these few old kinds from a large number of others, many of which are of much excellence, as I have no doubt that most gardeners will agree with me that it is far better to grow a few sterling varieties well than to waste space upon a lot of second-rate sorts merely for the sake of saying one has them. Among new kinds I can speak very highly of Laxton's Traveller. The long, tapering, handsome, and highly coloured fruit is most delicious in flavour, and so firm in texture as to well merit its name. Laxton's Exquisite, too, must become a general favourite; the fruit is globular in outline, very bright in colour, and of most delicious flavour. To these two must be added The Countess, termed by the grower the Strawberry of Strawberries. It has handsome fruit, in colour a very dark crimson, which is all the more striking from a very brilliant gloss upon its surface. So full of promise is the ripe fruit that one is apt to regard its fine flavour quite as a matter of course. I am very much mistaken if this trio of excellent novelties does not become very popular. I tasted a good many other new or but little known kinds, among others *Maréchal MacMahon*, *Helène Gloede*, *Auguste Nicaise*, and *Marie Nicaise*, but none of them impressed me as being worthy of a place in a selection of really choice kinds.

For those who care for large sensational fruit I may name *La Marguerite*, *Duc de Malakoff*, *Helène Gloede*, and *Cockscomb*, but it must not be forgotten that here we have size at the expense of flavour. If a white sort is wanted we have none better than *Bieton Pine*, an old but very good one.—
EDWARD LUCKHURST.

TROPÆOLUM JARRATTI CULTURE.

THIS is stronger in growth and has larger flowers than *T. tricolorum*, the flowers of both being scarlet, yellow, and black. Both are very neat twining plants, charming for covering trellises, which may be flat (in which form they form admirable floral screens) or globes; the leafless top of a Larch or Spruce tree when well covered has a fine effect.

The tubers require to be potted so soon as they begin growing, which is usually in August. They should have pots proportionate to the size of the bulbs. Large bulbs require 8 or 9-inch pots, whilst a 7-inch pot will accommodate a medium-sized bulb. I employ 9-inch pots, and have three bulbs in a pot, having a Spruce top for training the shoots to. The bulbs are placed triangularly in the pot, leaving a clear space in the centre for the introduction of the stem of the Spruce, which clear of the pot will be 2½ to 3 feet high, and half the height in diameter at the base, running up to a point so as to form a pyramid. I prefer this form because the plants take up less room.

Drainage is given to the extent of one-fourth the depth of the pot, covering it about an inch deep with the rough of the compost, which consists of equal parts of light turfy loam, leaf soil, and sandy peat, and a sixth part of silver sand. Fill the pots to within 2 inches of the rim, place the bulbs with the growing side upwards upon a little silver sand, and surround with the same material. Cover about an inch deep, the potting being done moderately firm. It is well for the soil to be in a moist state, but not wet, when employed for potting, so that necessity for watering may not arise until growth takes place.

The plants may be placed in any light airy cool house, and as soon as the shoots are long enough training should commence. The object should be to cover the trellis of whatever form it may be equally in every part with flowering shoots. Upon this depends in a great measure the beauty of the specimen, to secure which very frequent regulation of the shoots is required, not leaving them until they become entangled, it being difficult to disentangle them without much injury resulting.

Water should be given rather sparingly at first, avoiding at all times making the soil sodden, and yet the plants must not be allowed to suffer by want of water. If water be given when the soil is dry—a thorough supply—all will be well, making it liberal when the plants are in full leafage and advancing for flowering. When the flowering is past the leaves will shortly after turn yellow, when water should be gradually withheld, discontinuing it when they are all in that state. The bulbs after the stems are withered should be taken up and kept in a cool dry place until potting time again arrives.

They succeed admirably in a winter temperature from fire heat of 40° to 45°. Aphids sometimes attack them. It is best destroyed by fumigation with tobacco, but it is necessary that the foliage of the plants be dry and an overdose be not

given, or the foliage is liable to suffer. If your correspondent "Y. S. M." follows out this practice he will succeed in growing this attractive twiner.—A.

CUTTING DOWN VINES.

FROM time to time I have heard much about cutting down old trees to renovate them, and occasionally I have seen some wonderful effects from it in the orchard, &c., and it may be interesting to some of your many readers to record a case that occurred to a neighbour of mine, a market gardener, of success in cutting down Vines. Mealy bug unfortunately was introduced into his vineries and caused him much labour and anxiety, for he could not subdue the determined foe, and his Grapes were in a great measure unsaleable. These Vines were dressed by a powerful solution, which not only killed the bug but prevented the Vines breaking freely, and the rods were consequently cut down to the bottom of the rafters. New shoots were soon produced, and two canes were trained up from each old stem. These canes grew with great rapidity and soon reached the top of the house—beautiful clean rods, with foliage like leather that would have delighted any Grape-grower, very unlike the puny-leaved rods which were cut down. In the year following (1876) 60 lbs. weight of Grapes were cut from each Vine, or 30 lbs. off each of the young rods. I did not at all approve of such heavy cropping thinking it must injure the Vines, but on seeing them a few days ago I found them bearing I believe even a heavier crop.

I do not suppose that all old Vines treated so would show similar results; but where the soil is suitable, bunches turning small and Vines showing signs of being worn out, it might be worthy of consideration whether to make new borders and replant with young Vines or to try the cutting-down system. No doubt in the present case the odds were very much in favour of the cutting-down system, and the owner could not have hoped under the most favourable circumstances to have cut any such quantity from young Vines, and that without entailing the heavy expense of making new borders.

Another useful lesson may also be learned from the above occurrence—namely, the danger of applying strong remedies for destroying insects on a large scale before first having tested them on a single branch. I remember having read a few years ago of the virtues of paraffin oil as an insect-destroyer, and thought I would try it on a Green Gage Plum that was badly infested with scale, when it killed the scale by killing the tree.

I am well aware that the cutting-down of old Vines is not a new idea, as I have seen it practised many years ago, and have also seen the plan recommended in your Journal, yet the case mentioned was such a marked success that I could not resist the temptation of putting it on record.—J. B. S.

TRANSPLANTING TREES.

FOR some years I have adopted the plan I am to relate with great success. Where there are large plantations to make it is almost impossible to transplant all the trees in the months of October and November (the only really good months for transplanting) unless some different plan be used to that commonly adopted. I became so tired of seeing men spending two or three hours in digging up a tree—cutting off a large number of small roots or fibres, on which the tree depended for its growth—that I set to work to find out some quicker method. I commenced by making some very strong three-pronged forks, so strong as to admit of their being driven into the ground with heavy wooden mallets. I used them thus: Supposing you wish to operate on a Fir tree, say from 7 to 8 feet in height, a fork is driven in on each side of the tree; it is then moved backwards and forwards slightly and withdrawn. These forks are then driven in again between the two last cuts, and the tree is hoisted in the air, earth and fibrous roots coming up together. Supposing the tree has long straggling roots, it is necessary to cut them off at 4 or 5 feet from the stem. It is easy to see the direction in which the roots run during the time the tree is being suspended. To cut these roots I had a saw made by Burgess & Key, consisting of a stout stem 3 feet in length with a sickle-shaped saw at the end. This is thrust into ground, and the root is then cut off. When the tree is free and suspended a strong square plate of iron with rings at each corner is dragged under it, the tree is tied to each ring, and horses draw it to its destination. I moved eighty Fir trees last season. Every one has grown considerably. If there are no straggling roots the time occupied

for moving each tree is exactly two minutes. I will return to this subject.—OBSERVER.

SPIRÆA FILIPENDULA PLENA AND OTHERS.

YOUR notice of *S. arifolia* (page 94) prompts my referring to the very beautiful *S. Filipendula plena*. Foliage dense and Fern-like, forming an elegant clump with branching heads of snow-white flowers, double, therefore very enduring; flowering in July and August onward; very pleasing alike in borders, and for affording sprays (not scented) for bouquets and vases—a combination of qualities rendering it one of the best of hardy flowers. It attains to a height of $1\frac{1}{2}$ to 2 feet, though I have seen plants over a yard across and as much in height. Masses of it stand out grandly in the front of shrubs. Its roots are tuberous or knotted, propagation being effected by division in spring. Every crown with a portion of root will grow.

Although *Spiræas* in nature appear to prefer a moist situation, yet such is not by any means absolutely necessary, it being of far more consequence that they have a soil containing vegetable matter in a state of decay, or, failing that, liberal applications to the soil of leaf soil or manure. All they want is an abundance of humus. If the soil be dry we have only to water copiously and top-dress with rich vegetable refuse liberally. The best manure that I have employed is dried cow dung; it does not induce rank growth like the more stimulating horse and fowls' dungs.

There is no questioning the beauty of these plants in borders, nor their great usefulness for affording flowers for cutting, to say nothing of their remarkable adaptability for forcing; yet there is another purpose they might be put to with marked advantage—specimens dotted irregularly on grass, or a mass with irregularly disposed isolated specimens, there being a great want of colour in most pleasure grounds, and in many instances of form, which these and similar graceful or elegant plants or grasses would to a great extent supply. *S. ulmifolia* is a stately plant, *S. venusta* lovely, and *S. palmata* is very valuable.

All the *Spiræas* named, along with our very fine but neglected *S. Ulmaria*, and its red variety (*S. Ulmaria rubra*) and the variegated Meadow-sweet (*S. Ulmaria variegata*), are all available for forcing; but the most easily forced is *S. japonica*, though the others force readily enough if strong well-developed crowns are employed. But all have a decided dislike to tobacco smoke, the foliage being always more or less damaged by it whenever the house in which they are grown is fumigated; hence during fumigation I always have the *Spiræas* removed. *S. japonica* (*Astilba barbata*) with *S. palmata* are not with me hardy, the foliage being nipped by frost if after-growth has commenced in the spring; but the plants soon recover and make fresh foliage quickly, and flower later than usual. I have plants on a north border now (early August) well flowered.—G. ABBEY.

ROSE ELECTION.

OUR friend Mr. Hinton's decision to have an exhibition Rose election this year I think a very good one. In common with many of my professional brethren I wish, if not too late this season, it could have been extended to seventy-two exhibition varieties, the number required for a first-class stand, instead of forty-eight.

My reasons for wishing or suggesting it are that the exhibition class cannot at all be fairly represented by forty-eight varieties, when every amateur who exhibits in the class for forty-eight must grow at least seventy-two of the best exhibition flowers to meet the vicissitudes of our seasons. If a cold showery rosetide sets in, very many of our grand double Roses contained in the first forty-eight list will stain and not come out so well as thinner and often second-rate varieties, so that amateurs should grow nearly double the number of kinds they intend to exhibit to be ready for any season.

I am aware it may be said the collective number of varieties sent in by numerous rosarians as last year would swell the list to more than seventy-two to select from; but this, I think, will not meet the case, as in some of the previous Rose elections many of the old yet good second-rate Roses very well known were repeated over so many times that an undue prominence was given to them over better Roses less seen and known. I would ask Mr. Hinton if it would not be best to more distinctly divide this forthcoming exhibition election into two classes—northern and southern exhibitors; and if some, say twelve able

southern professionals, as well as an equal number of "ex-professional" amateurs, would kindly send in their lists of the best seventy-two exhibition Roses, arranged, as Mr. Hinton suggests, in order of merit, we should then have a truly valuable official guide for all exhibitors throughout the southern half of England. The same thing would of course be done for the northern half—Scotland and Ireland.

I will conclude these remarks by giving the names of the southern professionals who I earnestly hope will this season give our able returning officer their lists and support, as it will greatly help the exhibition cause—making more rosarians, enabling them to spend their energy and strength only on the best varieties to the exclusion and weeding from our too lengthy catalogues of worthless varieties which have not been proved on the exhibition table. A word another time about the best garden Roses—the stay-at-homes; they must and will be sharers in the spoil. Here follow names and invitation to Messrs. Cant, Cooling, Corp, Cranston, Davison, Durbin, Keynes, Mitchell, Paul, Prince, Turner, Walters, Curtis.—H. C. Torquay.

THE CIDER FRUITS OF HEREFORDSHIRE.

THE FOX-WHELP APPLE.

(Continued from page 132.)

FIG. 28 at page 132 is taken from a good specimen of the fruit which was exhibited at the meeting of the Woolhope Club at Hereford in 1876. The fruit came from a tree which had been in possession of the same family for 130 years, and the tree itself is supposed to be 200 years old. FIG. 29 (page 132) represents a longitudinal section of the fruit exhibiting the structure of the eye, the tube, and the core; and the lower part is a transverse section of the same fruit showing the formation of the cells.

Fig. 33.

The form of the fruit varies according to the age of the tree, and this is the case with most varieties. FIGS. 33 and 34 are taken from fruit grown by John Bosey, Esq., of Lyde, and exhibit the result of successive graftings from one graft taken originally from one of the old trees of the Fox-whelp. FIG. 33 represents a fruit from a tree which is the result of four successive graftings, the scions being taken in each instance from the tree grafted the previous year; and fig. 34 is that from a tree which has had the grafting repeated five times.

The home of the Fox-whelp Apple, be its origin what it may, is in the deep clay loam of the old red sandstone in the central districts of Herefordshire, and especially in the valleys of the rivers Lug and Froome. The chief orchards in the villages of Lugwardine, Westhild, Withington, Holmer, Lyde, Moreton, Sutton, Wistaston, Marden, Bodenham, Burrup, Wellington-on-the-Lug, and those of Weston Begard, Yorkhill, Stretton, Granditon, Eggleton, the Froomes, the Cowarnes, and other villages on the Froome, are seldom without several old trees of the Fox-whelp Apple. The broad valley of the Wye does not generally present so good and rich a soil. The river has been so erratic in days gone by that large beds of gravel and marl are to be met with in all directions, and the orchards of repute therefore are only to be found on the rising slopes of the valley out of the river's reach. Here are many excellent

orchards from King's Cople and Holme Lacey by Credenhill to Kirmersby, Samesfield, and the Weobley district. The Fox-whelp may be found in any of them, and wherever it is found it is treasured greatly for its own cider, unmixed where the trees are sufficiently numerous to make it, or for giving strength and flavour to the mixed cider where they are in fewer numbers.

The Fox-whelp Apple tree is upright and handsome in growth where age has not rendered it rugged and gnarled. In some situations its growth is peculiar; it bends at an angle as the branches are given off, and these elbows will here distinguish the Fox-whelp tree from those of other kinds; but this is not general. The tree is hardy and productive, and its fruit in great demand. There is yet a want of young trees generally,

Fig. 34.

for, be the reason what it may, grafts of late years have not succeeded well.

The Fox-whelp cider when pure is of great strength, and always has a peculiar aroma, so marked that it can be detected directly the cork is drawn from the bottle. In taste it is generally rough and strong, with the peculiar musky flavour that gives its aroma. In ordinary seasons, unless made with great care, it is not sweet enough to be acceptable to strangers, and the taste which enjoys its peculiar flavour fully must in such circumstances, perhaps, be acquired; but in a favourable year—a year of sunshine and genial showers, when the fruit has been ripened to perfection—happy is he who has a good hit of it. If he carries it well through the process of fermentation and keeps the flavour of the fruit and its sweetness too he has cider in perfection—a cider that will sell readily in its own district at a guinea a dozen. It will not all be sold, however, for it is the pleasure and pride of the cider-growers of Herefordshire to have always ready for a friend a bottle of good Fox-whelp cider of a good year. The Fox-whelp Apple is, however, most used to give strength and flavour to the cider of mixed fruit, and when this is well made it is perhaps more generally popular than the very strong and pure Fox-whelp. A cider of this kind, excellent in quality, can be got at 1s. a bottle from the growers. The Fox-whelp cider has the character of changing colour very quickly on exposure to the air, and even at the table if not drunk quickly the dusky greenish tint will show itself. Some other strong ciders have also this peculiarity, which is certainly not a virtue.

The Fox-whelp Apple sells well in September as a “pot fruit.” Its brilliant colour recommends it to everyone, and its piquant rough flavour is pleasant to all who have learnt to appreciate its cider. It is an excellent cooking Apple for pies and puddings, and “the Apple of all others to make sauce for the Michaelmas goose or a roast leg of pork.”

A Fox-whelp Apple of good size and colour yielded $7\frac{1}{2}$ drachms of a strongly acidulated juice with its own flavour, and of the specific gravity of 1068; and others of smaller size gave

$5\frac{1}{2}$ drachms of juice with a specific gravity of 1074. Mr. Knight gives the higher specific gravity of 1076 to 1080, which perhaps might be due to a more favourable year.

Different Apples have been in favour with cider makers at different periods. The Gennet Moyle had to give way to the Red Streak, and both have had to yield the palm to the virtues of the Fox-whelp. Beyond all question this is now the favourite Apple.

There are several varieties of Fox-whelp, called “Bastard Fox-whelp” in common language. A “Black Fox-whelp” is also thought much of in some orchards, and is said to be the same Apple that is so highly esteemed in Somersetshire.

TAUNTON DEANE HORTICULTURAL SOCIETY.

THE handsome and cleanly county town of Somerset once more put on its holiday attire on the occasion of the tenth annual Show of this Society, and entered, as is the wont of these western towns, *con amore* into the engagements of the day. To all classes it seemed a general holiday, the county gentry attending in large numbers, while the market people and labouring classes seemed to enter into it with as much interest as their leaders. The Vivary Park, in which the Show was held, was thronged with visitors, contrasting most favourably with the cold and hesitating manner in which such events are regarded in the east of England. The Exhibition itself was a remarkably good one, and both amateurs and nurserymen contributed in great force to its success. There were five tents, one devoted to the productions of nurserymen—plants and flowers, a similar one to those of amateurs, another to fruits and vegetables, a fourth to cottagers’ productions, and a small one for the contributions of ladies in table decorations and bouquets. Of the whole Show it may well be said that the exhibits were remarkably good. It often happens at provincial shows that a good deal of rubbish is allowed to be put up, but with only one or two exceptions nothing unworthy of the exhibitors was shown. One or two features marked this as distinct from its predecessors of the last few years—the disappearance of Mr. Cypher, who has disposed of his large plants, and the re-appearance as an exhibitor of that hearty and enthusiastic patron of horticulture, Mr. Marshall of Taunton, whose charming residence of Belmont I once attempted to describe in the Journal.

In the classes for large plants, stove and greenhouse and exotic Ferns, the chief prizes fell to Messrs. Lucombe, Pince, and Co., whose plants were marvels of good cultivation; and it is clear from what I saw here that it is only the great distance, trouble, and expense that prevents this well-known firm from successfully competing at the metropolitan shows. Their Ferns were truly grand, and the splendid examples of Allamandas, Ixoras, Clerodendrons, &c., were worthy of all the admiration they received. In the cut flowers there were some splendid exhibits. Messrs. Kelway & Son exhibited, not for competition, a grand collection of their seedling Gladioli (three dozen), amongst which were some quite new flowers of great excellence, to which no fewer than six first-class certificates were awarded. They occupied one extremity of the staging, and were surrounded by groups of admiring visitors throughout the day. In Roses Mr. Corp of Oxford was the chief exhibitor. I have seen a few Roses in my day and think I know something about them, but I can safely say that I never saw in the month of August such stands of blooms, and in this opinion I was not singular. Devienne Lamy, Charles Lefebvre, Marguerite Brassac, La France, and others were simply magnificent, especially the first-named; they were all grown on the seedling Briar, and afforded another proof of the value of that stock. In Dahlias Mr. Keynes was first with blooms displaying the well-known finish and excellence that always has characterised the Salisbury blooms. Mr. S. Dobree, an amateur, was an excellent second. As the class was an open one his Verbenas also were very fine.

In the amateurs’ tent the chief prizes for plants were awarded to Mr. Lawless of Exeter and to Mr. Marshall. These plants, although not so large as the nurserymen’s, were very good, and the Ferns especially so. Mr. Marshall also took first prizes for Gladioli and for some splendid examples of Achimenes such as we are not in the habit of seeing about London. The chief prizes in florists’ flowers fell to Mr. Dobree, whose Dahlias, Verbenas, Asters, &c., were very fine.

The fruit, as might have been expected, was not remarkable, but the vegetables were very fine; and the cottagers’ productions were both numerous and very excellent in quality, while they displayed a good deal of taste in their arrangement of flowers.

The weak point of the Show was the table decorations. Fair prizes were offered, and yet but two exhibitors competed, and of these the less said the better. As I have once before said this is a wonder, for they have had benefit of the very best examples, as Miss Hassard once exhibited here, and yet nothing could be poorer than the two tables arranged on this occasion.

Need I add that the arrangements were excellent, that the

Secretary and Committee worked heartily, and that kind feeling and good fellowship marked all the proceedings of the day, which I hope may also have proved financially a success.—*D., Deal.*

STRAWBERRY CULTURE.

I AGREE with "W. S. P." that there is a great difference in the proper treatment of Strawberries on light and strong soils. My soil is a sandy loam, and runners, however carefully prepared, will not give a good or full crop of Strawberries the next season, but the second—that is, two years after planting, they are fine, and if proper care is taken in cutting-off the runners and separating the plants immediately after the fruiting season is over, not delaying the work till the rows are matted into one whole bed, there will be just as good if not a better crop, with a winter's mulching of manure, the third year as the second. Strawberries in light soil by careful management may be made to bear good crops for many years. No doubt in strong soils the plants may be fruited one year after planting and produce good crops, but Strawberry runners in strong soils are seldom fit for early planting.

It is a good plan, if the ground is not ready to plant early in August, to prick runners in rich soil under a cold frame. I have frames for this purpose about 9 feet long and 2 feet wide, the glass being merely loose strong sheets of 21-oz. glass 2 feet long and 20 inches wide laid on the top of the frame and secured with a wire pin. The frames are made slightly to slope, being about 7 inches high at the back and 3½ in the front, and grooved at the back to hold the glass. The corners of the frames are raised on bricks. As the Strawberry runners grow care is taken to keep them well watered, and to prevent fresh runners being thrown out. If planted about 5 or 6 inches apart they may be taken-up with balls and transplanted whenever the ground is ready, and they will do better than runners taken off the plants earlier and put into their fruiting quarters at once. As to distance, the rows should not be less than 2 feet apart nor less than 20 inches between the plants. Never make a bed of more than three rows, then leave a space of 4 feet so as to make your distance between the beds double that between the rows; this not only gives room for picking, but prevents the sorts running one into another and becoming mixed. In light soils mulch well in the winter months. Take the mulching off in the middle of April, leaving the beds exposed to the full sun and air till the flowering season, then litter the ground (after giving a good watering with liquid manure if the soil is at all dry), with chopped straw strewn not too heavily between and amongst the plants. It has one great advantage over long straw, that the plants do not require to be so much pulled about by the hand, and that no snails or slugs can work amongst it, especially if barley straw with barley chaff is used. Now as to sorts.

I have discarded Black Prince and Keens' Seedling. I find no sorts so good for general purposes as Vicomtesse Hericart de Thury, Sir Joseph Paxton, Lucas, and President; then for late, Myatt's Eleanor and Eliza. Dr. Hogg and British Queen do not do well with me. Amongst other very good sorts are James Veitch, a fine large Strawberry and free bearer; Cockscorn, Bonne Bouche, and John Powell. Among newer varieties Traveller promises exceedingly well; La Grosse Sucrée is a very handsome fruit, but not so good as it looks; Souvenir de Kieff is with me a decided failure, only slightly better than Sir C. Napier, which is soft and tasteless. Amongst other sorts I have tried and discarded are La Constante, Carolina Superba, Aromatic, Royalty, Sabreur, and Triomphe de Paris (the latter is very fine flavoured but delicate), Ne Plus Ultra and Comte de Zahn. Another Strawberry I have forgotten to mention is Princess Dagmar, very good in point of flavour, evidently with a cross of the old Hautbois in it; and Filbert Pine is worth trying in most gardens.

I was in hopes of being able to give some report of twelve seedlings kindly sent me by Dr. Roden, but the season has been so very bad for Strawberries here, especially in a new quarter recently added from a grass field, even though the top spit with the grass on it was carefully buried not far from the surface, that I cannot give a very definite report. Those which I was much pleased with were Early Filbert Pine, Scarlet Pine, Excelsior, Enchantress, Duke of Edinburgh, and Hundredfold; but the trial has not been a fair one, as after an open winter we had cold winds and bitter frosts in April and May till nearly the second week in June, then a period of dry weather for three or four weeks, followed by deluges of rain just as the fruit had set, and the quarter where these plants

were growing proved too light and sandy, and exposed too much to full sunshine. The sorts I had on trial were Sir John Falstaff, Bonny Lass, Gipsy Queen, Amy Robsart, Hundredfold, Alpha, Excelsior, Scarlet Pine, Early Prolific, Duke of Edinburgh, Early Crimson Pine, and Enchantress. They nearly all seemed to be a high quality of fruit and good bearers, but for the reasons before stated the trial has not been satisfactory.

To conclude, I do not on the whole know three better Strawberries for general purposes than Lucas, Sir Joseph Paxton, and President. I do not think Lucas is sufficiently known or grown. It is not a very large Strawberry, but possesses fine flavour, is very firm, and stands all weather well, is a sure setter, and lasts a long time in season.—C. P. P.

ROYAL HORTICULTURAL SOCIETY.

AUGUST 21st.

ONLY a little fruit was submitted to the Committee on this occasion, yet the Council-room presented an attractive appearance, for the tables surrounding the room were quite filled with plants and flowers, several of which well merited the marks of approval expressed by the Committee.

FRUIT COMMITTEE.—Henry Webb, Esq., V.P., in the chair. Mr. Burnett, The Gardens, Deepdene, sent a well-netted and good-flavoured fruit of Melon Incomparable, for which a letter of thanks was voted; a similar mark of recognition being passed to Mr. Long, gardener to J. S. Law, Esq., South Lodge, Reigate, for a very large and good seedling Melon named South Lodge. Mr. Tillery, The Gardens, Welbeck, sent a dish of very fine Victoria Nectarines, and was awarded a cultural commendation. Messrs. Kelway & Son, Langport, sent Cucumber Lord Beaconsfield, which was not considered sufficiently distinct from the old (not Rollinson's), Telegraph; also Prince of Wales, which closely resembles Daniell's Duke of Edinburgh. Mr. Morse, gardener to W. Procter Baker, Esq., Bromwell House, Burlington, Bristol, sent a seedling Grape the result of a cross between the Black Hamburg and Muscat of Alexandria: It is amber-coloured, but as exhibited was not considered to possess special merit. Louis Killick, Esq., Langley, Maidstone, sent a dish of "Stone" Apple, an early free-bearing kitchen variety which is very popular in Kent, but the fruit was not sufficiently ripe for adjudication. From the Society's Gardens came a dish of American Crab, very good; Madeleine Royal and Royal Muscadine Grapes, Trebons Onions, and a coarse-looking Cabbage named "Santung." In answer to an inquiry as to classing Rhubarb as a fruit or a vegetable, it was decided that it might be most properly exhibited as a vegetable only.

FLORAL COMMITTEE.—G. F. Wilson, Esq., F.R.S., in the chair. Messrs. James Veitch & Sons, Royal Exotic Nurseries, Chelsea, exhibited a collection of choice plants, including several Orchids. Cattleya gigas had gorgeous flowers, and Cattleyas Loddigesii and dolosa, Laelia Dayana, Dendrochilum filiforme, and others were very attractive. Lapageria alba, a small plant with handsome wax-like flowers, spoke for itself of its great value as a decorative plant. Abutilon Boule d'Or, a new free-flowering variety of great promise, was exhibited by this firm. The flowers are a soft yet bright yellow, and contrast effectively with the dark green foliage. Also a very distinct Begonia, Queen of Whites, of the B. Veitchii type, the flowers being almost pure white, large, and of great substance. A first-class certificate was awarded. A similar award was made for Oncidium protexum, very free, yellow lip margined with chestnut.

Mr. B. S. Williams, Victoria and Paradise Nurseries, staged a small collection of plants, including a splendid specimen of Ixora Williamsii, showing its floriferous character, the plant having flowered twice previously this year. It is one of the most distinct and valuable of the Ixoras. Mr. Williams also exhibited Croton fasciatus with very large Magnolia-like foliage, veined and margined with yellow; also Lilium auratum maculatum, densely spotted; and Phaius Dodgsoni. This is a fine Orchid, the growths of 2 to 3 feet high, terminating with short spikes of a dozen flowers, ivory white with pale cinnamon lips—very attractive. A first-class certificate was awarded to this plant, and a vote of thanks for the Ixora.

Messrs. Kelway & Son, The Nurseries, Langport, Somerset, exhibited spikes of fifty varieties of new Gladioluses, which produced a rich effect. A vote of thanks was awarded for the collection, and first-class certificates for the following five varieties:—Cymbaline, pink with faint stripes of rose, and white centre; the prevailing colour of the flowers being much like that of Odontoglossum vexillarium; very smooth and fine. Prince George, a rich flame scarlet with crimson base and faint white stripes; very effective. The Odalisque, creamy white, with claret throat—a smooth charming flower of great substance of petal. Charles Noble, orange scarlet, flaked and feathered with rose and white; striking. Baroness Burdett Coutts, white with a claret blotch, shaded with violet; extra

fine. Mr. Kelway also exhibited spikes of *Hyacinthus candicans*.

Mr. Long, gardener to J. S. Law, Esq., South Lodge, Highgate, exhibited several plants of *Tuberous Begonias* which had been potted from the open ground. They are seedlings raised by the exhibitor, and are dwarfier in habit and more floriferous in character than any we have hitherto seen, and are undoubtedly admirably adapted for flower-garden decoration. A vote of thanks was awarded.

Mr. J. Fraser, The Nurseries, Lea Bridge Road, London, exhibited two seedling *Ixoras*, to one of which—*I. formosa*, bright lemon-coloured, and very free—a first-class certificate was awarded. Mr. Perkins, Leamington, had a first-class certificate for *Begonia Empress of India*, rich crimson, vigorous, and fine. Mr. Perkins also exhibited some bright seedling *Phloxes*.

A "Blue Spruce"—*Colorado Menziesii*—was exhibited by Mr. Anthony Waterer of Knap Hill, Woking, and received a first-class certificate. It is free in growth, dense, and of fine glaucous tint; very distinct. Cones of several *Conifers* were also exhibited by Mr. Waterer, and flowering sprays of *Andromeda arborea*, for which a vote of thanks was awarded.

Mr. Cannell, The Nurseries, Swanley, Kent, exhibited cut blooms of double *Pelargonium Madame Thibaut*, one of the most valuable of the double varieties; also dwarf *Lobelia Brighton*, very dense and rich. A vote of thanks was awarded. Mr. Green, Holmesdale Road, Reigate, exhibited *Streptocarpus Greeni* and a rosy white variety named *Delicata*, very free and attractive, for which a first-class certificate was awarded. Mr. Green, gardener to Sir G. Macleay, Bart., Pendell Court, Bletchingly, had a second-class certificate for *Cœlogyne corrugata*. I. Anderson-Henry, Esq., Edinburgh, sent a species of *Primula* from Sikim. The plant is small, leaves much toothed, and flowers rich violet. A botanical commendation was awarded. Mr. R. Parker, Exotic Nursery, Tooting, submitted flowering sprays of *Rubus fruticosus flore-pleno*, very double, and received a vote of thanks.

From the Society's gardens, Chiswick, were exhibited *Abutilon Lemoinei*, the same as noticed in Messrs. Veitch's collection under the name of *Boule d'Or*, to which a first-class certificate was worthily awarded, a similar award being made for *Torenia Fournieri*, richer in colour than *T. asiatica*, and having in addition a golden blotch on the lip; a free-grower and bloomer, and an attractive plant. Also double *Pelargoniums*, to two of which, *Littre (Lemoinei)*, purplish crimson, and *Lafayette (Lemoinei)*, rosy salmon, first-class certificates were awarded; a splendid collection of *Dianthus chinensis*, *Hedderwigi*, and other varieties, and brilliant-coloured *Salpiglossis*.

A resolution was passed by the Committee recommending to the Council the importance of a speedy issue of the schedule of the provincial show to be held next year, in order that exhibitors may have ample time afforded them to prepare their plants.

THE MARQUIS OF BUTE'S HARDY VINEYARD.

For the last two or three years gardeners of all grades, and many others besides gardeners, have wondered how the undertaking of a hardy vineyard would succeed. It is only now that success is beginning to show itself. Previous to this the Vines have been establishing themselves; now they have passed into a fertile state. The vineyard is not at Cardiff Castle, but five miles from it at Castle Coch, which is an old British fortress, and stands upwards of 300 feet above sea level. Here the Vines are planted in an ordinary field with a common hedgerow round it. The soil is moderately light red loam not more than 2 feet deep, and rests on a rough naturally-drained bottom of limestone. The field has a very sharp slope to the south. A wooded hill shelters it completely from the north, and plantations screen it from east and west, but to the favourable south it is fully exposed; and standing amongst the Vines and looking in this direction the Severn and coast of Somerset and Devon a delightful prospect is looked upon.

Three thousand Vines were planted three years ago, other three thousand were planted or inserted as cuttings like Gooseberries this spring. All are planted in rows 3 feet apart. The oldest are supported by stakes 4 feet high. At this height the Vines are permanently stopped. Two and three shoots are taken up from each root. The sorts are principally *Gromier Noir*, black, and *Melior Blanc*, white. The first-named is the freest fruiter. All are bearing fruit, some of them having as many as seven bunches. Hardly any of the bunches are more than 1 foot from the ground. No kind of vegetation could possibly be in better health or more vigorous than the Vines. The wood is strong, very firm, and the leaves most luxuriant. Up to the present time the progress and state of the whole concern may be briefly summed up as follows:—Site the most favourable in the United Kingdom, Vines in the most satis-

factory condition, management so good and intelligent that if Mr. Pettigrew fails no other one need try on this side the English Channel.—M.

GLAMORGANSHIRE HORTICULTURAL SHOW.

THIS Show was held at Cardiff on the 15th inst. The arrangements were very complete. The whole exhibits were divided into six classes, and each class had a suitable tent to itself. Plants were generally good, cut flowers and vegetables abundant, but fruit scarce. Altogether, however, although only about £300 were offered in prize money, we have seen a much inferior display where more than double that amount was given. There was one great omission on the cards—the names of the employer and gardener were given, but where they came from there was no possibility of learning.

Fruit, as we have already said, was scarce, and this we know was alike regretted by gardeners and other visitors. There is nothing about an exhibition of this kind so attractive as plenty of fruit, and committees will find out in the long run that it is a great mistake to make fruit a minor consideration in their autumn schedules. For a collection of nine sorts of fruit only £3 was offered. Lord Tredegar was first, Colonel Page second, and Mr. W. Banes third. Each collection was composed chiefly of Grapes, Melons, Peaches, Plums, and other small fruits of average merit. For one Queen Pine Mr. Pettigrew, Cardiff Castle, was first with an excellent fruit, and although others were staged this was far in advance of them. Mr. C. P. Phillips was first for three bunches of white Grapes with Muscat of Alexandria. The three weighed 13 lbs., had well-swelled berries and good-shaped bunches, but not quite ripe. Mr. Pettigrew was second with well-finished bunches of *Poster's Seedling*. For three bunches of black Grapes Mr. Phillips was also first with *Black' Hamburg*. These were riper than the Muscates and weighed 16 lbs. Where Mr. Phillips came from we cannot say, but we heard that his place is new and his Vines only three years old, and if this is the case we may expect to hear of him again, as his bunches were much above the common size. Lady Clive, who had many prizes for other exhibits, was second in this class. For the best Melon of any kind Mr. Pettigrew was first with *Read's Hybrid*. The prizes for Peaches, Nectarines, Figs, Apples, Pears, Plums, &c., were mostly won by Lord Tredegar, Colonel Page, Mr. Barnes, and Lady Clive.

£15, £10, £5 were offered for twelve stove and greenhouse plants. This brought out four or five collections. The first prize was awarded to Mr. Pilgrim of Cheltenham; the second to Mr. Barnes; and the third to Messrs. Heath & Son, nurserymen, Cheltenham. *Dracænas*, *Crotons*, *Palms*, *Heaths*, *Dipladenias*, and plants of this description were in each of the collections.

For eighteen varieties of Roses, three blooms of each, Messrs. Davidson & Co., Hereford, were first; Messrs. Cranston & Co. of the same place second; and Mr. Treseder, Cardiff, third. Some of the blooms were very fair, but many of them too open. For twelve Teas Lord Tredegar was first, Messrs. Cranston and Co. second, and Messrs. Davidson & Co. third. These stands were much superior to the last named.

The special prizes offered by Mr. Hooper of Bath for twelve Carnation blooms, and the same number of Picotees, were won by Mr. Francis and Mr. Catley. Like all provincial shows at this season, there were immense quantities of *Phloxes*, *Pentstemons*, &c., shown. Vegetables were also shown in great abundance and of superior quality. The principal prizetakers in this class are named amongst the fruit exhibitors above named. Potatoes, although much affected with disease in South Wales, were shown in good condition.

Floral devices and decorated dinner tables were attractive. For the latter Miss Watson was first with a very elegant arrangement, Miss James second, and Miss Binns third. Where any deficiency occurred in the tents, especially the largest tent, groups of flowering plants from Cardiff Castle filled-up the blanks and added very much to the general effect.

NOTES AND GLEANINGS.

We are requested to announce that a GRAND SUMMER SHOW of the Royal Horticultural Society will be held in 1878, at South Kensington, extending over four days, from Tuesday, May 28th, to Friday evening, May 31st, inclusive. The schedule is already prepared, and may be obtained on application to the Secretary at South Kensington. We are also informed that no time will be lost in preparing a schedule of the great provincial Show to be held at Preston in June, 1878, and that the preliminary arrangements are already far advanced.

— On Saturday last an exhibition of a novel character was held in The Shrubbery, Upton, near Plaistow, Essex. The exhibitors being children connected with the South Essex Band

of Hope Union. There were 145 exhibitors, and twelve prizes were awarded; a large proportion of the plants were particularly well grown, especially the Fuchsias and Geraniums. The prizes, which were composed of useful and ornamental articles, were much appreciated by the boys and girls who were fortunate enough in winning them. The Show was very creditable indeed to the Committee, but another season it would be desirable to increase the number of prizes, as a number of well-grown plants were omitted out of the prize list altogether for want of funds. From the gardens of Mr. Alderman Finnis, Park Gate, Wanstead, came a collection of Orchids and fine-foliaged plants for exhibition, also a group from Forest House, Leyton, the residence of Mr. Fowler. And we also noted a collection of *Gladiolus* spikes sent from the gardens of F. Whitbourn, Esq., Ilford.

— MR. CUTLER, Secretary of the GARDENERS' BENEVOLENT INSTITUTION, will, we understand, attend the principal horticultural shows for the purpose of inducing gardeners to subscribe to the Institution.

— ALTHOUGH rain in the northern and some of the midland districts has been excessive, the neighbourhood of London affords unmistakeable signs of drought. The commons southward of the City, such as Clapham, where the soil is gravelly, are quite brown and have a much more baked appearance than they have previously had during the summer. The trees, such as Chestnuts and Limes, have a rusted appearance, and their leaves are commencing falling. Rain, which was needed in gardens, also fell heavily yesterday morning.

— We are informed that rain has been falling almost every day lately in the neighbourhood of Edinburgh, and that great fear is entertained that the POTATO DISEASE will be very destructive unless a sudden and favourable change should occur to check its progress. In the south the fine weather continues favourable for the grain and Potato harvests.

— OUR correspondent "B. G., Co. Down," writing on the POTATO DISEASE IN IRELAND, states that he has seen the murrain in many districts. The spring was very backward, and the seed was late planted. Much loss is anticipated amongst the late varieties, as they are now in full growth. The Skerry is almost blight proof, but cannot be cultivated except in fields or on maiden soil.

— MR. ROBERT OSBORN of the Fulham Nurseries informs us that he has purchased, as from the 1st January last, the nursery and seed business, carried on for many years at Fulham and Sunbury by his late uncle and father, William and Thomas Osborn, and his grandfather, Robert Osborn. This arrangement has received the sanction of the Judge of the Chancery Division of the High Court under whose direction and control the business was conducted for the last few years prior to the present proprietor buying the same. The style of the business will remain as before—"Osborn & Sons."

— AT the FLORAL CONCERT to be held at the Agricultural Hall on the 28th inst. prizes varying in amount from £50 to £2 are offered for flowers, fine-foliaged plants, fruits, fountains, and other subjects connected with gardening. It ought to be a largely attended assembly.

— THE *London Medical Times* states that the mines of Laurium are generally known to be largely encumbered with scoriae, proceeding from the working of the ancient Greeks, but still containing enough of sillon to repay extraction by the improved modern methods. Professor Hendrich relates that under these scoriae, for at least fifteen hundred years, has slept the seed of a POPPY of the genus *Glaucium*. After the refuse had been removed to the furnace from the whole space which they had covered, have sprung up and flowered the pretty yellow corollas of this flower, which was unknown to modern science, but described by Pliny and Dioscorides. This flower has disappeared for fifteen to twenty centuries, and its reproduction at this interval is a fact parallel to the fertility of the famous "mummy" Wheat.

— DR. GEORGE BIRDWOOD writes in the "Academy":—"The most sacred plant in the whole indigenous materia medica of India is the TULSI OR HOLY BASIL (*Ocimum sanctum*), sacred to Krishna, and called after the nymph Tulasi, beloved of Krishna, and turned by him into this graceful and most fragrant plant. She is, indeed, the Hindu Daphne. The plant is also sacred to Vishnu, whose followers wear necklaces and carry rosaries (used for counting the number of recitations of their deity's name), made of its stalks and roots. For its

double sanctity it is reared in every Hindu house, where it is daily watered and worshipped by all the members of the household. No doubt also it was on account of its virtues in disinfecting and vivifying malarious air that it first became inseparable from Hindu houses in India as the protecting spirit or Lar of the family. In the Deccan villages the fair Brahminess mother may be seen early every morning, after having first ground the corn for the day's bread and performed her simple toilet, walking with glad steps and waving hands round and round the pot of Holy Basil, planted on the four-horned altar built up before each house, invoking the blessings of Heaven on her husband and his children—praying, that is, for less carbonic acid and ever more and more oxygen. The scene always carries one back in mind to the life of ancient Greece, which so often is found to still live in India, and is a perfect study at once in religion, in science, and in art."

— We are informed that a considerable number of entries have been received for the great show to be held at Carlisle, and that preparations for the Exhibition are in an advanced state, the show-ground already being enclosed.

— THE *employés* of Messrs. James Carter & Co. were entertained by the firm to a dinner at Sydenham on Saturday last. Forty-four of them—twenty-two from the Holborn establishment and the same number from the Forest Hill Nursery—having previously engaged in a cricket match, when the countrymen proved the victors. The proceedings were much enjoyed by the large assemblage.

— "G. A.," writing to us on *PYRETHRUM AUREUM LACINATUM*, states that in their early stage the plants were more quick in growth than the familiar Golden Feather. They were planted out in June in much better condition than Golden Feather, not from any greater care being taken of the young plants, but clearly from the great freedom of growth of the new variety. Both varieties are beautiful, yet their beauty is of a different description. Golden Feather is deservedly popular from its close compact dwarf habit and bright yellow foliage. The Cut-leaved on the other hand has very finely-divided foliage, and though it is perfectly golden in colour, its many divisions cause the golden tint to be softer, less bright, contrasting only moderately well with *Lobelia*, but admirably with bolder foliage, as *Iresine* Herbstei and massive succulents.

— MR. KING in his volume entitled "The Southern States of North America," observes that "the fitness of Florida for the growth of TROPICAL and SEMITROPICAL FRUITS is astonishing. Not only do the Orange, the Lemon, the Lime, and the Citron flourish there, but the Peach, the Grape, the Fig, the Pomegranate, the Plum, all varieties of berries, the Olive, the Banana, and the Pine Apple grow luxuriantly. Black Hamburg and White Muscat Grapes fruit finely in the open air; the Concord and the Scuppernong are grown in vast quantities. The Guava, the Tamarind, the wonderful Alligator Pear, the Plantain, the Cocoa Nut, and the Date, the Almond and the Pecan, luxuriate in southern Florida and the Indian River country. Within these boundaries a tropic land, rich and more strange, will one day be inhabited by thousands of fruit-growers, and where beautiful towns and perhaps cities will spring up. A good tree will bear from 1000 to 3000 Oranges yearly. Some trees at Mandarin have produced 5500, many of the Oranges weighing nearly a pound. One young grove on Indian River, with 1350 trees, produced in a season 700,000 Oranges. They were sold for \$25 to \$68 per 1000 case, and netted to its owner over \$20,000. Col. Heart's grove nets him from \$12,000 to \$15,000 yearly. Dr. Moragne has a grove that nets him over \$20,000 per annum. Only one man is required to attend one of these groves, who requires one or two negro men to help to pick and market them. The culture of Oranges will certainly become one of the prime industries of Florida."

HOYA CARNOSA.

It may perhaps interest some of your amateur readers to know that this plant succeeds perfectly as a greenhouse climber. There is a plant here, trained to the back wall of a cool greenhouse, which occupies about 25 square feet of wall, and I have to-day counted 105 fully expanded trusses of bloom upon it, besides numerous other trusses in all stages of development. This plant receives little care or attention. It is growing in a narrow border composed principally of loam. It has water whenever the other plants in the border appear to require it, and this, with an occasional tie or the cutting away of a

rampant shoot, constitutes the sole attention it receives. The ventilators of the house in which it is growing are open to their full extent day and night during the summer months, and in winter the temperature often falls to within a degree or two of the freezing point, yet the plant flourishes admirably, and the last two seasons has made sufficient growth to cover double the space it now occupies, but which is all that can be afforded for it. Its wax-like flowers are extremely beautiful.—A. E., *Hicanton Satchville*.

HYDE PARK.

NOWHERE have flowers and flower beds so many admirers, nowhere are they better appreciated, and nowhere are they more skillfully arranged and better managed than in the London parks. The high-class mode of decoration adopted in all the chief parks render them much more than pleasant places for the promenade of the million, although that is their chief object—an important object, for the issues resulting when art in its higher forms and Nature in her most attractive aspect are blended have a much deeper effect than merely gratifying the eye. The London parks afford lessons in garden decoration which are learnt by passers-by of every grade, and hundreds of gardens are consequently made more attractive and homes more enjoyable by the artistic employment of plants and flowers.

Geraniums continue, and are likely to continue, to be the most popular of bedding plants. In Hyde Park there is a choice selection of them. Varieties new and old are employed, and the public can see for themselves which are the more likely to satisfy in private gardens. A great advantage is that every sort is legibly named, which renders the beds additionally interesting. The Geranium beds commence near the Marble Arch, and are continued along the narrow eastern enclosure next to Park Lane. The Geraniums have passed their best, but are still beautiful, and a glance at some of the varieties may be useful during this the period of propagating. Some of the beds are partially shaded by neighbouring trees, and this with close planting, rich soil, and a season when showers have been tolerably frequent, and intense heat has not prevailed for many consecutive days, have promoted the free growth of the plants and somewhat diminished their season of beauty.

Amongst the crimson-scarlet varieties General Outram and Wellington are two of the finest bedders. They are free growers, form a tolerably level surface, and produce numerous and fine trusses of extremely rich colour. A trifle lighter in colour and brighter is Sir Henry Stanhope; this is a very fine bedder, compact in habit, free, and brilliant. Brutus is very good, but not equal to those named, and Milton of the same type of colour is irregular in growth. The older variety Bonfire is a blaze of beauty, and must not be lightly discarded. It has not large trusses, but they are numerous, and the colour is extremely rich. Of the brighter scarlets Chunder Sen is dwarf and lively in colour. A. Rogers is rather dull and irregular in growth, and Maud Holden is a little shaky. There are no really good pure scarlet beds. As a rosy crimson Amy Hogg is yet good; but the best bedder of this colour is Fire King, a dwarf-growing Noregay variety with a profusion of fine trusses all of the same height. Pioneer, a dwarf variety with cherry crimson flowers, is very distinct; it is more novel, perhaps, than effective. Different in tint to any of those named is Jealousy, a slight tint of yellow playing on the soft scarlet petals is very pleasing. It has well-formed flowers, but evidently requires rather poor soil and an exposed sunny position to bring it to perfection as a bedder. It is a free grower, but apt to become a little irregular in over-rich soil; it is much admired by visitors. Amongst the lighter colours Amaranth, rosy lilac, is very good; and of the rosy pinks Mrs. Gibbons is certainly one of the best. Mrs. Turner, Mrs. Holden, Lucy, and Princess of Wales are very fine, surpassing Sibylla, Triomphe, and Master Christine. There is not a good bed of white Geraniums, La Vestale being irregular in growth, and the only good white with salmon centre as a bedder in the Park is Maurice Bernadine, which is dwarf and floriferous. The Geraniums are surrounded with a ring of blue Lobelia edged with Golden Feather.

A few mixed beds afford an agreeable change, such as Iresine Linden and Gazania splendens; silver variegated Geraniums and dwarf Ageratums; and Iresine Linden and golden-leaved Geranium. Some beds have a ring of Mesembryanthemum and an edging of Lobelia, but the Mesembryanthemum is too dwarf for such a position. The fine specimens of Bays, Palms, and Cordylines disposed down the centre of the lawn add con-

siderably to the beauty of this portion of the Park. It is here, too, where the "carpet beds" are to be seen, and it is indisputable that they are more lasting in beauty than the Geraniums. The artistically arranged beds of dwarf foliage plants will be attractive for weeks to come, and long after the Geraniums have assumed a seedy and weedy appearance.

The carpet beds in this Park have never been better than this year, and their condition reflects much credit both on those who have designed the patterns and those who have "worked them out." In some of the beds the designs are bold and simple, in others more intricate and flowing. Some of the beds have flat smooth surfaces, others have raised lines and figures and sunken panels. It is useless attempting to describe minutely what is indescribable, but an outline of the general character of some of the beds may be briefly submitted. One of the "bold and simple" beds has squares and inter-fitting triangles of Coleuses on a ground of Golden Feather. The bed is margined with Alternantheras and edged with Echeverias. The next bed is more elaborate. It has a centre of Iresine Linden somewhat in the form of a Maltese cross, scrolls of Alternantheras amena and paronychoides on a groundwork of variegated Mesembryanthemum, and angles of green Sedum, edged as before—very chaste. Another bed is of a Turkey-carpet pattern, the centre and edge being formed of the green Gibraltar Pennyroyal (*Mentha Pulegium gibraltaricum*), the greater portion of the bed consisting of an intricate design of Alternanthera on a groundwork of Golden Feather and Sedum glaucum. The next is a panel bed, the raised portions being composed of Pachyphyton, Mentha, and Iresine, with sunken panels of Leucophyton Browni, the whole having a band of Golden Feather and an edging of Lobelia. It is a novel and effective bed, somewhat marred, however, by the Lobelia. Another panel bed has an elevated design of Iresine; raised cushions—diamonds and circles 18 inches in diameter—of Mentha; sunken panels of Leucophyton and Antennaria tomentosa, and bands of Golden Feather and Alternanthera—effective. Near it is a bed having central squares of Golden Feather surrounded with interlocking bands of two distinct Alternantheras; angles of Antennarias, a band of Lobelia (too tall), and an edge of Echeverias—distinct and novel. The next bed represents a flowing tracery of Golden Feather and Alternanthera, the bands being about 6 inches wide; angles of Sedum acre elegans, sunk panels of the Cobweb Houseleek, and an edging of Alternanthera—very chaste. Such are a few typical beds. They are large and the plants are in excellent colour and condition, the only failure, perhaps, being the Lobelia, which is not dependable for this artistic and elaborate style of ornamentation. The visiting public linger over these beds admiring and criticising. The style is undoubtedly popular and is well carried out.

Along the Knightsbridge side of the Park comes another change, and an agreeable one. The long stretch of irregular lawn—green and in perfect order, dotted with fine trees at irregular intervals and having isolated specimens of Yuccas, Palms, and Cordylines, with mop-headed Acacias (*Robinia inermis*) and evergreens, a few groups of subtropical plants, and here and there bright beds of Geraniums—has a cool refreshing appearance, which is very acceptable after the glare of the Geraniums and the trim formality of the carpet patterns. This is a delightful and enjoyable portion of the Park, but not more so than the tropical forest scene known as the Dell.

This is the western extremity of the decorations, and is a worthy finish to the varied attractions of the Park. From the walk fronting the Dell a sloping lawn 5 or 6 yards wide descends to the water—a moat-like stream 12 or 15 feet wide, which forms a semicircular boundary to the semitropical grove. On the near bank of the stream the Royal Fern with Grasses and Sedges luxuriate. On the opposite bank are bold Ivy-clad knolls surmounted with Monstera and Phormiums. Beyond is an irregular expanse of turf of triangular shape, the ground rising almost abruptly from the base to the distant apex. Sheltered by surrounding banks of Rhododendrons and shaded by the thinly disposed trees, the "tropicals" are artistically grouped. Prominent is a grand specimen of the Fan Palm and a few scattered specimens of Phormiums, Monstera, and other isolated specimens. Near the sides are bold groups of Musas and Cannas, and in the centre a grove of towering Cordylines. This dell, viewed from any point—from the lower ground looking upwards or from the higher looking downwards—is extremely beautiful and contributes greatly to the attractions of the Park.

Several beds which were formerly in the interior of the Park

have been turfed over, and the change is an improvement. The fringe of flowers noticed on the sides of the Park is sufficient, and a large expanse of grass in the interior is more in keeping with the nature of the Park, and renders the gardenesque portion more distinct and decided. Never has the Park looked better than during the present season; and the chief authorities at the Board of Works, Mr. Gibson the Superintendent of the Park, and Mr. Chamberlain the practical Manager, are to be congratulated on its excellent condition.—J. W.

PENTSTEMON CYANANTHUS (AZURE-FLOWERED PENTSTEMON.)

A MOST beautiful blue-flowering perennial kind, bearing a spike of bloom more than a foot long. It is an inhabitant of the upper valleys of the Plate River, in the Rocky Mountains, where seeds were collected by Mr. Burke. From these seeds

Fig. 35.—*Pentstemon cyananthus*.

plants were reared by Messrs. Lucombe, Pince, & Co., in whose nursery at Exeter the plants flowered in the open air in May, 1849. The species is quite hardy, and a great acquisition to our flower borders. It is desirable to have a succession of young plants always on hand, which may be raised by cuttings early in the summer, and which should be sheltered in a frame during the winter, but with as much exposure as the weather will allow.

* ARTIFICIAL MANURES FOR ROSES.

I REGRET that "PACER'S" inquiry how much mineral manure I would apply to Roses at this season should have accidentally remained for a week unanswered. He must remember, in the first place, it is an experiment. As I said before, I have no direct experience with Roses, though I have with other plants. Trusting to this analogy I would mix intimately three parts of best superphosphate of lime with one part of muriate or sulphate of potash, and of the mixture I would sprinkle a quarter of a pound round each Rose, say within a radius of 20 inches from the stem. If rain does not come to wash it in water should be applied slowly and repeatedly. A little of the lime will remain in any case on the surface undissolved. If the soil is poor and the Rose not succulent in growth, half an ounce of nitrate of soda or of nitrate of

potash (saltpetre) might be added to each Rose; but as a rule I would defer this last ingredient till spring, when that quantity might be given several times in conjunction with the mineral manures above referred to.

The controversy between "A RETIRED GARDENER" and myself may now be regarded as closed, neither, I daresay, having expected to convince the other, but having written for the judgment of the public. But as "A RETIRED GARDENER" asks me what I think of 80 tons per acre of horse manure applied by a market gardener, I will only say that I do not doubt it was a very proper quantity for the crop to which it was given and the crops which would follow. But the subject of discussion has been guano and nitrate of soda, which involve totally different principles and practice.—J. B. K.

DISTINGUISHED BOTANICAL TRAVELLERS.

No. 2.

JOHN FRASER.

AMONGST those who have enriched our gardens by their discoveries in other lands few have been more persevering and more successful than this celebrated traveller. He was the man to whom Europe is indebted for the magnificent hybrid *Rhododendrons* that of late years have caused the "American grounds" of the Old World to heave with a perfect ocean of beauty and grandeur. Who, then, knowing this, could look on such scenes of splendour as are afforded by large collections of these gorgeous shrubs, and not venerate the name of John Fraser? But it was not alone the *Rhododendron Catawbiense* (which is the basis of almost all these hybrids) that he discovered and introduced to this country, it is to him we are indebted for *Andromeda floribunda*, and all that is interesting in *Azaleas*, *Kalmias*, *Andromedas*, *Vacciniums*, *Magnolias*, *Menziesia globularis* and *ferrugines*, many species of *Oaks*, *Pinus*, *Phlox*, *Oenothera*, and a list too long to enumerate here, amounting to somewhere about 220 distinct species of American plants, all collected under hardships and privations crowned with less remuneration and with more hopes disappointed than any collector either before or since has ever experienced. He started on his perilous undertaking single-handed and alone, with no society to support and no patron to encourage him; his labours were labours of love, and his reward—a too-much-forgotten name.

This extraordinary man was a native of Scotland; he was born in 1750 at Tomnaclloch, near Inverness. His father was a highly respectable farmer, and occupied the same land which his ancestors had done for many generations previously. How his early life was spent cannot now be ascertained, but it is supposed that he arrived in London about the year 1770, being then in the 20th year of his age. During the early part of his life he laboured under a delicate state of health, being, in fact, affected with consumption. Finding his health declining, his friend, Admiral Campbell, then commanding the Newfoundland station, induced him to accompany him to that colony, with the view of arresting the progress of the disease; he accordingly left England, and arrived in Newfoundland in 1780. He had not been long there before he found himself thoroughly restored, and he devoted his time to exploring the botanical productions of that country. He was always an ardent lover of plants, and here he found an extensive field and new objects for admiration, among which he remained till 1784. He had now acquired such a taste for discovery, and such a habit of restlessness, which so prevented him from settling down to any fixed occupation, that in 1785 he set out on a journey to the Southern States of North America, and during two years he was engaged in investigating the botany of that country, which resulted in many valuable additions being made to the collections at home. He again left England in 1788 on a second expedition to the Southern States, and this was attended with as great success as the former, for on this occasion also he sent home many new and valuable plants. While on this journey he formed an intimacy with the elder Michaux, who had then just entered on his labours as collector for the French Government.

Between the years 1789 and 1796 he twice visited North America, still with the same object in view, and still with the same success. During this period he traversed the Alleghany Mountains, penetrated into several of the Indian settlements, and exposed himself to an amount of privation and hardship such as few other men could have undergone. And here, be it remembered, the America of seventy years ago was not the America of to-day; much of the soil that is now traversed by the loc-

motive, and gladdened by the joyful sounds of progress and civilisation, was then the hunting field of the Indian and the scene of many a bloody conflict. Where now the ploughshare and the pruning-hook pursue their quiet and ennobling course the scalping-knife and tomahawk savagely reigned. Few now can realise what a traveller like John Fraser had then to undergo.

After his return to this country in 1796 he visited Russia, taking with him a large collection of plants, the result of his labours in America. These he submitted to the Empress Catherine, who so highly appreciated their value and esteemed the character of the man that she requested him to set his

own price upon them, which was accepted. After the death of the Empress Catherine he was requested again to visit Russia, when he received commissions from the Empress Maria to supply further collections to the Imperial Gardens of Gatschina and Perlorskoe; and such was the favour with which the imperial court regarded him, that in 1798 an ukase was issued, signed "Paul and Maria," appointing him their botanical collector. This gave a fresh impulse to his untiring spirit, and in 1799 he for the sixth time crossed the Atlantic, accompanied on this occasion by his son John, to prosecute in the Northern and Southern States that discovery in which he had already been so successful. Having on this expedition

Fig. 86.—MR. JOHN FRASER.

penetrated to the far west, it was on the summit of the Great Roa, or Bald Mountain, that he discovered the *Rhododendron Catawbiense*. Speaking of this occasion the son told the writer of this, "I shall never forget so long as I live the day we discovered that plant. We had been for a long time travelling among the mountains, and one morning we were ascending to the summit of the Great Roa, in the midst of a fog so dense that we could not see further than a yard before us. As we reached the top the fog began to clear away, and the sun to shine out brightly. The first object that attracted our eye, growing among the long grass, was a large quantity of *Rhododendron Catawbiense* in full bloom. There was no other plant there but itself and the grass, and the scene was beautiful. The size of the plants varied from seedlings to about 2 feet in height, the habit being evidently diminutive from the high altitude at which they grew. We supplied ourselves

with living plants, which were transmitted to England; all of which grew and were sold for five guineas each."

On the termination of this journey through the States they visited Cuba in 1800, but on account of the war which then existed between Spain and Great Britain they were obliged to procure passports and travel as American citizens. On the voyage they were wrecked on a coral reef, about forty miles from land and eighty from Havannah. For six days they, with sixteen of the crew, endured the greatest privations, until picked up by a Spanish boat and conveyed to land. Through the interest of the American consul they were allowed to proceed overland to Havannah, where they met with the celebrated travellers Humboldt and Bonpland, from whom they received the greatest kindness, and to whom they communicated the nature of their journey. Humboldt relating in confidence to the Spanish Governor that they were Englishmen and bota-

nical collectors, he replied, "Though my country is at war with England she is not at war with the labours of these men." They pursued their course unmolested, visited the mountains of Cuba, and discovered many new and valuable plants, among which was *Jatropha panduræfolia*. Having made his collections they returned to America in 1802, and thence embarked for England, but after being some time at sea the ship sprang a leak, and was obliged to put into Port Masson in New Providence. On arriving in England a greater disappointment awaited Mr. Fraser, for on landing he heard that the Emperor Paul was dead, and the Emperor Alexander refused to sanction the engagement entered into by his predecessor. In the Dowager Empress Maria, however, he met with a friend, for she fully discharged his account, and, in addition, presented him with a handsome diamond ring. When in Russia in 1796 he procured the Black and White Tartarian Cherries, which are sometimes called Fraser's Black and Fraser's White Tartarian Cherries, and introduced them for the first time into this country.

In 1807 he made his seventh and last voyage to America, again accompanied by his son, and again he was successful in many new discoveries, with which the son returned to England, leaving the father to prosecute his discoveries. He again visited Cuba, and in 1810 returned to England. During this last journey he had the misfortune to fall from his horse near Charleston, and broke several of his ribs. From this accident he never fully recovered, and, after forty years of unwearying zeal and activity he died at Sloane Square, Chelsea, in April, 1811.

After his second return to England from America Mr. Fraser established the "American Nursery" in Chelsea, as a receptacle for the plants which he discovered and introduced. This nursery was situate on the east side of the present Royal Military School, and extended over twelve acres.

Thus lived and thus died John Fraser, F.L.S., one of the most zealous and disinterested, and at the same time most successful, botanical collectors which this country has ever had.

CLAYCROSS (DERBYSHIRE) FLOWER SHOW.

THE twentieth annual Exhibition of the Claycross Floral and Horticultural Society was held on the 14th inst. in the beautiful park-like grounds adjoining the residence of Charles Binns, Esq. This has now become one of the greatest exhibitions in the midland counties, and the Show of the 14th inst. was quite equal to any of its predecessors. It was feared that the long-continued depression of trade in the colliery districts would tell against the success of the Show, and that there would be fewer visitors, and consequently the money taken at the gates would be less than usual. However, the state of trade did not affect the Exhibition, for the numbers were on the increase. Last year it was estimated that upwards of 14,000 people visited the tents, and as the money taken at the gates this year exceeded that of 1876, the number of visitors could not have been less than 15,000.

The Exhibition took place under three spacious tents, which formed three sides of a square. The side tents had tables running down the centre, which were filled with plants of every shape, size, and hue, and the benches down each side were devoted to fruit, cut flowers, and vegetables. The end tent was a circular one, and contained a fine collection of plants sent by the Duke of Devonshire from his rich stores at Chatsworth, and also the collections of twenty plants open to nurserymen and gentlemen's gardeners. The exhibitors were divided into five classes, the first, second, and third being chiefly cottagers and farmers, the fourth amateurs residing within twelve miles of Claycross, and the fifth was open to all subscribers of £1 and upwards. Here liberal prizes were provided, for the amount offered in this class alone was upwards of £167.

In the collection of plants sent from Chatsworth, not for competition, were several *Disa grandifloras*, a fine *Anthurium Scherzerianum*, *Dipladenias*, *Bougainvillea glabra*, several fine *Ericas*, and also some excellent Palms and Ferns, including a very fine *Adiantum farleyense*, also the *Ouvirandra fenestralis*, the singular Lattice Plant.

For the collection of twenty plants, including eight stove or greenhouse plants in bloom, six fine-foliage or variegated plants, and six exotic Ferns, for which prizes of £25, £20, £15, £10, and £5 were offered, there were only three competitors. Messrs. E. Cole & Sons of Withington, near Manchester, secured the premier prize with some magnificent plants, including a fine *Statice profusa* upwards of 3 feet in diameter, *Ixora coccinea*, *I. coccinea superba*, a remarkably well-grown plant; several *Ericas*, some fine Palms, *Crotons*, *Cycas revoluta*, and noble Tree Ferns. Mr. Tudgey, gardener to T. F. G. Williams, Esq., of Handwick Grange, near Worcester, obtained the second prize

with some fine *Ericas*, Tree Ferns, a very fine *Pandanus Veitchii*, and some well-grown *Ericas*. Mr. J. House of Peterborough was placed third. He had some very excellent stove and greenhouse plants, such as *Clerodendron Balfourii*, *Stephanotis floribunda*, *Phormium tenax variegatum*, *Croton irregularis*, and some good Ferns.

For the collection of six stove or greenhouse plants in flower Mr. Ward of Riddings House was first; Mr. Reynolds of Oyston Hall second; and Mr. Egglestone, Claycross, third. Mr. Ward had some excellent plants in his collection, including *Plumbago capensis*, a very fine *Statice profusa*, a capital *Ixora Williamsii*, two fine *Ericas*, and a *Dipladenia amabilis*. Mr. Ward was also first for ornamental or variegated-foliage plants, six distinct species; and in the group of not less than twenty plants arranged for effect on a table 3 feet wide, Messrs. E. Cole & Sons were first; Mr. Beard, nurseryman, Stonegraves, Chesterfield, second; Mr. Ward, Riddings House, third; Mr. John House, Peterborough, fourth; and Mr. Proctor, Chesterfield, fifth. In the smaller collection of plants Mr. Ward had the lion's share of prizes.

Of hardy fruit there was a very creditable display, Gooseberries and Currants being fine and abundant. Mr. Froggett, gardener to the Hon. F. C. G. Hunlake of Wingerworth Hall, won the first prize with a fine collection of hardy fruit, but the crowd was so great that we could not get near the stand to examine the dishes. For the best collection of hothouse fruit Mr. Ward of Riddings House was first, and at the distance we could see some fine bunches of Grapes on the tray. For black and white Grapes Mr. Ward was the first with excellent bunches of Muscat of Alexandria and Black Hamburg, the two latter bunches weighing about 9 lbs. No other Grapes were worthy of notice.

Of Roses there were some good stands. For eighteen distinct varieties Mr. House of Peterborough came in first with a magnificent box, and Mr. Frettingham of Beeston was a tolerably good second. There were also boxes of twelve and sixteen distinct sorts shown, which contained some noble specimens. Of Dahlias there were some excellent stands, those sent by Mr. Haslem of Hardstof being specially noteworthy. Hard bouquets and dinner-table flower stands were well done. The flower-garden designs came in for a large share of attention by the visitors, but the barbarity of the arrangements almost gave us the headache. Marigolds were specially well grown, as were also the Hollyhocks.

Of vegetables there was a grand assortment, Potatoes being fine in quality and clear in the skin. Upon the whole the generality of the exhibits were good, and the Show in all respects was a great success. All praise is due to Mr. Stollard, the Secretary, for his arduous labours in bringing about such satisfactory results.

WARDIE HOUSE,

THE RESIDENCE OF MISS HOPE.

THIS is situated on the seaside and about three miles from Edinburgh. The house and pleasure ground cover a space of two acres surrounded by a high wall. The view from the house is beautiful. The Firth of Forth, and the Fife coast, and the distant hills afford a fine subject for an artist. The flower plots are laid out on the turf. Many borders are filled with Roses and all sorts of spring, summer, and autumn-flowering plants, and I may say there is not such another choice collection in the neighbourhood of Edinburgh. The plots in the grass are chiefly filled with hardy plants. Some of the figures are divided into patterns with dwarf Thyme, Heaths, &c.; some are filled with the scarlet Phlox Drummondii, *Cuphea platycentra*, *Lobelias*, &c. One plot took me very much by surprise: it was a circle, and filled with *Orchis maculata superba* and *Spiræa Filipendula plena*, and the contrast between the white and purple was very effective. Miss Hope has between one and two hundred plants of that beautiful *Orchis*. The spikes are very strong, and the flower part of them is upwards of 6 inches high, and it is worth going a long way to see. This plant is very scarce about Edinburgh. I never saw it till last year. The common *O. maculata* I have seen forty years ago, and it is worth growing as a variety. I saw at Wardie a fine spike of *Yucca gloriosa*, one of the best I ever saw. From top to bottom of the flowers it is 4½ feet fully. Miss Hope grows a great quantity of Hellebores, some of them very rare. Taking the place as a whole it is far more interesting to me and many others than a modern flower garden in all its glory. The latter comprises twenty to thirty different varieties, the former hundreds. There are no forcing houses, only a greenhouse for Geraniums, &c.

To persons interested in hardy flowers Wardie is worth seeing, and Miss Hope is most courteous and affable to any respectable person who is fond of flowers; and I never met

with any lady who knows plants so well and very few gentlemen. I never go there but I must let her know, and if she is not engaged is sure to come out and walk round her flowers, and if I look at a plant she is sure to ask if I will accept of a part of it. Outside the pleasure ground in a field there are nearly two acres of ground for fruit and vegetables, and this appears to me a far better arrangement than having a hotch-potch garden with vegetables, fruit, and flowers.—J. ADDISON, *Ormiston, Edinburgh.*

NATIONAL CARNATION AND PICOTEE EXHIBITION.

WHEN I sent a few notes and prize list of the Show in the Botanic Gardens, Manchester, I stated that some of the growers were not ready at all, and none of them at their best; it was therefore decided amongst the growers to hold another Show later, and for this purpose a large room in the centre of the city was engaged. Thursday the 16th was the day fixed, and a really fine exhibition was the result. Taken as a whole it was thought to be the best ever held by the Society. The flowers exhibited gave evidence of careful culture, most of them being large, full, and beautifully marked. The same schedule was retained as on the previous occasion. Class A is for twelve distinct Carnations. It will not be necessary to give a list of the names, as the best varieties have been so often quoted in previous numbers. Mr. Ben Simonite of Rough Bank, Sheffield, was first, Mr. Jonathan Booth of Failsworth second, and Richard Gorton, Esq., The Woodlands, Eccles, third. In the corresponding class for Picotees Mr. Simonite was first, Mr. Booth second, and Mr. T. Mellor, Ashton-under-Lyne, third. The next class is for those whose collection does not exceed four hundred pairs, twelve Carnations, nine at least dissimilar. The first prize was gained by Mr. Gorton; Mr. J. Chadwick of Dunkinfield second, who held the same relative position in the class for twelve Picotees. In the class for growers whose collections do not exceed 150 pairs Mr. Wm. Slack of Chesterfield gained the highest award for six Carnations, and Mr. Wm. Taylor of Middleton the second. For six Picotees the honours were reversed, Mr. Taylor being first and Mr. Slack second.

Come we now to the classes, which is always a most interesting part of the exhibition. In the Scarlet Bizarre class of Carnations Mr. Booth was first, second, third, and fifth, and Mr. Simonite fourth. In Crimson Bizarres Mr. Simonite gained all the five prizes—a sufficient testimony to the high quality of the flowers he has introduced. In Pink and Purple Bizarres Mr. Simonite was first and third, Mr. Mellor second, Mr. G. Rudd of Bradford fourth, and Mr. Booth fifth. In Scarlet Flakes Mr. Booth was first, second, and third, Mr. Simonite being placed fourth and fifth. In Rose Flakes Mr. Simonite was first and third, Mr. Booth second, Mr. R. Gorton fourth, and Mr. Rudd fifth. In Purple Flakes Mr. Simonite was first, second, and third, Mr. Booth fourth. In Picotees the best heavy-edged Red was staged by Mr. Mellor; Mr. Simonite second, and Mr. Booth third, fourth, and fifth. In light-edged Red Mr. Simonite was first, Mr. Gorton second, Mr. Booth third and fourth. In the heavy-edged Purple class Mr. Simonite carried off the first, second, third, and fourth prizes, and Mr. Mellor the fifth. In light-edged Purple Mr. Simonite was first and second, Mr. Booth third and fourth. In heavy-edged Rose or Salmon Mr. Simonite was first, Mr. Gorton second, Mr. Mellor third, Mr. Booth fourth, and Mr. W. Bradshaw fifth. In light edged Rose or Salmon Mr. Simonite was first, the remaining prizes being won by Mr. Booth. The premier Carnation in the Exhibition was a grand specimen of Admiral Curzon (Easom) from Mr. R. Gorton. The best Picotee was a very perfect bloom of Mary (Simonite) from Mr. Booth.

I am indebted for the above list of prizes to R. Gorton, Esq., who states that the Show was a most satisfactory one, there being two long tables well covered with blooms. Another correspondent says that some of Mr. Simonite's seedlings were grand. It is very disheartening to him to feel that very possibly many of them will be killed by the smoky sulphur-loaded atmosphere of Sheffield before they can be introduced to the public.

Notwithstanding all that has been said about the greater interest taken in florist flowers north of the Trent, it does not appear that the number of exhibitors was so large at the northern shows as they were in London, nor do they stage a greater number of flowers. I hope that next season some of the great societies, such as the Royal Horticultural and Royal Botanic, will include florist flowers in their schedules and arrange a goodly number of classes for them. Auriculas about the 20th of April, Tulips for the 20th of May, Pinks the 20th of June, Carnations and Picotees about the 20th of July, Gladioluses and Phloxes the 20th of August, Dahlias the 20th of September. The 20th of October will rather puzzle the florist, but the noble Chrysanthemum will do well to fill up the 20th of November. If those in power will kindly note the above dates it will save some trouble afterwards. Prizes for Carnations and Picotees

have been offered the first week in July, and on one occasion on the 30th of June. It is not possible to show good flowers at that time, unless the season should be exceptionally early.—J. DOUGLAS.

STANSTEAD PARK AND RUTLAND PARK NURSERIES.

At the metropolitan shows and at the meetings of the Royal Horticultural Society the firm of Messrs. John Laing & Co. is frequently represented, and always in a creditable manner. The senior member of the firm, Mr. John Laing, knows, as the popular phrase goes, a "good thing" as well as most of his fellows, and of some particular plants few have a better selection than he has. Of Phloxes, for instance, there is no better collection in the south than at Stanstead Park, and of Golden Bicolor Pelargoniums some of the first varieties of the day had their origin in this nursery. These with Caladiums, Pentstemons and Tuberous Begonias are, perhaps, the specialties of the nursery, which, however, is very general in its character, and is furnished with selections of most of the popular families of plants for in and out-door decoration. Fruit trees and Roses are also largely and excellently grown by the firm.

The Stanstead Park Nursery, the head-quarters of the firm, is not extensive. It may, perhaps, consist of half a score acres of land which is not of the most fertile nature; hence all the fruit trees, Roses, choice shrubs, &c., are grown in the Rutland Park Nursery—the "head-quarters," containing plantations of coarser trees and crops; also glass structures and collections of plants in pots. There are about a dozen span-roofed houses besides pits and frames, and all full. One house is wholly occupied with Tuberous Begonias, to which Mr. Laing has latterly been devoting special attention. The double varieties, Gloire de Nancy, Balsaminiflora, and Lemoinei, are growing and flowering freely, the flowers appearing to improve as the plants arrive at maturity. The single variety, Paul Masuriel, is a giant in its family, stately in growth and with flowers 3 to 4 inches in diameter. Oriflamme is very bright and free, as also are William Pfätzer, Acme, and many others. Unnamed seedlings are growing by thousands, some of the flowers expanding being of considerable promise. A new house—a low, light, span-roofed structure, 70 feet long by 20 wide, is occupied by Vines in pots ripening their canes close to the glass, Caladiums and other fine-foliaged plants, the shade of the Vines just suiting the Caladiums. The stock of these plants is very extensive and varied. There is a demand for them in summer for furnishing purposes, but they are principally grown for distributing in a dry state during their dormant period. The new varieties—Madame Alfred Bleu, Aristide, Souvenir de Madame E. André, Madame Laforge, Pyrrhus, Romeau, and Paul Veronese—are great acquisitions; and not much less beautifully marked, veined, and marbled are such sorts as Felicien David, Lalagii, Louis Duplessus, and Madame de la Deransaye. The golden varieties—the royal group—Princess Royal, Princess Teek, and Princess Alexandra are also attractive. Another house contains Palms—three thousand small plants of *Areca lutescens*, also large batches of *A. rubra*, *A. aurea*, small *Dicksonias*, *Lomarias*, &c., and in an adjoining structure is a fine stock of the distinct Maiden-hair, *Adiantum macrophyllum*. The plants have been grown without the aid of artificial heat and are in superb health. In this house several plants of *Todea (Leptopteris) superba* are becoming established after their long journey from the Antipodes. The plant stove is filled with *Gardenias*, *Crotons*, *Dracenas*, and a general collection of ornamental-foliaged plants. *Dracena hybrida* (Veitch), a beautiful plant when well grown, is in excellent condition. A large house is devoted to Cucumbers. Stanstead Rival—this is a very fine Cucumber, the result of a cross between Telegraph and Blue Gown. It is of large size yet not coarse, prolific, of a fine dark green colour, smooth, straight, and of excellent flavour. The bed containing the roots is surface-dressed with spent hops, which arrest evaporation and afford a medium which the roots apparently enjoy. Such is a brief sketch of the houses and their contents. The collections of plants outside demand notice, notably the Phloxes, Pentstemons, and Golden Bicolor Pelargoniums.

PHLOXES.—Extremely fine are these; in fact, no plants in their season, and which can be grown so easily, can produce a more imposing effect. They are striking by their bold spikes of handsome flowers, yet without the slightest approach to gaucheness. Their colours are most varied, ranging from

purplish crimson to pure white, almost every intermediate shade being represented, many of the varieties having shaded petals and distinct dark centres, and their perfume is delightful. The plants are grown in 8-inch pots placed in the open air, and receive much the same treatment as Chrysanthemums—minus, of course, stopping their shoots. No attempt has been made to grow large specimens similar to some that Mr. Laing has exhibited in previous years, but the object has been to produce medium-sized handy decorative plants, such as would fittingly adorn conservatories, corridors, and halls, and such plants that may be equally well grown in any well-managed garden. The plants now flowering so finely were in quite small pots last year at this time, and only good soil and ordinary attention in watering them have been given to bring them to their present excellent state. Such plants are worthy of being extensively grown, and could not fail to add to the attractiveness of any conservatory during the summer months. They contrast admirably with ornamental-foliage plants, and afford an agreeable change to Geraniums, Fuchsias, and Achimenes. Phloxes in pots require no “shelves near the glass” for growing them—no shading nor fumigating, a timely stake to each plant and good support being the chief and simple essentials of culture. In borders they are beautiful, but to have them in fullest beauty a few should be grown in pots, and no summer-flowering plants will give a better return for the necessary labour bestowed on them. A few of the finest varieties are the following:—Valentin, rosy salmon; Gustave Duchesne, purplish crimson; Alfred Crousse, salmon suffused with purple; La Croix de St. Louis, lilac, edge of petals white; Madame Antin, crimson; Victor Lemoine, rich rosy salmon; The Duke, lilac, shaded rose; George Grieve, rosy salmon; Man of Kent, rosy carmine; Mons. Crousse, rosy crimson; Mons. Malet, lilac, white centre; Mons. Taillard, reddish salmon; Mrs. Dombrain, white, crimson eye; Queen of Whites, French white; White Lady, very pure; Souvenir des Termes, white and purple, fine; J. M. Purvis, white, crimson eye; Delicatum, white and lilac; and Madame la Comtesse de Turenne. Those named are all superior; only the prevailing colours are given, but most of them have distinctly coloured eyes. They all belong to the decussata or late-flowering section, and are more vigorous in habit, more lasting in beauty, and more generally satisfactory, at least in the southern counties, than are varieties of the suffruticosa or early-flowering group.

PENTSTEMONS.—Of these there is an excellent collection, and not many autumn-flowering plants are more elegant in habit and more beautiful for border decoration; they also produce an excellent effect when grown in pots. The flowers of some of the varieties are almost as large and quite as richly spotted as Foxgloves, and the colours are extremely varied, including crimson, scarlet, purple, lilac, rose, and white. Although not quite hardy they are as easily cultivated as Phloxes, their chief requirements being good soil, an open situation, a few stakes, and an adequate supply of water. Small plants struck in the autumn and wintered in small pots in cold pits and frames flower freely and attractively during the following season. They are admirable for large beds, lines, and mixed borders in gardens, and these are many, where flowers are particularly desired from August until November, and where Geraniums, varied as they are, are not considered the “be-all and end-all” of garden ornamentation, and where “carpet beds” are not regarded as the climax of the gardener’s art. Pentstemons are effective without being formal, elegant in habit, sprightly, and cheerful. A few excellent varieties are here named—Count Munster, white throat; James Rothschild, crimson purple, white throat; J. H. Stanley, red, white, and claret; Lady Coutts Lindsay, pure white; Lord Carington, purple, peach, and white; Mrs. G. Patrick, bluish purple, white throat; Novelty, pink, blotched crimson; The Bride, white and rose; W. E. Gumbleton, purplish rose and white; W. M. Dolben, purplish red and white; William Paul, rosy crimson; Black Knight, maroon and white; Brilliant, rosy purple and white; Emilie Chaté, soft rose and white; and Mrs. J. Douglas, claret and white. The above are established varieties. Some fine newer sorts are Lord Salisbury, Midhat Pasha, Dr. Masters, Raphael, Maréchal MacMahon, Richard Wallace, Empress of India, Robert Whyte, and Chloris.

GOLDEN BICOLOR GERANIUMS.—Some years ago Mr. Laing set up an ideal standard to be attained in the foliage of this very effective section of a popular family of plants, and he has about attained it. Stout leathery foliage of circular outline, clear zone and margin, and sharply defined and rich contrasting colours, were the objects which have been steadily kept

in view, and the result is varieties which make their way out of the nursery as fast as they can be propagated. No Geraniums are more easily cultivated than these, for they grow as freely as the green-leaved kinds, while their brilliant golden colours and rich chestnut zones render them singularly gay. Their chief requirements are plenty of light and air, with good soil and support to keep their roots moving. Open-air culture, with only slight shelter in extremely inclement weather, is the mode adopted during the summer to bring the plants to perfection. They are now being partially rested and matured preparatory to being pruned and propagated. Some of them are highly effective bedding plants, notably Maréchal MacMahon. This is the best of all for beds, the growth being free yet compact, and the colours bright and distinct. The newer variety Exquisite is also very telling when planted out. This is a splendid variety, and if surpassed by any it is by John Jenner Weir, which is strikingly uniform and rich in colour. Japan is a fine new variety, as also are Australian and Richard Thornton. The Czar is the darkest of all. The Shah, Warrior, Prince Bismarck, Count Munster, Mrs. F. J. Horniman, and W. E. Gumbleton are all distinct and good.

Besides the plants named there are collections of nearly all other flower-garden and greenhouse plants, including a considerable stock of the new Chrysanthemum Golden Empress of India, which is an admirable grower and very sturdy in habit. Another plant having its “home” in this nursery must not be passed in silence—Fuchsia Lord Beaconsfield. It is the result of a fortunate cross between *F. fulgens* and one of the garden varieties, and has received a first-class certificate from the Royal Horticultural Society, also at the Royal Botanic Society and at the Crystal Palace. It is a distinct and striking variety, with immense flowers with rosy carmine tube and bright carmine corolla. It is a strong grower and most profuse and persistent bloomer, rendering it valuable for decoration, and it can scarcely fail to become very popular as a “market plant.” Yet another plant worthy of note is a new double *Petunia Souvenir de Chiswick*. It is rosy purple striped with white, and has crimped petals, and is extremely effective.

RUTLAND PARK NURSERY.—This is twice the size of the Stanstead Park Nursery, and the soil and situation are specially suitable for the cultivation of fruit trees and Roses, both of which are extensively grown. Finer trees—standards, pyramids, and trained trees of Apples, Pears, Plums, Apricots, and Cherries—could not be desired than the robust short-jointed stock in this nursery. Roses are grown by thousands, and thrice the usual number are being budded this year, so great has been the demand. That rich dark Rose Louis Van Houtte is unusually brilliant on this soil. Perhaps the finest bloom of it ever exhibited was staged by Mr. Laing at the Bickley Show. There is a “great run” on this variety, also on Belle Lyonnaise, which has all the good properties of Gloire de Dijon with greater purity of colour. All the most popular varieties of Roses are extensively grown, and the second is a fine one. Ornamental trees and shrubs also thrive well; indeed, the nursery is an excellent one, and is in capital order, and a meed of praise is consequently due to the foremen of the firm—Mr. Badman at Stanstead Park, and Mr. Wakelin at Rutland Park.—VISITOR.

FLOWER FARMING IN FRANCE.

In the south of France the Jasmine is cultivated in enormous quantities for perfumers’ use. The cuttings are planted in rows nearly 3 feet apart and 2 or 3 inches from each other; during the first year vegetables of certain kinds are grown between the rows. In the second spring the Jasmynes are fit for grafting. Ordinary cleft grafting is practised, the stocks being headed down to an inch or two above the soil. A good workman, aided by a woman to tie the graft, will work one thousand to two thousand Jasmynes a day, the man earning 5 francs, and the woman 1½ franc a day. In July and August flowers are produced, which must be gathered perfectly dry; and if there is seen during the night to be any danger of rain, men are sent into town at three o’clock in the morning to summon the women to the farm to pick the flowers before the rain comes.

The proprietors of the flower farms at Grasse have the right to use the sewage of the town, which is collected in cemented tanks and distributed by irrigation. One thousand plants of Jasmine in good soil will furnish in the second year after grafting about 120 lbs. of flowers. In subsequent years the production of flowers is very much larger, so that from 3500

to 4000 lbs. are raised on an acre. The general duration of a plantation of Jasmine is from fifteen to twenty years, and the net annual receipts from an acre of well-established plants is about \$450 if the season prove favourable. This industry gives employment to thousands of labourers, both men and women, in the sunny fields of France.—(*Cultivator*.)

BOOKS.

The Royal Parks and Gardens of London, their History and Mode of Embellishment, &c. By NATHAN COLE, Kensington Gardens.

WE are pleased to see that the communications from Mr. Cole published in our Journal have been republished by him in this handsome volume. It is full of useful information on modes of embellishment, arrangement of colours, and the propagation and culture of the plants employed.

Ferns, British and Foreign, &c. By JOHN SMITH, A.L.S. New and Enlarged Edition. Hardwicke & Bogue, London. Small 8vo., pp. xv. and 450, with a plate and very numerous woodcuts.

THIS, as the title implies, is a new edition of an approved and very useful publication. The first edition appeared in 1866, a second in 1876, and we have now a corrected reprint showing that out of the 2646 known and well-distinguished species, exclusive of varieties, we have more than a third in cultivation. We are quite rejoiced to see that the author, notwithstanding increasing infirmity, is still so actively employed about his favourite Cryptogams.

The work consists of a very interesting history of the development of Fern cultivation up to the time when Mr. Smith was no longer able to carry on personal investigations with the microscope, then of an explanation of the terms used in describing Ferns, a matter quite indispensable to the majority of cultivators. To this succeeds the main object of the work—viz., an enumeration of the genera with distinctive characters, to the understanding of which the numerous and nicely executed woodcuts are absolutely necessary, as in cases where the generic characters are founded on the venation it would be scarcely possible, except to advanced botanists, without their help to grasp with certainty the distinctions, even with the aid of the preceding explanatory division. A most useful chapter follows giving the meaning of the generic names, which when once realised are a very great help to the non-classical cultivator. A valuable chapter is added on the cultivation of Ferns, succeeded by a list of authors and books quoted in the work, together with a very perfect index, the want of which so often takes so much from the usefulness of many an excellent work. The specific characters are not given, as it would have increased the bulk of the book so much as to make it very expensive, and where these are desired there are many excellent works to which reference may be had, and which are indicated everywhere throughout the synonyms. From the very nature of the work it is obvious that it does not admit of many extracts; instead, therefore, we make some observations on points to which the author refers but briefly.

But little is known of hybridity in Ferns. The most notorious case is that of *Gymnogramma*, where numerous varieties, if not hybrids, spring up abundantly in cultivation. One of the most singular cases is that communicated from Philadelphia by Mr. Robinson Scott, an apparent hybrid being produced between *Camptosorus rhizophyllus* Lk. (*Antigramma rhizophylla*, J. Smith), and *Asplenium ebenum*. An account of this is given in the Journal of the Royal Horticultural Society, n.s., vol. i., page 137, with figures, together with suggestions for the production of hybrids, which if successful would amply reward the experimentalist. Mr. Smith gives us an account from Leszczyc Suminski of the male and female fructification produced on the prothallus of the germinating Fern. A little nice manipulation might transfer the spermatozoids of one Fern to the female embryo of another, but no one seems, as far as we have heard, to have been successful in such attempts. The position of the bodies in question makes it improbable that the spermatozoids should often be transferred naturally, and that such is not in general the case may be inferred from the fact that the species or forms which from time to time appear in cultivation, always prove either mere varieties or well-known species which have been accidentally introduced. The multitudes of forms which occur in sale catalogues are often mere abnormal conditions, and it is

curious that where a portion of a frond only is abnormal spores taken from that portion will reproduce the peculiar form. Mr. Smith makes some valuable remarks as to the result of halving or quartering the prothallus with the production in each part of a perfect embryo, while in general one only is fertilised; but this is the less surprising since the observation of Dr. Harlow, that a new frond is sometimes produced on the prothallus without fertilisation.

One great difficulty which often occurs in the raising of Ferns from spores is the occurrence of a minute species of mould, which soon spreads over the whole pot and destroys the crop. This will be remedied in many cases, if the first appearance of the mould is watched, by simply sprinkling a little well-washed white quartzose sand on the infected prothalli. The black mould belonging to the genus *Fumago* which occurs on Fern fronds is very troublesome, even in their own native locality. Like other species of the genus it follows the attacks of aphides or cecidi, or where a honey-like deposit is formed on the leaves. A careful observance of the early stages of the fungus will at once suggest the proper treatment. If allowed to gain much head it is very difficult of eradication. Ferns are not troubled much with epiphyllous Fungi in cultivation. *Uredo filicum* is, however, sometimes very troublesome, but mostly to Ferns in open-air cultivation. In such cases the only remedy is the removal of all infected fronds and burning them.

We conclude our remarks with a short extract relative to the black fronds which sometimes occur on Ferns in cultivation, and the more so because it is suggestive as to the too familiar spot in Orchids. "In order to raise vapour a practice prevails with many cultivators to throw water over the hot-water pipes or flues. There is no objection to this provided the air out of doors is warm, but in the winter season it is often done in the evening, in order to counteract the dryness of the air caused by the extra heat of the pipes required at that season. The house then becomes filled with vapour, which coming in contact with the glass of the roof condenses and falls in a shower of cold drops on the plants; at the same time the temperature of the house rapidly falls, thus causing black fronds, spots in Orchids, and such-like complaints." We cannot too cordially recommend this excellent little work to the notice of our readers.

PORTRAITS OF PLANTS, FLOWERS, AND FRUITS.

HOULLETTIA PICTA. Nat. ord., Orchidaceæ. Linn., Gynandria Monandria.—Flowers cinnamon and yellow. "H. picta was discovered by Schlim in New Grenada, along with other very similar species of the genus, collected up to an elevation of 4000 to 6000 feet above the sea. It was first flowered at the celebrated Orchid garden of Consul Schiller at Hamburgh, and later at Farnham Castle, from whence the specimen here figured was obtained."—(*Bot. Mag.*, t. 6305.)

IRIS SPECULATRIX. Nat. ord., Iridaceæ. Linn., Triandria Monogynia.—Flowers lilac and white. "It was discovered in April, 1874, by a Chinese workman attached to the botanical garden of Hong-Kong, on a hill facing the sea between Victoria Peak and Mount Davis in that island. Its general habit is more like that of one of the Cape or Angolan *Moræas* than that of the ordinary *Iris*es of the north temperate zone, but in structure it belongs clearly to the small group of crested *Iris*es, of which *I. japonica*, commonly grown in gardens under Ventenat's name of *I. fimbriata*, is the oldest and best known representative. Of this group seven species are now known, of which two are North American, and the others all Japanese, Chinese, and Himalayan. For the fine living plant from which the present plate was made the Kew collection is indebted to Mr. C. Ford of the Hong-Kong Botanic Garden. It was received in April, 1877, and came into flower immediately after its arrival in this country. The plant is not likely to prove hardy in England."—(*Ibid.*, t. 6306.)

TULIPA UNDULATIFOLIA. Nat. ord., Liliaceæ. Linn., Hexandria Monogynia.—"It was discovered many years ago by M. Boissier on the Tartali-dagh, just above Smyrna, but was only brought into cultivation two years ago by Mr. Elwes. It flowered at Kew early in May of the present year. This spring Mr. Maw has procured a good supply of bulbs from Boissier's original station, which he has distributed with his customary liberality."—(*Ibid.*, t. 6308.)

TILLANDSIA USNEOIDES. Nat. ord., Bromeliaceæ. Linn., Hexandria Monogynia.—"This, the Spanish Moss, Old Man's Beard, and Long Moss of the southern United States and the West Indies, is well described in Sloane's 'History of Jamaica,'

as a 'mossie plant . . . with stalks the bigness of a thread, consisting of a thin skin, whitish, as if covered with a hoar frost, having within that a long tough black hair, like a horse-hair . . . very often a yard long, hanging down on both sides from the branches of the trees they adhere to, being curled, or twining and winding within another, and making a show of an old man's beard (whence the name), or as if they were made to climb, which I never saw they did.' Further on he says, 'It is used to pack up anything which otherwise may easily be broken, as cotton is sometimes made use of with us;' and, again, 'the inward black hairs of this Moss's stalk are made use of by the birds called watchpickets for making their curiously-contrived nests hanging on the twigs of trees.' To this description I have little to add, except that the Spanish Moss is a very widely distributed plant in the hotter parts of America, from Carolina to South Brazil, and on the Andes, hanging in bunches sometimes many yards long from the branches of trees. It has frequently been sent to England as packing for Orchids, but rarely alive, and it is not till quite lately that it has been successfully cultivated at Kew, from plants imported as packing from Jamaica. It now thrives in a damp stove, growing on pieces of Tree Fern and other substances, and flowering in spring." (*Ibid.*, t. 6309.)

PEAR.—*The Peach Pear*.—"We adopt the above name, given to us by Dr. Hogg, for this useful but not very handsome summer Pear, with some hesitation, since other pomological authorities inform us it is not that variety. It was received under the name of Beurré Giffard, but that is certainly an error, the Beurré Giffard being a more highly-coloured pyriform fruit. The Pear ripens about the middle of August. It varies somewhat in shape, some of the fruit examined being slightly narrowed towards the base; the largest measured $2\frac{1}{2}$ inches across near the upper end, and nearly 3 inches in length, both eye and stalk being set in shallow depressions, the eye closed, and the stalk of moderate thickness, and about $1\frac{1}{2}$ inch long. The colour of the skin is pale green, changing to yellow green, and freckled over with light brown spots, russety around the stalk. The flesh is melting and juicy, with a brisk and sweet pear flavour. Altogether the variety is a summer Pear of considerable merit." (*Florist and Pomologist*, 3 s., x., 157.)

PARAFFIN VERSUS ONION MAGGOTS.

LAST year my Onions were very much affected with the maggot, in consequence of which I lost the crop. This season I have beds in three different places, one lot of which began to show symptoms of the maggot. I thought I would try the new receipt, and I made rather a strong mixture of two pints of paraffin to twelve gallons of water, which I poured on one rod of land in the last week of May. In a few days I had expected to see Onions, maggots, and everything else killed, but to my surprise the maggots were as lively as ever. In a fortnight from the first dose I gave them another of the same strength, but all to no purpose. As a proof I drew some Onions, took out the maggots, and immersed them in paraffin for two or three minutes, took them out laid them down, when they went wriggling off very little if any the worse for it. So I believe the maggot will stand a larger quantity than the crop.—A. FAE, York.

CHAPTERS ON INSECTS FOR GARDENERS.

No. 19.

THOUGH my recollections do not extend far back towards the opening of the century, I can perceive a notable difference in the attitude of gardeners towards insects. Insect pests used to be to many such a constant worry that the very name of insect was abominable to them. You might exhibit to them some beautiful moth in the Lepidopterous order we are now considering, and even if assured that the species injured neither flowers, fruit, nor vegetables, they would yet hardly give it a good word. But though our gardeners destroy by expeditious methods far more insects than did their predecessors, with an increase of entomological knowledge there has come about a different feeling, and the majority will admit that the insect tribes by their appearances and motions give a charm to the country scene which one could ill spare, while even in the garden there are some which are positively beneficial and a host of others comparatively harmless.

The latter may be asserted of the lively moths called the "Foresters" and the "Burnets." Why "Foresters" I scarcely know, since they do not particularly haunt forests, though the

caterpillars feed often in sheltered spots; but the "Foresters" themselves love to disport in the sunshine of July. Kensington Gardens had, no doubt, a very different aspect to what it now has when Rennie saw the common Forester (*Procris Statice*), flying on the bank of the Serpentine. Even the Sorrel on which the caterpillars formerly fed seems to have now disappeared from the locality. Occasionally, however, this moth has been seen of recent years hovering over railway banks to the north of London, and in some counties it is rather common. We have two other British species of some rarity. All the three as hauntings of flowers come now and then into gardens, displaying their wings of greenish gold which only expand about an inch. The caterpillars are peculiar, being short, somewhat woodlouse-shaped, and downy or bristly. Also in those gardens near Clover fields do the conspicuous but small moths of the family of the *Zygænidæ* show themselves during the summer, but the caterpillars chiefly feed upon the species of Trefoil and the Vetch called *Heppocrepis comosa*. These caterpillars are not so stout as are those of the *Procridæ*, and mostly yellow-studded with black, the silken cocoons which they spin in June being very observable on the stems of plants, or on palings, in places where they occur. Excepting the Irish Burnet (*Z. Minois*), which has all the wings dull red, the others present a very similar aspect, the blackish green of the wings being adorned with red spots varying in number and also in their arrangement. The commonest of our six species is *Z. filipendulæ*, which shows itself by hundreds on the chalk slopes, as in Kent and Sussex.

A small family, the *Nolidæ*, contains a little moth frequently seen sitting on the leaves of trees in gardens, the fore wings being raised and set out triangularly, and when startled the insect hops rather than flies to another resting place not far off. This rejoices in the name of "The Short-cloak," or in Latin form, *N. cucullatella*. The caterpillar, which is seldom noticed, is dingy brown and hairy; but although it occasionally feeds on Plum trees I have not found it included in any list of our insect enemies. There are three more British species the caterpillars of which seem to give the preference to Oak as their food plant. In the family of the *Lithosidæ*, which follows, there are eighteen British species probably, the bulk of them having a strong family likeness. Many of them furnish illustrations of what is called mimicry, for when the moths are at rest the wings are wrapped round the body, and from their form and usual colouring the eye at first is apt to take one of them for a curled-up leaf or a bit of a twig. On tapping a hedge with a stick during their season we may often notice them dropping to the ground and lying there as if dead, through which device they possibly delude birds that would otherwise seize them. The familiar appellation, Footmen, given to these did, as I suppose, originate in their habit of so falling at the foot of the by-passer. Some of the caterpillars have yet to be discovered, but it may be assumed that the unknown as well as the known are not obstructive to horticultural success, for it seems to be the habit of most to feed on tree lichens, or sometimes on the leaves of the trees on which the lichens are growing. A good representative of the family is *L. complanula*, with smoke-coloured fore wings and pale yellow hind wings, common near London in many places during the summer. Another species presents to view what the old naturalists would have called a "freak of Nature." In this, the Red-necked Footman (*L. rubricollis*), all the wings are black, but the collar is red, thus contrasting with its brethren, which generally exhibit hues of brown, yellow, or grey, sometimes with black markings. The "Footmen" caterpillars are now and then blown off their food plants in high winds during early summer, and they have a dingy appearance, being dotted over with hairs, as if they were trying to cultivate a hairy coating like their relations the "Tigers," but could not quite succeed in so doing.

The moths last referred to afford an example of what is not uncommon in entomology, the transference of the name which has been given to certain prominent species in a family to the whole of that family. It may, indeed, be argued by some hereafter that the name "Tiger" befits the group from the ravenous disposition of the caterpillar, but it doubtless arose from the tiger-like markings of four of the moths. The *Cimnabar* (*Euchelia Jacobæa*) receives its name from the Ragwort, on which it feeds, seldom flying more than a few paces from the common or chalk-pit where the caterpillars have fed up, and where in August they may be noticed busily stripping that plant, offering, one would think, by their black and yellow markings a good bait to birds. Mr. Newman pronounces the

Scarlet Tiger (*Callimorpha dominula*) to be one of the handsomest of insects British or foreign. It is far scarcer than the preceding, yet, like it, is usually found on or near waste ground, where the caterpillar feeds on the Hound's-tongue. Of special importance to us, however, are those Tigers which in their larval state frequent gardens. There are three that are capable of doing some amount of injury, the largest species being the Great Tiger (*Chelonia gaja*), the veritable "woolly bear" of juveniles, and which one often sees in suburban roads performing perilous journeys across, seeking a change of diet probably. The long hairs, which are of a silky hoariness in the adult caterpillar, prove, when the caterpillar has rolled itself into a ball, an admirable protection from birds. It is one of the species that hibernate in the larval stage, and of the numerous changes of skin (amounting to eight, I think), part are gone through in the autumn and part in the spring. The leaves of the Hollyhock are much liked by this caterpillar, but in the garden it will attack various plants. The Buff Ermine (*Arctia lubricipeda*) is not properly a garden insect, but whenever Docks and Chickweed are allowed to grow in the vicinity of gardens the caterpillars of the species readily shift themselves to cultivated ground. This caterpillar is palish in colour with light brown hairs; that of the White Ermine (*A. menthastri*), where the moth is lighter in colour, is much darker, and though this occurs in all sorts of places during the autumn, it is quite at home in the flower or the kitchen garden. Both species spin their cocoons before winter, and these should be looked up and destroyed during the dull season, as every female killed means the extinction of two or three hundred eggs. Most of the moths of this family are sluggish, but not so the Clouded Buff (*Euthemonia russula*), which flies on heaths during the day pretty briskly.

The family of the Lipariidæ contains several species of importance, which may now be passed over with slight mention, as they have been fully spoken of in a previous series of papers. Two species which do much harm on the Continent to the fruit trees are the Gipsy (*Liparis dispar*) and the Brown-tail (*L. chrysorrhæa*). The former of these was once of not unfrequent occurrence in Britain, but it has now become quite a rarity; the latter, though local, is abundant where it is found, yet seems now with us to restrict itself to the Whitethorn and Sloe. Its next-of-kin, the Gold-tail, is generally distributed, and the caterpillar feeds also on the Whitethorn; in disposition, however, it differs from the Brown-tail, for while the caterpillars of *L. chrysorrhæa* construct a common abode in which each brood tarries during bad weather, the individuals belonging to *L. auriflua* construct separate cocoons in the autumn, where each caterpillar leads a hermit life until the spring. The rather inconspicuous imago of the Pale Tussock (*Orgyia pudibunda*) is produced from a gay caterpillar of light green with black bands, having brushes or pencils of hair, which originated the name "Tussock" applied to this and some similar species. Hop-pickers call this caterpillar the "Hop-dog," though it is not limited in its choice of aliment, as it visits numerous trees and shrubs. To this family also belongs that funny little moth, the Vapourer (*O. antiqua*), and if the caterpillar feeds on a great variety of plants in shrubberies and gardens, by that circumstance it is prevented from doing much harm to any one species, for it is not excessively common. The eggs may easily be destroyed in the winter, as they are deposited on the cocoon by the wingless females. It is one of the very few insects that has for centuries braved the noise and smoke of the city of London, breeding on the Limes, which struggle for life amid the gloom of some old churchyards there. Lastly, it should be noted that in the family Lipariidæ we have this peculiarity, that the pupa or chrysalis is hairy as well as the caterpillar.—J. R. S. C.

SILVER VARIEGATED DECIDUOUS TREES.

THE golden and scarlet variegation among trees is justly admired and eagerly sought by connoisseurs. Of equal beauty, although of softer brilliancy, is the silver variegation. The silver-frosted vase has its own charms, even in contact with that which is golden-chased. Among these silver trees the following are worthy of notice:—

Variegated Ash-leaved Maple (*Acer Negundo variegatum*) is well known, and has a pure white variegation, covering half the leaf. Its effect upon a lawn is particularly fine, and it is highly valued in England and one or two localities in this country. It suffers fatal injury from our summer suns, and is not much used here except as a pot plant.

Variegated Ash is a very beautiful variety, not yet known in Europe, but recently sent to Flushing from Japan by Thomas Hogg. Its white is well defined and pure, covering nearly half the leaf and fairly rivaling the preceding in its beauty. It will be a very valuable addition to this class of trees.

Another variegated Ash from Japan is a new and curious variety, with its irregular blotching of silver or gold. Being of dwarf habit, it would find a striking position in front of a mass of dark-foliaged shrubs.

Variegated Japan Dogwood (*Cornus brachybotrya variegata*) was also sent from Japan by Thomas Hogg, and promises to be the most striking and valuable of the silver variegations. Its hardiness has been thoroughly proved in this country, both in winter and summer. The white, or light yellow, is clear, pure, and well defined, covering half the leaf, and a group of it on a lawn would be a striking object. It is very difficult to propagate, and must remain rare some time.

Another variegated Dogwood is the *Cornus mascula variegata*, which runs from silver to gold, but of a decided and permanent colour. It is a tree of moderate growth, scarcely above the largest of the shrubs. Its fruit, like that of the common variety, is esteemed by many. It formed a pleasant addition to my daily dessert when spending a few months in Lausanne, Switzerland, in the markets of which it was regularly offered for sale.

Silver-edged Oak (*Quercus pedunculata variegata*) is a very beautiful variety, clearly and permanently marked with a well-defined margin of white, which the hottest sun does not affect.

Spotted Oak (*Quercus pedunculata punctata*) is spotted with white points, and is somewhat changeable in colour.

White-and-green Oak (*Quercus pedunculata albo-viridi*) is irregularly blotched with white, changing more or less into gold.

Variegated Cherry (*Cerasus Mahaleb variegata*) has downy glaucous shoots, ovate glaucous leaves, and a white margin. It is a striking variety.

Silver Medlar (*Mespilus argentea variegata*). The leaves have a faint pink tinge, with a silver-marbled variegation.

Mottled Elm (*Ulmus campestris punctata variegata*). A mottled variety, with broad blotches of silvery white following the nerves.

White-edged Elm (*Ulmus montana albo-marginata*). Deeply silver-variegated towards the top and margins, with reddish leaf stems.

Japanese Silver-leaved Maple (*Acer polymorphum albo-variegatum*). A variety with deeply cut leaves, variegated with white, yellow, and green, and apparently of very recent introduction.

The preceding are a few of the best variegated trees, and are all perfectly hardy against our coldest winters.—S. B. PARSONS (in *Rural New Yorker*).

NOTES ON VILLA AND SUBURBAN GARDENING.

NOW that flower gardens are at their brightest and the various colours are clearly defined it is the time to make notes of proposed alterations, to prepare plans, and to renew fresh stocks in accordance with the requirements for another season's supply; therefore push forward the propagation of all kinds of bedding plants as rapidly as possible. Cuttings of almost everything invariably strike more readily and have time to become sturdy and well hardened-off if inserted now than when inserted later in the season. The considerable improvements made in carpet bedding during the last three or four years have caused a very noticeable falling-off in both the Gold and Silver-variegated sections of Geraniums, nevertheless they are still preferred by many amateur growers who do not possess the convenience of keeping the more tender subjects so necessary for the arrangements of carpet beds during the long winter months; whereas Geraniums are kept alive with a modicum of trouble, requiring just merely heat enough to prevent damp and to exclude frost.

The present season around London has been very favourable to the growth of our various bedding Geraniums, and the plants are now just in the prime for yielding cuttings. These should be tolerably hard and firm, as gross watery shoots are liable to damp-off. But in selecting cuttings the beauty and immediate effect of the beds must not be destroyed; a judicious thinning in the case of Geraniums is the best, and let this be done so evenly and regularly that anyone not seeing the operation performed could not tell from whence a cutting was removed. We generally go over the sorts required and take the cuttings off with a sharp knife, and place them in a basket and take them to the potting-shed, where the base of each shoot is cut clean across and the bottom leaves are removed; in the case of very strong cuttings of Geraniums the leaves are further

removed halfway up each cutting. When the whole of one sort required are made they are placed for awhile in the sun in order that the cut may become dried of its sap; this causes them to heal and emit roots the sooner.

The modes of striking bedding plants and stowing them away for the winter are many, each plan having certain advantages. One of the oldest plans, and still perhaps one of the best for amateurs if there is plenty of room, is to strike the cuttings in an open and well-prepared piece of ground, and when well rooted (which is generally about six weeks after the cuttings are inserted) to pot them singly in small pots, and place them on shelves near the glass to remain throughout the winter. This is a very safe way and one which we can highly recommend. Where a very large number are required pots are often dispensed with, but a quantity of roughly-made boxes are in readiness all of one uniform size, the sizes varying according to taste; but we have had them made 2 feet long, 10 inches wide, and about 6 inches deep. In preparing these boxes to receive the cuttings place about an inch deep of rubble over the bottom of each box, then the roughest of the soil, filling in the remainder with fine soil, and placing a layer of sand over the surface. The cuttings are then inserted, each box containing about sixty. A good watering is then given to the boxes, which are placed in an open position out of doors, where they are left to remain until there are signs of much wet or frosty nights, when they must be removed to their winter quarters. Where a large quantity of Geraniums are required this undoubtedly is one of the best means of storing away large numbers in a limited space; and temporary stages under Vines and other places have oftentimes to be utilised to hold them. There is another useful method adopted—that is, inserting four or five cuttings in 60-sized pots, and allowing them to remain in these pots until February before potting them off. The same remark applies to cuttings placed in boxes; they will require potting-off about February, in order to attain full-sized plants for planting at bedding-out time. Commence propagating the choicest Tricolor and other variegated Geraniums first, as these take the longest to root, following with the other sorts; then with Verbenas, Coleuses, Alternantheras, and such-like subjects, finishing off with the more hardy Calceolarias. The following sorts are among the best Geraniums:—Bedding Golden Tricolors: Mrs. Pollock, Sophia Dumaresque, Lady Cullum, and Sir Robert Napier; Golden Bronze: Beauty of Calderdale, Perilla, Bronze Queen, and Mrs. John Lee; and of the plain Yellow section Crystal Palace Gem and Robert Fish; White-edged varieties: Queen of Queens, Flower of Spring, Bijou, and Little Trot; and of the bedding Noddy and Zonal sections: Vesuvius, Star of Fire, Waltham Seedling, Wellington, Warrior, Lady Kirkland, Lucius, Rose Bradwardine, Bonfire, H. M. Stanley; and Master Christine, the old Christine, and Amaranth among the Pinks. Madame Vaucher and White Clipper are the best white-blooming varieties.

Verbenas are not so extensively grown now as some few years since, still they are associated with the memories of past-gone days, and are cherished accordingly. They are best struck in seed pans or pots of 6 or 8 inches in diameter, giving plenty of drainage, and filling the pot with some light soil in which a large proportion of leaf soil and silver sand have been incorporated. Take off short-jointed growths and insert them thickly all over the pots, water them to settle the soil, and keep close and shaded for a few days, when air can be admitted. These will not require potting or pricking-off as in the case of Geraniums, but will remain in these store pots, and furnish numerous cuttings, which will strike most readily in the spring and make healthy plants. Petunias may be treated in exactly the same way. Both the double and single varieties are old associates and bloom very freely; the double variety Mrs. Wilson is one of the best for beds. The clippings or trimmings of numerous kinds can be all utilised as cuttings instead of being thrown to the rubbish heap.—J. W. MOORMAN.

DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

HARDY FRUIT GARDEN.

THE time has again arrived when it is necessary to gather the crops of hardy fruits and to store them away for future use. It is well to have the tables and spaces in the fruit room thoroughly scrubbed. The walls ought also to be lime-washed, to make all sweet and cause a healthy atmosphere. Everything ought to be quite dry before the fruit is taken into the house. Some persons gather the fruit before it is ripe; but this is quite a mistake, as it neither keeps well nor is it of good flavour when gathered thus. The experienced cultivator can tell by the appearance of the fruit whether it is ready to gather or not; but a good test is to cut one (not the ripest), and if the pips are brown the fruit may safely be gathered. The more choice Apples may have the crops gathered at twice, or even a third gathering may be made. In the case of Pears this is quite necessary, as otherwise the crop would not last nearly so long. The dry weather is seriously affecting the quality and weight of the crop. It may seem

scarcely possible to our northern friends who are having so much rain and complaining of the want of sun when we make this statement; but so it is. As we write this there are threatening clouds gathering in the west, but most of the farmers would rather that it did not rain for at least two weeks, as they are in the midst of the Wheat harvest. The same circumstance that is checking the growth of our fruit has encouraged clouds of aphids to settle upon the Plum trees, where they have increased to an alarming extent. We never saw this pest attack the Privet before, but the hedge is quite smothered with it. There seem to be several species of aphids. Those that attack fruit trees differ considerably from the green fly of our soft-wooded greenhouse plants, and also of the Auricula and Carnation. Our Auriculas are quite close to Morello Cherries, and although the aphids from the latter frequently drop upon the plants, they wander about but do not settle to extract any nutriment from the leaves. Syringing the trees with a solution of soft soap and a little tobacco liquor added to it is the best way to clear the trees of the insects.

As opportunity offers we are cutting the young wood away from all the trees in the garden where it is not required for a crop next season. The method of doing this has been described in previous numbers, both as regards wall fruit and that on the open borders. Much of the fruit is attacked with the Apple-boring maggot. It does most damage to the Apples, but Pears and Plums suffer to a considerable extent from it. The fruit ripens prematurely and drops from the trees. On examining any of the specimens a small hole may be observed, and if this is traced the maggot may be found, and most frequently at the core. It is a wise plan to gather all the fruit that is attacked and have it destroyed. Strawberry plants recently put out are making rapid growth, but it has been necessary to keep the plants well supplied with water. Considering that Raspberry bushes like a deep moist soil the growth has been very satisfactory, owing possibly to the continued wet weather when the young growths started.

PINES.

As long as the nights continue warm and the sunlight is sufficient we will not apply artificial heat. Much can be done in this way by careful and patient attention to ventilation, especially at closing time, and this ought to be as early as possible in the afternoon. Either immediately before or after shutting up the house should be damped, and if this is done sufficiently the moisture will gather thickly upon the glass, which to a considerable extent prevents the sun from injuring the plants. If the plants intended to fruit next year are not yet potted into their fruiting pots no time ought to be lost in potting them. Complaints have been made this year about the plants not throwing up their fruit when expected to do so, but instead starting into a second growth. This is most likely to happen if the pots are not quite filled with roots before the plants are put to rest, and much also depends upon the manner of starting them and also the time. We have given the different details of this work at the proper time; at present our work is to see that the plants are well matured by being thoroughly exposed to the sun, and as much ventilation as possible must be insisted upon. The temperature of the house ought not to be less than 65° at night (of course it is as high as that now without artificial heat); by day 10° to 15° higher than this is desirable, but during hot days the thermometer may range even 20° higher, and that with plenty of ventilation. Those that will be started about Christmas should now be very near their resting period.

CUCUMBERS AND MELONS.

It is now a good time to sow seeds to produce plants for bearing Cucumbers at Christmas. The plants ought not to be allowed to come early into bearing, nor ought they to produce much fruit if it is intended that they are to bear well from Christmas onwards. Munro's Duke of Edinburgh is one of the very best for bearing at that time in the estimation of some, others still hold to Telegraph as being the best; with a true stock of Telegraph there will not be much danger of failure. We fancy that the half-span house is as good as any other for growing winter Cucumbers, others prefer a lean-to. Whichever form is adopted, a main consideration is to have plenty of hot-water pipes, so that the temperature during a severe frost may be kept up to 65° without overheating the pipes. As the plants progress in growth they must be trained, and the shoots should be stopped frequently in order to obtain a uniform stocky growth all over the trelliswork. This ought to be about 10 inches from the glass in the winter. When the plants are young and producing their first leaves these are usually of large size, and when they overshadow the young growths it is usually better to remove them altogether. Melons ripening should have the ventilators open night and day, and not much moisture to be permitted in the house. Cut the fruit and remove it to the fruit-room as soon as it begins to crack where the stem is attached to it.

GREENHOUSE AND CONSERVATORY.

We are not doing much in this department except attending to the plants which are in flower and removing any decaying

leaves and flowers. Those who have not yet grown Phloxes in pots for greenhouse decoration should do so. There is so much variety in the colour of the flowers; and the tall spikes of bloom, arranged so that they tower erect over other dwarf flowering or foliage plants, have a charming effect, and the flowers moreover are sweetly scented. The culture is so simple, too, that glass protectors in any form are not needed. It should be mentioned that our stage Pelargoniums are intended to flower rather late in the season, else the plants ought to have been cut down much earlier. We have now cut them down and the young growths are starting freely. A few specimens of the aphid tribe have been observed; the house will be fumigated with tobacco smoke until all traces of them are removed. We are also moving other greenhouse plants into the house, in each case seeing that no insect pests or mildew are allowed upon any of them. A few of the younger specimens have quite filled the pots with roots; and although it is so late in the season we shall repot them, as the weather is very favourable indeed for this purpose. Probably most of them will be repotted before this appears in print. Climbing plants trained to the roof must be well thinned out, as the leaves shade the plants too much, especially at this season of the year.

FLORIST FLOWERS.

We have now inserted more pipings of Pinks in shallow boxes and placed the boxes in a shady place, just placing some squares of glass over them to retain a moist atmosphere. They strike best and quickest with a little bottom heat, but we are trying them without it. The first lot of pipings rooted much better than we expected, and there is now a goodly number of fine plants. Some few of them, such as James Hogg and Dr. Masters, are not easily managed, but with care we have never lost any variety after it has become established.

Auriculas never looked so healthy as they are doing now, and they are making very good growths. The plants have been carefully looked over, and all decaying leaves removed with the offsets. These last have been much more numerous than usual. Some sorts, such as George Lightbody (Headly) have produced as many as six offsets from one strong plant. We would rather that they had not run so much to producing young stock, as the main stem is considerably weakened thereby. One or two of the best old sorts have still baffled all our skill to make them grow vigorously. Freedom (Booth) is one of the most difficult to manage, but still we will not despair of achieving the same success as Mr. Horner has done. He was years before he could get vigorous development into his plants; now the leaves are large and of a healthy dark green colour. Page's Champion seems to be, as the Scotch would say, a very "dirty" variety, and the leaves have a tendency to curl. A plant of any sort if it is in good health ought to have the leaves spread out, thick, and crisp. We have the plants fully exposed to the air night and day; the lights are placed over them merely to throw off the rains. The offsets have been potted in small pots in light soil, and the pots are placed in handlights, where they are kept close except on still calm days, when the lights are removed.

We have just finished layering the Carnations. We could not do them sooner, because the flowers were still fresh on many of the plants; indeed, we had to cut several dozens of flowers on the 17th in order that the layering might be done. Considering that a good stand of flowers could have been cut on the first week of July, and that a hundred blooms could have been cut any day for a period of about six weeks, no one can say that the flowers of Carnations are of a fugacious character. After layering the plants are placed in an exposed position out of doors. —J. DOUGLAS.

TRADE CATALOGUE RECEIVED.

Dickson, Brown, & Tait, 43 and 45, Corporation Street, Manchester.—*Autumn Catalogue of Dutch and French Flowering Bulbs.*

TO CORRESPONDENTS.

* * All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

SEEDLING GLOXINIAS (S. H. K.).—There is no novelty in your seedling Gloxinias, and there are much better strains already in cultivation.

ROSES (Gorilla).—We have no communication from you.

POTATOES DISEASED (E. Stanley).—The tuber you have sent is affected by dry gangrene. Change of seed and change of soil are needed.

STREWING RUSHES AND FLOWERS (H. W. S.).—The custom at your village festivals and ceremonies is a remnant of an old and excellent mode of complimenting. Thus some lands at Aylesbury were held by the service of, amongst other things, finding "*herbam ad juncandam cameram* [Regis]"—that is, "grass or hay to strew after the manner of rushes in the King's chamber."—(Blount, *Frag. Antiq.* 181.) Hentzner notices that Elizabeth's presence-chamber at Greenwich was strewn with hay. Shakespeare introduces a groom strewing rushes at the coronation of Henry V. The stage was commonly strewn with rushes.—(Collier's *Annals*, iii. 364.) Occasionally the strewing was of a more costly character. The bride used "to walk to church on flowers," and the strewing of flowers is even yet used at our coronations. This subject is treated in Brand's "*Popul. Antiq.*" vol. ii. p. 48, and Nares's "*Gloss.*" p. 440. Several illustrative passages from Shakespeare have been there noticed, but not the following:—Grumio inquires, "Is the supper ready, the house trimmed, rushes strewed?"—(*Taming of the Shrew*, iv. 1.) And Romeo at the masked ball exclaims—

"Let wantons light of heart

Tickle the senseless rushes with their heels."—*Romeo and Juliet*, i. v.

These, it will be observed, are both instances of the use of rushes in private houses upon occasions of more than ordinary ceremony.

GRAPES CRACKING (A Constant Reader).—As you cannot diminish the supply of moisture to the roots of the Vine you can only check the supply of sap to the Grapes by cutting half through the spurs just below the bunches, and removing some of the leaves above them.

COTTAGE GARDENERS' DICTIONARY (—).—It has not been revised for nine years. Apply to the publishers for information.

ARTIFICIAL MANURES (G. C. E.).—Small quantities may be purchased of Mr. S. Hawley, Manure Merchant, Suffolk Street, Forest Gate, Essex.

DESSERT APPLES (J. E.).—To succeed the Ribston Pippin you may cultivate Cox's Orange Pippin, Court of Wick, and Court Pendu Plat. In our "Garden Manual" you will find information about Roses.

CLIPPING YEW (A Constant Reader).—You may clip it now, but many prefer clipping early in spring.

MELONS UNHEALTHY (R. A. P.).—The Melons we think have been over-cropped, and also over-excited. The foliage is large and thin in texture, suggestive that the house has been too hot, and especially too close. Probably had the temperature and ventilation been correct the plants would have been sufficiently robust to have carried the crop, which is now too heavy for them. The leaves are also infested with red spider. The night temperature should be about 60°—not below, nor many degrees above that figure—with just a chink of ventilation at the top of the house all night. The plants should be freely syringed during the afternoons of clear days, except when the fruit is setting or ripening, closing the house at a temperature of 85° or 90°. Air must be admitted very early in the morning—as soon as the thermometer commences rising, increasing the ventilation gradually as the heat of the house increases to its maximum of 85°. During sunny days keep the paths of the house moist, letting it become fairly dry, however, once a day for a short time. Employ as little fire heat as possible, but take full advantage of sun heat by closing the house early in the afternoon.

STORING POTATOES (A Reader).—We strongly advise you to keep the tubers spread thinly in a cool dry place, at least for a considerable time to come. They should not have too much light or they will turn green. If you must "clamp" them let them be perfectly dry first, and keep them dry and as cool as possible.

STRAWBERRIES (Idem).—Three useful sorts, in addition to those you have are President, Sir Joseph Paxton, and Frogmore Late Pine. They will thrive in any good soil. You will not err by ordering from one of the nurserymen advertising in our columns. We cannot break the rule to which you refer.

SCALE ON FERNS (S. H.).—We think the fond set is one of *Asplenium bulbiferum*, but the specimen is very imperfect. As you have not time to sponge the fronds and Myrtle foliage we advise you to dissolve 3 ozs. of soft soap in a gallon of water, and syringe the infested plants with the solution at a temperature of 120°. Lay the plants on their sides on a mat, so that the warm soapy water does not saturate the soil. Repeat the syringing at weekly intervals.

TIGER LILIES (J. W. S.).—The little embryo bulbs on the stems of *Lilium tigrinum* may, as soon as they are ripe and come off freely, be planted 4 inches apart in rather light soil which is not likely to get water-logged in winter, and they will form flowering bulbs in two or three years.

CHERRY TREES UNFERTILE (G. H. P.).—Without knowing the nature of your soil we cannot be certain as to the cause of your Cherry trees growing luxuriantly without perfecting fruit, but a soil too rich in vegetable matter and deficient of lime would produce like results. Try the effect of a dressing of bone manure, or even common lime. Your *Yucca recurva* is very fine, and favours the idea that your soil is too rich for stone fruits. They would be likely to make more growth than they could mature, and although they produce blossom freely and beautifully it may be imperfect in some respect, and consequently cannot produce perfect fruit. If you are sure the failure is not caused by a deficiency of lime try the effect of root-pruning, which may be done at once.

GERANIUMS FOR WINTER FLOWERING (Fly).—Cuttings of the Zonal section struck in the spring, and the plants potted-on as they increase in growth, are the best for winter flowering. The trusses of bloom should be removed during the summer and autumn months, the plants must be placed near the glass, and the temperature of the house be about 56°. Nearly all the varieties flower freely. They do not flower so well in large pots; 6 and 7-inch are sufficiently large, and no manure should be mixed with the potting material. The early-flowered section of Stage Pelargoniums are very useful for succession, such varieties as *Triomphe de St. Maude*, *Duchess of Edinburgh*, and the more recently introduced *Duchess of Bedford*.

TRIPS ON VINES (E. N.).—It was stated a few weeks ago in "Doings of the Last Week" how this pest was destroyed. We would certainly fumigate on three nights, at intervals of three days. Very probably the insects would not all be destroyed after that. The wood of both Vines and Peach trees ought to be washed in the winter after removing all loose bark from the old wood.

GESNERA CULTURE (J. A. Croydon).—You do not say what is the species or variety; we presume it is *G. zebrina splendens* or *G. exoniensis*, both fine winter-flowering plants. They succeed admirably in a stove having a winter temperature of 60°, falling to 55° at night; and 65° by day with a rise of 10° or more from sun heat. Ours are kept in the stove constantly, and when the

plants have ceased flowering they are not watered except to prevent the foliage flagging, and when that decays it is removed, no water being given, but the pots receive some moisture consequent upon sprinkling the house two or three times a-day. Shortly after the foliage decays the tubers are carefully removed from the soil. The pots are cleaned inside and out, drained a fourth of their depth, an inch of the rough of the compost is placed over the drainage, and they are filled to within an inch of the rim with compost, consisting of two parts of light fibrous loam, one part each of leaf soil or old dry cow dung and sandy peat, with a half part of silver sand, the whole broken up fine and well mixed. The bulbs are placed about 3 inches apart all around the sides of the pots, and so that the growing end is about an inch therefrom, and covered an inch deep. Only the largest tubers are used. No water is given. They are placed in the stove. The soil is kept more or less moist through syringing, but no water from the pot is given until the plants are an inch above the surface, then it is given in moderate quantity, avoiding making the soil sodden. The plants when growing are sprinkled overhead twice daily, and slightly shaded from bright sun in summer. A suitable summer temperature is 65° at night from fire heat, 70° to 75° by day, up to 85° or 90° with sun. When the flower heads show weak liquid manure is given once a-week. The plants with us commence flowering in November or December, and are often fine until February.

PLANTING ONIONS FOR SEED (A. B. G.).—Select the largest and best-formed bulbs, and plant them in February in an open situation, but if possible sheltered from wind. Drills may be drawn 3 or 4 inches deep, planting so that the crown is just covered with soil; or the bulbs may be planted with a blunt-ended dibble. The rows should be 1 foot apart and the bulbs 6 inches asunder, leaving a path 2 feet wide between every four rows. Keep clear of weeds, and when in flower stakes should be driven in, and tarred cords stretched horizontally on each side of the row of stems a few inches below the heads, to serve as a support and prevent their being broken down. In August the seed will be ripe, which is intimated by the husks becoming brownish; the stalks should be cut off near the ground, laid on a cloth in the open air for a few days to dry, but during that time they must not be exposed to rain. When dry the seeds may be rubbed out, cleaned of the chaff, and stored.

SOWING BROAD BEANS FOR SEED (Idem).—The seed should be sown the end of February or beginning of March. Early Mazagan and Longpods may be sown in November, but all the sorts will ripen seed perfectly if sown at the time named.

GRAPES NOT COLOURING (H. O.).—As your Vines are old and have only small bunches we should attribute the deficiency of colour to weakness, which may probably be remedied by allowing more foliage—lateral growth, especially so as to maintain active root-action until the fruit is perfectly ripened. The flower was too much smashed for identification.

RASPBERRIES (Subscriber).—Carter's Prolific and Fastolf are good red sorts. Those and the Sweet Yellow Antwerp will be likely to suit you.

SEEDLING GLOXINIA (H. L.).—The flower sent is very good. It is of great substance, and the colours—exterior of the tubes very pale rose, with crimson lobes edged with pinkish white—contrast effectively. Messrs. Veitch, however, frequently exhibit flowers of equally good quality.

LILIES DYING FROM WIREWORM (D. C.).—Place slices of carrot on sticks and bury them a few inches underground, examine them daily and destroy the wireworms found attached to them. If the ground is damp you must drain it.

LIST OF ROSES (Idem).—"Real" pink, Duchess of Edinburgh (Bennett), Lyonnaise, and Mdle. Thérèse Levet; dark red, Alfred Colomb, Maréchal Vaillant, and Sénateur Vaisse; good pink for forcing, Princess Beatrice, Duchess of Edinburgh, and Lyonnaise, or La France may be substituted, but it is a pale peach colour.

BOILER (Winter Garden).—No one could recommend any one confidently without seeing the places to be heated. Consult some gardener who has houses like your own.

INSECTS (Lancashire Old Subscriber).—They are familiarly called "Ruby-tailed Flies" of the family Chalcididae, the species being, we think, *C. ignita*. Though designated "flies" they are in the order Hymenoptera, and are parasitic in habit, the larvae being deposited in the nests of solitary bees and wasps. The abdomen is furnished with a peculiar ovipositor, which is also stated to have the power of stinging. In the garden it is neither injurious nor beneficial. (*J. H.*)—Those accused of attacking the Gladioli are not properly insects, but a species of *Julus* or *Millipede*. Like others of that family it is difficult to deal with. We know of no better remedy than careful hand-picking. The hardness of the integuments probably would defy the effects of a solution of ammonia, which is often found so successful in the case of worms and other subterranean feeders. Guano round the bulbs might banish the vermin.

NAME OF FRUIT (Connaught Subscriber).—Your Plum is *Belle de Louvain*.

NAMES OF PLANTS (Three-years Subscriber).—*Hoya bella*. (*W. W. A.*)—Apparently *Dendrobium transparens*, but material very scanty. (*A. C. R.*)—1, *Spectamen* insufficient; 2, *Rhus cotinus*; 3, *Spiraea opulifolia*. (*J. G.*)—1 and 2, *Lactea Filix-mas*; 3, *Polypodium vulgare*; 4, *Spiraea salicifolia*. (*F. T. F.*) *Lucern* (*Medicago sativa*). (*Constant Reader*)—1, *Liatris spicata*; 2, *Achillea ptarmica*; 3, *Antennaria margaritacea*; 4, *Catananche cerulea*. (*D. G. R.*)—1, *Panicum dysenterica*; 2, *Butomus umbellatus*; 3, *Ranunculus Flammula*; 4, *Sorophularia nodosa*; 5, *Lysimachia ciliata*; 6, *Senecio aquaticus*. You should get some book on British plants. (*R. P.*)—1, *Pteris serrulata*; 2, *Nothochloa distans*; 3, *Laetia Filix-mas*, crested variety; 4, *Adiantum hispidulum*; 5, *Pellaea hastata*; 6, 7, *Pteris tremula*; 8, *Asplenium trichomanes*. (*Constant Reader*)—*Adiantum formosum*; 2, *Pteris incisa*; 3, *Aspidium coriaceum*. (*Lady C. Turnour*)—1, *Aspidium acrostichoides*; 2, *Nephrodium marginale*; 3, *N. noveboracense*; 4, *N. dilatatum* var. *intermedium*.

POULTRY, BEE, AND PIGEON CHRONICLE.

COTTAGERS' POULTRY SHOWS.

THERE are in many districts in the present day local cottage-garden shows, and there is hardly a village that has not some annual gala—a fair, a club, or a friendly society's meeting. We

should like to see attached to some such annual festivity, of whatever kind it may be, some classes for table poultry, Ducks, and Rabbits belonging to cottagers only. Where possible, such classes would be best if they could be added to a cottage-garden show, so that at one time the various exhibits from the cottages of the district could be on view. We have long thought such little shows confined to some certain number of villages would prove of much value and interest. We believe they would tend to excite our humbler friends to cultivate poultry, which we never believe our present system of poultry exhibitions will do; in fact, the shows of prize fowls which are now weekly taking place do not in the remotest degree help to increase the cultivation of poultry as food. There may be isolated cases to the contrary, but the breeders of prize poultry for exhibition do not, we believe, think of their fowls in any way as articles of food, and the cottagers who have not the means, or opportunities, of breeding very high-class stock are consequently quite debarred from the pleasure and usefulness of exhibiting. We know of several villages where the cottagers keep three or four hens each, and by the sale of their eggs and the produce of a brood or two of chickens are enabled to have many little extra comforts which they would otherwise have to go without. Again, we know of some villages where a brook or stream of water runs through the place. The cottagers here keep two or three Ducks and obtain good prices for their ducklings. Such people want encouragement, and what one village can do many more can also perform. Poultry fit for the table will always command a remunerative price, and chickens and ducklings in all localities will always find a ready sale, while eggs are frequently sought for through the autumn and winter months in vain. We should all try to help the small incomes of a labourer's family in an honest way, and we verily believe some classes for their poultry and Ducks tacked on to the district cottagers' show if there is one, or held in some neighbouring barn or shed at the time of the annual village festival, would soon effect much good.

For the classification of such a little meeting we would have the simplest titles. We would have no particular breeds: we should recommend that the classes should be something like the following—(1) for the whitest skinned and legged pair of chickens; (2) for the heaviest pair of ditto; (3) for the most useful-looking cock and hen; (4) for the ditto drake and Duck; (5) for the heaviest pair of ducklings; (6) for the largest buck or doe Rabbit; (7) for the heaviest pair of young Rabbits; (8) for the heaviest dozen of single-yolked eggs.

One, two, three, or more prizes could be offered in each class, and other similar classes could be added at pleasure. Such classification would surely place all cottagers on the same footing, and would make them keep a large and useful breed of fowls, which would give them so much the more chance of a prize. The prizes need not be large; a 5s. first prize, 3s. second ditto, and 1s. third would answer most purposes, and the honour of the prize and the better sale of chickens which would consequently be obtained would have nearly as much effect as the money prize itself. We would have no classes whatever for Bantams or fancy breeds, for though they may be very interesting to some home circles and be made great pets of, they have nothing to do with our present object—viz., of encouraging cottagers to keep poultry for profit and to increase the supply of wholesome food.

We have had to do with two such little meetings this summer. The one we judged, and for the other we acted as honorary secretary, and we do not hesitate to say for first shows the success and the interest taken in them fairly surprised us. Excellent white-legged chickens were on view, well-grown ducklings, and large Rabbits; but perhaps the most satisfactory part of all was to hear the cottagers' remarks and to note their earnest attention to what the Judge in future required, such as white skins and straight breasts, and, where possible, uniformity of colour in a pair of birds. Repeatedly we heard one remark to the other that they should try another year, for what the next-door neighbour achieved they concluded they could also perform.

We have seen in some schedules a class "for cottagers only;" but such are really quite useless, for the schedules never fall into the hands of the desired people, and, if they did by any chance, such would not have the money to risk in entrance fees and carriage, or have proper baskets to send their birds in by rail. Neither do we think that a class for "cross-bred table fowls" is of the slightest use, for exhibitors in general do not care to have to do with such classes, and farmers but very rarely hear of them. We trust that those who have the interest of their villagers at heart will try to establish some such system and give the shows a fair trial of two or three years, for we venture to think a most unlocked-for result will crown their efforts. We do not speak so much of the northern counties, for many villages in Lancashire and Yorkshire have an annual show on a much larger scale, where the people would laugh at the simple classes which we propose; but in the southern and western counties we believe there is a good opening, and that there are scores of

villages which would eagerly support a cottagers' poultry show.—W.

DURHAM COUNTY POULTRY, &c., SHOW.

THE annual Show was held at West Hartlepool on the 17th inst. The entries were not large, the prizes offered not being such as to induce great entries, although the birds were pretty well divided. First on the list were *Dorkings*, and the winners were very good Dark Greys, and the *Cochins* unusually good. In *Polish* first were very fine Black Polish, the remainder being Golden. *Game* were very good but not numerous. *Hamburghs* were good in all classes, but the best pen of this variety was in the chicken class, the second to them being good Buff *Cochins*, and third White *Dorkings*. In *Game Bantams* first were a pen of Piles good in every respect, and second and third Black Reds. In *Bantams* any other, first and second Blacks, and third Silver Seabrights. *Ducks* were uncommonly good in both classes, the *Aylesburys* especially fine.

Pigeons were poor, except in the Turbits, Jacobins, and Owls. *Rabbits*, Lop-eared, first a Fawn and second a Tortoiseshell. *Angoras*, only winners good, and Himalayans moderate, as they were very much faded on the feet. In the Variety class first was a Silver-Grey, and second a Grey-and-white Dutch.

POULTRY.—*DORKINGS*.—1, J. White. 2, M. S. Buxton. 3, W. Morrison. *COCHINS*.—1, 2, and 3, G. H. Procter. *SPANISH*.—1, E. Nicholson. 2, T. Newlands. *BAHAMA POULTRY*.—1, Miss Cotes. 2, J. Hardy. *POLANDS*.—1 and 3, J. T. Proud. 2, J. Garrett. *GAME*.—1, J. A. Nelson. 2, G. Alderson. 3, J. Hamilton. *HAMBURGHS*.—*Golden-spangled*.—1, R. Keenleyside. 2, G. Grainger. *Silver-spangled*.—1, G. Alderson. 2, Maude & Scott. 3, G. Grainger. *Golden-pencilled*.—1, G. Alderson. 2, J. P. Carver. *Silver-pencilled*.—1, D. Clow. 2 and 3, G. Alderson. *BANTAMS*.—*Game*.—1 and 3, J. A. Nelson. 2, F. S. Hookaday. *Except Game*.—1 and 3, G. Alderson. 2, J. Muir. **ANY OTHER VARIETY**.—1, R. Hawkins. 2, G. Alderson. 3, J. P. Carver. **ANY BREED**.—*Chickens*.—1, G. Alderson. 2, G. H. Procter. 3, H. Cockton. *Ducks*.—*Rouen*.—1, F. E. Gibson. 2, J. A. Nelson. 3 and *who*, Miss Robinson. *Aylesbury*.—1, 2, and 3, F. E. Gibson. *who*, W. Porter.

PIGEONS.—*CARRIERS*.—1, J. L. Nicholson. 2, C. F. Cockhill. *TUMBLERS*.—*Almond*.—1 and 2, G. Alderson. *Any other variety*.—1 and 2, J. Davidson. *FAN-TAILS*.—1, P. Wilson. 2, G. Alderson. *TRUMPETERS*.—1, G. Alderson. 2, Maude and Scott. *BARRS*.—1, G. Alderson. 2, E. Nicholson. *JACOBINS*.—1 and 2, G. Alderson. *who*, J. Davidson. *TURBITS*.—1 and 2, G. Alderson. *who*, Maude and Scott. *OWLS*.—1 and 2, G. Alderson. *POTTERS*.—1, P. Wilson. 2, G. Alderson.

RABBITS.—*LONG-EARED*.—1, J. S. Robinson. 2, G. H. Young. *ANGORAS*.—1, A. Richley. 2, J. S. Robinson. *HIMALAYANS*.—1 and 2, M. Fletcher. **ANY OTHER VARIETY**.—1, J. W. & O. Moses.

JUDGE.—Mr. E. Hutton.

PIGEON NOTES.

No creature is so thoroughly helpless as an infant Pigeon; but this is a wise dispensation of Providence, for the young squab is less likely than more precocious birds to get into danger during the absence of its parents in search of food for themselves and young. They have just instinct enough to hold up their heads and feel the bills of their parents, who at first feed them in a curious manner with a soft curdy secretion, which is produced in their crops at the end of the period of sitting. This secretion of soft food, says Mr. Tegetmeier, cannot be delayed; consequently if the young birds do not emerge from the egg on the eighteenth day, the old birds desert the nest, refusing to sit longer. The production of the soft food, however, may be hastened a day or two. If a pair of chipped or hatching eggs be placed under a pair of birds that have been sitting sixteen days, their presence will always stimulate the secretion of the soft food, and the young will be duly nourished.

The formation of this curdy secretion—true Pigeon's milk—is a very remarkable fact. It seems determined altogether by the process of sitting; it is produced equally in both parents, though the hen sits about twenty hours and the cock only four. To receive this nourishment, the young thrusts its beak into the side of the mouth of the old bird, in such a position that the soft food which is disgorged from the crop of the parent with a sort of convulsive shudder, is received into the lower mandible or jaw, which is widely extended in order to receive it. As the young advance in size the soft food lessens in quantity, and the grain and seeds that constitute the nourishment of the parents become mingled with it; and when about eight or ten days old the young are fed with disgorged grain and seeds only, until such time as they are able to fly and seek their own nourishment.

The proper time to kill Pigeons for the table is just before they leave the nest, when they are about a month old. As soon as they begin to feed themselves they begin to grow lean, and their flesh loses that tenderness and delicacy of flavour which belongs to young Pigeons.

Parasites.—Pigeons are subject to five unpleasant and troublesome insects, which will infest their houses and breed among their plumage unless the most scrupulous cleanliness is observed. A little snuff sprinkled over the birds and into their nests will give temporary relief, but the nuisance can only be thoroughly eradicated by burning the infested nests, lime-washing the inside of the loft, and washing the nesting places with limewash or tobacco water. These vermin are fleas, lice, feather lice, mites, and ticks. These parasites are a peculiar species, which do not fix themselves on the human skin. The fleas are

smaller and blacker than the common flea. They may be got rid of by brushing out the nests and corners, and prevented by not allowing dirt, dust, and feathers to accumulate.

Lice usually infest sick or delicate birds, breeding chiefly about the head and neck, but also running over the whole body, annoying the birds and keeping them from getting strong. Butter or lard rubbed on the skin is said to kill them, but a little powdered sulphur dusted in among the feathers is the best remedy. Cleanliness and keeping the Pigeons in good condition are the best preventives.

Feather lice are elongated and flattened in form, very tough, and difficult to remove from the feathers, between the fibres of the veins of which they frequently swarm. They do not seem to cause the bird any inconvenience; and as their food is the down at the quill end of the feathers, it seems almost as if they were intended to reduce the warmth of the bird's covering in summer, for their number must be very much decreased at moulting-time by the quantity cast off with the old feathers, and not until spring can they increase sufficiently to thin the warm under-covering of down, which in summer is not so necessary for the Pigeons as in the cold months of winter. Nevertheless, they are always decreased by attention to cleanliness; and as "cleanliness is next to godliness," and its necessity to health has been insisted on by the greatest physiologists, the theory cannot be maintained.

Mites are the smallest, most common, and troublesome of these pests; the largest are not larger than grains of poppy seed. They are generally black, with white streaks or spots on their bodies. They do not appear to live on the bodies of the Pigeons, but inhabit the chinks in the walls, the cracks in the wood, and dark corners of the nesting-places, and often congregate in thousands in the nests, whence they issue at night when the Pigeons have gone to rest, and feed till they are red, instead of being black and white. Squabs suffer more than the old birds with them. The mites get into the ears of the young birds and torment them much in warm weather, making them lean and miserable, and retarding their growth, often causing their death. A drop of oil in the ears, under the wings, and where else the mites may be seen, will prevent their annoying the young. Powdered sulphur strewn in the nests, and dusted among the feathers of the old birds, is the best plan I know of. As a preventive means, stop all cracks and chinks, let the wood-work be planed and painted, and do not give the Pigeons hay for nests; heath and birch twigs are the best. Washing the walls, painting the woodwork so as to stop all cracks however minute, and perhaps the addition of powdered sulphur in the limewash, may be a good precaution.

Ticks are the largest and most disgusting, and fortunately the most rare of these parasites. They generally infest the head and back of the bird, and grow as large as tares, when, the feathers not being sufficient to hide them, they may be picked off. Mr. Bent says they proceed from an ugly, curious flat-looking fly, about the size of the common house fly, of a slaty grey colour, and very flat in form. Cleanliness and flour of sulphur are the only remedies.

Diseases are generally the result of mismanagement, exposure, lack of ventilation, cleanliness, exercise, proper accommodations, or pure water for drinking and bathing. However, in such evils as falling of the gizzard or navel, and the like, that are indications of a weak constitution, the birds are better killed.—(*American Fanciers' Journal*.)

PREPARING STOCKS FOR WINTER.

ASAP from the heather the season for honey is over, and the sooner stocks are prepared for winter the better. The preparation of stocks in autumn is not the least important part of apiculture. Now is the time to lay a solid foundation for success another year. Young apiarians about to engage in this work will, I trust, permit me to give them three watchwords:—1st, Plenty of young bees; 2nd, Plenty of food for them; and 3rd, Warm and comfortable houses to live in.

Owing to unfavourable weather many of the late swarms have not filled their hives with combs, and have little or no honey in them. They are not worth taking for their honey. Are they worth keeping? As a few strong hives yield more profit than double their number of weak hives, it is often advisable to unite the bees of the weak to stronger hives, and thus make sure of having some excellent stocks. Every bee-keeper must decide for himself how many and what stocks he will keep for another year; but let me say that hives not full or strong now may be made stronger by artificial treatment. Vigorous and constant feeding at the present time would cause the bees to commence breeding afresh, and comb-building too where necessary. Thus weak and comparatively worthless hives may be fed into pretty good stocks before the end of September. Two hatches of six combs of brood would make a hive by that time strong in young bees. Part of the syrup given to promote breeding and comb-building would be stored up for winter food. Far more good will be accomplished by feeding now than by

doing it later in the season, so far as breeding and comb-building go. Bees are easily stimulated into active efforts during warm weather, whereas they are more difficult to move in the way of extension and expansion during the chilly weather of autumn; then they naturally abstain from comb-building and cluster closely together.

In breeding and comb-building there is necessarily a great consumption of food. Early and continuous feeding produces better stocks, and thereby necessitates a larger supply of food. Some of the larger supply goes for comb-building, some for brood, and some is needed for the increased population of the hives. What a stupid and strange mistake some writers on bees made in asserting that a small population in a hive needs as much food as a larger one! The readers of this journal know better. I know that 40,000 bees require twice as much food as 20,000. If a large swarm of 40,000 bees (about 8 lbs. in weight) be placed in an empty hive at the end of August it will require about 20 lbs. of sugar (40 lbs. of syrup) to make it safe for the winter. From the 40 lbs. of syrup the bees would fill or nearly fill their hive with combs and brood, and store-up food enough for themselves till the end of March. About one half (20 lbs.) of the syrup is used in comb-building and for brood and bees during the month of September. The other half is stored up for winter keep, and in ordinary seasons is enough for a very strong hive. Hives that are full of combs do not require so much syrup, and if hives have bees enough for winter continuous feeding should be avoided. The more rapidly such hives are fed the more food is stored up, because less is consumed in the excitement of feeding. The principal idea I am seeking to convey in this letter to youthful apirians is this—that syrup given regularly every night to healthy hives will cause the bees to recommence breeding, and thus replenish their hives with a numerous and valuable population. Feeding should be commenced as soon as possible, and be continued without halt till it is completed. Late feeding is attended with the danger of causing the bees to breed at an untimely season. Bees may be lost in going out for water, and brood may be chilled to death.

Our third watchword is a good warm house for bees to live in. It is much to the interests of the bee-master that his little industrious servants be well provided for, and be well protected during the winter months. Bees deserve comfortable houses with all proper sanitary arrangements, including proper and perfect ventilation, for the internal moisture of hives is often more hurtful to them than anything else either outside or inside. Many of my readers would be astonished, if they were to turn up their hives at the present time and examine their insides, what a hurtful mess of condensed moisture they would find on the inner surfaces of their hives. This discovery would perhaps lead to a second examination and the consideration of the importance of the ventilation of hives. In touching this subject on former occasions I have given offence to some parties, but my object is to enlighten public opinion and advance apirian science. Hives that let their internal moisture sift out and escape are far more comfortable and better for bees than those that keep it in. Many bee-keepers have this lesson yet to learn.

Hives of proper materials—indeed, hives of all kinds—require protection by covering from the storms of winter. Hives standing out of doors cannot be too warmly covered during the winter and early spring months. This lesson is easily learned, but more difficult to practise, especially where many hives have to be covered.—A. PETTIGREW.

FEEDING BEES.

I HAVE tried two ways of feeding—with barleysugar and syrup, sugar and water boiled to a proper consistence. The former I find very useful, putting the sticks on the top of the hive, as I find feeding at the top always best. Some time ago I found a quantity of fat left by the bees from the barleysugar, and it is a curious fact that they should be able to suck-out the saccharine matter and leave the fatty. To make the syrup I put oil sugar and water boiled to a proper consistence, fill a wide-mouth bottle, tie-down with muslin, and turn over and insert into the hole at the top of the hive. This I find a good plan when regular heavy feeding is required, but watching is necessary that the syrup may be renewed. I have never found it become candied, although some persons object to it on that account. But it would very soon be found out and remedied. Beer or vinegar may be added to it. I have never tried either.—R. B. R.

OUR LETTER BOX.

MARKING POULTRY.—"A. B." asks for a simple method of marking poultry so as to distinguish readily birds of one year from those of another year. There is the drawing of a ring for the purpose in our twenty-sixth volume, new series.

CONFINED SPACE FOR FOWLS (J. S. T.).—Cochin-Chinas or Houdans would endure the confined space much better than any variety of Dorking.

TAKEING HONEY (A Novice).—We advise you to drive the bees out of the

old straw hives and put them into empty bar-frame hives. Probably the hive that you have made is as good as any you can buy, but the "Italian frame hive" which you have purchased is not a proper hive for bees in this country. The people and country that produce and use such hives are not far advanced in the art of bee-keeping. Mr. Leo of Windesbam, Bagshot, and others about London can supply you with hives far superior to the Italian one. First drive the bees into straw hives or round boxes, then cast them into the bar-frames and place them where they now stand. Boil 30 lbs. of sugar in thirty pints of water, and give all the syrup to the two swarms in fourteen days—about 2 lbs. of syrup every night to each swarm. In this way you will get the honey from the old straw hives and two good stocks in frame hives. Do not attempt to fill the frames with old combs—a most foolish practice with some bee-keepers, for bees readily make fresh combs from syrup, and thrive and prosper amongst them exceedingly. If you want the honey from your large circular box the bees should be driven from it and hived in a bar-framer. Your three swarms in smaller boxes may remain as they are for stocks. You will have to venture sometime on the task of driving bees, and you may as well begin at once. All you want is a little courage and self-possession. As soon as the bees are driven from the combs see that the honey is run from them. Honey should be run before it cools.—A. P.

BEE PASTURAGE (G. C.).—The bees will obtain honey from the peppermint. They have been proved to visit flowers nine miles distant from their hive.

CREOSOTE.—"M. A. H." asks what are the proper proportions of creosote to mix with water to steep different kinds of woods in, and more especially prepared oak for waterwheels at a corn mill? Will water counteract the desired effect? and will creosote take the same effect on firs and pines as on all hard woods?

REMARKS.

15th.—Very thick morning, but soon clearing off, and the day beautifully fine; starlit night.

16th.—Fine pleasant day; cooler towards evening, and bright starlit night.

17th.—Another bright fine day.

18th.—Rather hazy in the morning, bright pleasant day, and not quite so hot.

19th.—Grey morning and forenoon, afternoon close and stormlike, with sudden gusts of wind both afternoon and evening.

20th.—Hazy in morning, but very fine by 9 A.M.; fine all day, and very hot in the afternoon and evening.

21st.—Rain at 6 A.M., fair but with high wind at 8 A.M., forenoon rather cloudy, afternoon looking stormlike, a short very heavy shower between 4 and 5 P.M., and strong gusts of wind more or less all day, and the temperature much cooler.

A fine pleasant week. The mean temperature about 9° above that of last week. The heat was rather oppressive on Monday the 20th.—G. J. SYMONS.

COVENT GARDEN MARKET.—AUGUST 22.

No improvement in business, the supply of home-grown fruit being nearly limited to Apples and Nuts. Large quantities of Grapes are now arriving from the Channel Islands.

From observation taken near London during forty-three years, the average day temperature of the week is 71.5°; and its night temperature 47.4°.

HERBACEOUS BORDER FLOWERS.

N page 135, in an article entitled "The Rose Year," "WYLD SAVAGE" states that he intends to make an herbaceous border, and would like some of your readers to give a list of herbaceous plants that must not be left out of it. At this season of the year when many herbaceous plants are in bloom a few general remarks on some of them may not be out of place. I will endeavour to name a few good old border flowers which are worth having in any garden; many of them may still be found in gardens where the more modern style of embellishment is not carried out. I myself hope others of your readers will contribute a list of old plants, for they are well worthy of more extensive cultivation.

First of all I will name a few dwarf plants that are suitable for the front row of the border next the grass or gravel. *Gentiana acaulis*, very dwarf, with large dark blue flowers produced in the spring and early summer months, grows admirably in damp situations, and when well established is a very attractive plant. The Christmas Rose (*Helleborus niger*), flowers in December and January, makes very pretty patches if the weather is not too rough; but if plenty of flowers are wanted of it for house decoration it is best to plant it in quantity, so that a frame and light may be placed over it when it begins to show flower. It also does well in 6-inch pots, and is useful for conservatory decoration, flowering freely in the same pots for two or three years in succession without repotting. *Campanula pusilla alba* and *C. turbinata* are two dwarf species, the former being very pretty when in flower in June or July. *Caltha palustris pleno*, or Double Marsh Marigold, is a plant with yellow flowers, very pretty in May and June. *Alyssum saxatile*, *Anubrieta purpurea*, and *Arabis alpina* are three well-known spring bedding plants, and good clumps of them are very telling in a mixed border. The *Arabis* makes a very pleasing bed from the middle of February until the middle of May, especially if single scarlet Van Thol Tulips and blue Crocuses are planted about 9 inches apart between the *Arabis*. It is easily increased by division after flowering, setting the pieces in rows, as many as are required for bedding, about 6 inches asunder, watering well until roots are emitted. The Evening Primrose (*Oenothera macrocarpa*) is a good old plant with large yellow flowers produced throughout the greater part of the summer. *Hepatica triloba rubra* and *H. triloba cœrulea* are two pretty spring-flowering plants. *Phlox Nelsoni* and *P. subulata* form charming masses of bloom in the spring; so also does *Saponaria ocyroides*. Any of the plants above named are good for the front of a border; nor should "WYLD SAVAGE" forget to have a few patches of *Mignonette*, *Snowdrops*, *Crocuses* of sorts, *Hyacinths*, *Jonquils*, double *Daisies*, and common *Bluebells*; also *Squills*, *Scilla præcox*, *S. siberica*, *S. campanulata*, and the Feathered *Hyacinth*, *Muscari comosum* and *monstrosum*, which are very pretty when in bloom.

No. 857.—VOL. XXXIII., NEW SERIES.

I will now enumerate a few taller-growing plants suitable for an herbaceous border, some growing a foot and others 2, 3, 4, and 5 feet in height, some of which require stakes to support the stems and flowers. What can be better for cutting from than good clumps of common white Pinks, Sweet Williams, Mule Pinks (*Dianthus hybridus*), Carnations, and Picotees? all of which can be increased by layers, cuttings, or seed. Plants of the common kinds of Pinks two or three years old will furnish hundreds of flowers. The Sweet William (*Dianthus barbatus*) is usually treated as a biennial, but sometimes it will keep alive and do well in the same place several years in succession. A good late summer plant is the Torch Lily (*Tritoma Uvaria*), known to many as the Red-hot Poker plant, clumps of it 4 or 5 yards apart in a long border have a very telling effect; so also is the Tiger Lily (*Lilium tigrinum*) and the common white Lily (*Lilium candidum*). Four or five bulbs of the two latter-named plants should be planted in patches 6 inches deep in enriched soil in the autumn, they will take care of themselves after.

A fine old plant for borders is *Iberis corifolia*; it strikes readily from cuttings placed in a close frame, but it takes two or three years before it has a telling effect. Plants of it that I have seen on the Cruciferous bed of a botanic garden, which have been in the same station for ten or twelve years, are perfect sheets of white when in bloom, 4 feet in diameter, resembling in outline and contour the famous specimens of fancy *Pelargoniums* that used to be so conspicuous at the metropolitan shows some twelve or thirteen years ago, as shown by Messrs. Turner of Slough, and Fraser of Lea Bridge Road Nurseries. It requires no training and no sticks for support. It is in bloom from the beginning of May till the end of June, a period of nearly two months, and taken altogether *Iberis corifolia* is one of the finest hardy plants I am acquainted with. *I. saxatilis*, *I. Garrethiana*, and *I. sempervirens* are also good sorts.

A very useful plant is the Sweet Woodruff (*Asperula odorata*); I have found that it does very well under the shade of trees when well established, and the foliage when cut and dried is very sweet-scented. *Dielytra spectabilis* is a well-known useful plant for borders, good also for forcing. *D. eximia* is a pretty dwarf plant with lacinated foliage, the flowers only rising about 6 or 7 inches in height; it may occasionally be seen in old cottage gardens in company with such plants as the old hardy *Fuchsias* and *Monkshood* (*Aconitum Napellus*), the *Fritillaria* or Crown Imperial, Canterbury Bells, Rockets, Lavender, perennial *Asters* or *Michaëlmass Daisies*, London Pride (*Saxifraga umbrosa*), Golden Rod (*Solidago altissima*) 4 or 5 feet in height, Lupines, Solomon's Seal (*Polygonatum multiflorum*), Lily of the Valley, *Mignonette*, *Marigolds*, and *Brompton Stocks*, all of which are useful old plants.

Delphiniums, of which there are many varieties, are useful for cutting. *D. formosum* is still as free and hardy as any I know, but *D. Hendersonii* has finer flowers. *Saxifraga granulata*, *S. paniculata*, and *S. crassifolia* are good border flowers; the latter has bold handsome foliage.

No. 1509.—VOL. LVIII., OLD SERIES.

The Meadow Sweet (*Spiraea Ulmaria*) and Dropwort (*Spiraea Filipendula*), *Veronica spicata*, the Virginian Spiderwort (*Tradescantia virginica*), *Statice Gmelini*, *S. latifolia*, the flowers of the two latter-named are useful for mixing with Everlastings for winter decoration; *Oenothera biennis*, growing to 5 or 6 feet in height, the flowers of a bright primrose colour, and beautifully scented; some of the different kinds of *Iris*, *Columbines*, *Antirrhinums*, *Pyrethrums*, *Pæonies*, *Pentstemons*, and *Gladioluses* are all suitable for planting in borders.

A few more good plants, though some of them are seldom met with, are *Dictamnus Fraxinella*, 2 feet in height; *Echinops ruthenicus*, with Thistle-like heads; *Onosma taurica*, a plant of the Boraginaceae family with bright golden flowers; *Corydalis nobilis*, *Chrysocoma linoxyris*, *Liatris squarrosa*, *Lobelia cardinalis*, *Linum flavum*, *L. perenne*, the latter a beautiful blue-flowering plant; *Monarda didyma*, the scarlet flowers and leaves of which have a beautiful perfume; *Lychnis chalcedonica*, *L. dioica rubra*. *Iris fetidissima*, with its bright red seeds in the capsule like Holly berries (the variegated kind is also ornamental), and *Centranthus ruber* are all useful to cut from to mix with the "handful of flowers" that is often asked for. *Campanula carpatia*, *C. carpatia alba*, and *C. coronata* make splendid border plants, seeds of which if sown now will make flowering plants next year. *Coreopsis lanceolata* and the Leopard's Bane (*Doronicum austriacum*) are two fine yellow-flowering plants; also the Day Lily (*Heimerocallis flava*). *Funkia ovata* and *F. subcordata* have bold-looking and handsome foliage, as may be seen by their use in the London parks; *Achillea Millefolium roseum* and *A. Millefolium aureum* are pretty in June, and *Anemone Honorine Jobert* is a capital September-flowering plant.

A good deep soil and well enriched with decayed manure is necessary before planting a border with herbaceous plants. It may be taken as a guide that soil that will produce Potatoes or Cabbages well will also suit most herbaceous plants. They should be planted so as to leave ample space between them for hoeing and raking in summer time; room may also be left for having good patches of annuals—Stocks, Zinnias, Gaillardias, Wallflowers, Asters, Pansies, Hollyhocks, Dahlias, and Chrysanthemums, the Pompon section being very useful; also a few scarlet Geraniums, Salvias, Heliotropes, &c.; for a border made exclusively of herbaceous plants has towards the end of summer a very dull appearance. None of the plants I have named are of recent introduction; all have conspicuous flowers, and are well known to many. There are many more good, but these are a few out of the many good old garden plants, and if "WYLD SAVAGE" cannot obtain all of them I would recommend that the following should not be left out of his herbaceous border:—

<i>Iberis saxatilis</i>	<i>Funkia subcordata</i>	<i>Linum flavum</i>
<i>Anubria purpurea</i>	<i>Saponaria ocyroides</i>	<i>L. perenne</i>
<i>Oenothera macrocarpa</i>	<i>Carnations</i>	<i>Fuchsias</i> (hardy)
<i>Echinops ruthenicus</i>	<i>Pæonies</i>	<i>Tritoma Uvaria</i>
<i>Dictamnus Fraxinella</i>	<i>Dahlias</i>	<i>Coreopsis lanceolata</i>
<i>Gentiana acutis</i>	<i>Heliotropes</i>	<i>Veronica spicata</i>
<i>Heimerocallis flava</i>	<i>Arabis alpina</i>	<i>Polygonatum multiflorum</i>
<i>Delphinium formosum</i>	<i>Alyssum saxatile</i>	<i>Scilla campanulata</i>
<i>Lupinus polyphyllus</i>	<i>Campanula pusilla alba</i>	<i>Saxifraga crassifolia</i>
<i>Dicentra spectabilis</i>	<i>C. carpatia</i>	<i>Pinks</i>
<i>Solidago altissima</i>	<i>C. carpatia alba</i>	<i>Pansies</i>
<i>Monarda didyma</i>	<i>Anemone Honorine Jobert</i>	<i>Hollyhocks</i>
<i>Statice Gmelini</i>	<i>Doronicum austriacum</i>	<i>Chrysanthemums</i>
<i>Spiraea Filipendula</i>		

—A. HARDING.

STRAWBERRIES ON LIGHT SOIL.

As an amateur I venture to send you a few notes on Strawberry culture which may interest some of your readers. About five years ago I took possession of a garden in the eastern counties with a southern aspect, having full exposure to the sun and partially sheltered by surrounding buildings, which, however, greatly aggravate the destructive force of southeasterly winds in the spring and south-westerly gales in autumn. The soil was very poor and light, with gravel at 2 feet from the surface; and the existing Strawberry beds being evidently exhausted I at once dug them up and trenched the ground, working in plenty of good farmyard manure and spread 3 inches of clay over the surface, which after being exposed to frost all the winter was forked-in the following spring, when runners of all the best kinds I could procure were planted. All through the growing season the young plants were watered when necessary, mulched, and duly looked after, and by the autumn were well established for fruiting the next year, when the crop fully repaid the trouble taken with it.

After gathering the fruit the plants were watered and kept free from runners, &c., and in the winter a second dressing of clay was given. The second season the fruit was more abundant than the first; but though the total weight was greater the individual berries were not so fine, and consequently only half the beds were left for the third season and a fresh plantation of runners made. The three-year-old plants received the same attention as the new plantation, but the fruit of the latter proved so superior in every way that I shall not again allow any plants to stand over the second season, and should be inclined to renew all annually, except for the fact that the fruit from the two-year-old plants comes about a week later than that from the runners, and thus helps to prolong the season—a most desirable object in Strawberry culture, especially with the British Queen variety, which has no later kind to follow it at all approaching it in flavour.

As to varieties, Black Prince is the earliest, with nothing else to recommend it. Keens' Seedling is the best early sort, though complaints are sometimes made of its being a bad bearer, which I believe is owing to carelessly taking the runners from the strongest instead of the most fruitful plants. Alice Mand is good and a free bearer; Oscar and Roden's Early Prolific are worth trying, the latter in some seasons being a few days earlier than Keens'.

For mid-season, Lucas has proved the best, being large and when quite ripe very richly flavoured. President is very large, and, though hardly equal to Lucas, excellent for preserving. Sir J. Paxton and Sir Harry are also good. Vicomtesse Héricart de Thury is an abundant bearer of medium-sized fruit. Rivers' Eliza seems to require some special treatment, as it does not prove equal to what I have tasted from other gardens. Can any of your readers say how it ought to be grown?

The best late sort is British Queen, surpassing all others in flavour, and when fully ripened perhaps the finest fruit grown in English gardens. Its leaves are very liable to injury from red spider, and after the fruit is gathered, if intended to stand a second season, it should receive special attention as to watering and mulching. Dr. Hogg and Mr. Radclyffe seem to be mere varieties of British Queen, and no improvement on it. Carolina Superba is another variety of the same strain but distinct, being much sweeter and richer than the Queen. Frogmore Late Pine proved no later than British Queen, and decidedly inferior to it. Elton and Eleanor are later but acid, and the latter, though large and handsome, is too coarse to eat after tasting the Queen. A variety that would come in after the Queens are over, and anything like equal them in flavour, would be a decided boon.

As to recent novelties I only know of one worth recommending, named Loxford Hall Seedling, which Messrs. Veitch are now sending out. It combines the richness of one of its parents (British Queen) with the constitution of the other (La Constante), and will doubtless succeed in many places where the Queen fails. I intend growing it myself, and advise my friends to try it.

On good heavy soil anyone can grow abundant crops of Strawberries, even on the lazy-bed system; but on light soils I am persuaded that success can only be secured by carefully preparing the ground, and if very light adding some heavy loam or clay. Plant early and far apart, water when necessary, and mulch, which saves much watering; and last, but not least, allow no plants to remain over the second season.—ESSEX.

AUTUMN ROSES.

"WYLD SAVAGE" has recently referred to autumn Roses. I can fully confirm all he says on our queen of flowers. On the 14th and 15th of August I cut magnificent blooms of *Maréchal Niel*, *Gloire de Dijon* (as usual always first and last to flower), *President Grevy*, a most beautiful dark Rose, of unusual excellence as an autumn Rose; indeed, it seems specially adapted for that purpose, it not having given me any good blooms till now. Old John Hopper again is giving fine blooms, and last year fine blooms of it were produced from a south border in my rosery, for, as "WYLD SAVAGE" says, I do not grow my Roses all in one place, those doing best now being on a north border.

Paul Neron, though he is a coarse Rose in summer, is now throwing me some really magnificent blooms of beautiful form; *Capitaine Christy*, too, has just been doing good service. I cut some really beautiful blooms of this lovely Rose on August 15th. *Madame Victor Verdier*, *Madame Charles Wood*, *Sénateur Vaisse*, and *Souvenir de la Malmaison* have

been doing splendidly, the latter being now covered with fine blooms. I cannot omit to mention *Perfection des Blanchés*, although of no use as a show variety. It is covered with buds and blooms, and looks as if it would continue flowering for a long time to come; indeed, there is no variety I know so useful for cutting blooms from for the drawing-room and other places where Roses are much used for decorating. Louis Van Houtte is now blooming freely. Many other varieties I could mention, but I must content myself with the few already named.—SHROPSHIRE GARDENER.

KALOSANTHES COCCINEA CULTURE.

As greenhouse plants of easy culture, suitable alike for the small house of the amateur and the imposing conservatory of the aristocrat, *Kalosanthus* are specially recommendable. Large specimens also have a telling effect in collections of plants at the summer exhibitions. Their neat fleshy leaves and compact growth render the plants anything but unsightly even when not in flower, but when covered with their glowing trusses they are really gorgeous; they continue also a long time in beauty. Quite small plants in 4 or 5-inch pots, each having one stem terminating with a head of flowers, are extremely useful for many purposes of decoration; and plants in proportionally larger pots, with from six to twenty and more heads of flowers, are splendid objects where large plants and rich masses of colour are required.

For producing small plants for flowering next summer cuttings should be inserted at the present time. The extremities of strong healthy shoots should be cut off about 4 inches in length, an inch of the base of each cutting being divested of leaves. The cuttings after being made should lie on a shelf for a few hours for the sap to dry-up and the wounds to heal. Each cutting should then be firmly inserted in the centre of a small pot in a compost of loam, crushed bricks, and silver sand, and be placed on a shelf in the greenhouse, and not shaded from the sun. The soil must be kept moderately moist but by no means wet, and each cutting will emit roots speedily. Water may then be given more freely for a short time until the pots become quite filled with roots, when it must then be given less copiously, and be gradually withheld as the dark days of winter approach. The plants must remain in the same pots on a dry light shelf throughout the winter, and for three months (November, December, and January), scarcely any water should be given to them, but the leaves should be permitted to become limp and flaccid, and if they lose their bright green tint no harm will result. The partially-drying process induces the flower heads to form in the tips of the plants, and as the spring approaches they may be plainly felt, each tip when pressed between the finger and thumb feeling as if it contained a small nut. When in that state and the days become lighter and longer the plants may be watered again, and the limp leaves will become rigid and their pale brown colour will change to a lively green.

They may then be shifted into their flowering pots, 48's, potting them firmly in turfy loam and a little old dried cow dung, incorporating also crushed bricks and charcoal freely. The plants must still have a very light place on a shelf in the greenhouse, and must have plenty of air to keep them dwarf and sturdy in habit. In due time the flowers will expand, and not many plants will be found more useful nor be more generally admired. A dozen or a hundred of such plants—as may be required—should be grown in all gardens where attractive flowers are coveted during the early summer months. Few plants can be produced more easily, and scarcely any flower with greater certainty when managed as above described, but it is important that no delay occurs in inserting the cuttings. I have occasionally had good flowering plants from cuttings inserted in September, but August is the better month.

When the plants have ceased flowering water should be partially withheld, and they should be cut-down to within 4 or 5 inches of the root. Fresh growths will then form, which must be thinned-out to the number required, and the plants be repotted, removing a portion of the old soil. Growth should be encouraged until October, when the plants should be partially dried as before. When cut-down early and well managed the young growths will flower the following year, but otherwise they will not all do so; and when really fine plants are required it is well to have two sets of them, so that a clear summer's growth can be afforded—one set of plants flowering, and the others growing for the following year's display. Satisfactory results are then sure to follow, and plants produced

which will do credit to any cultivator and add beauty to any conservatory.

A few attractive sorts are *coccinea superba*, *splendens*, *Napoleon grandiflora* and *miniata*, the first named being, perhaps, the best of the quartet.—EX-HIBITOR.

TEBBS' UNIVERSAL TRAVELLING POT.

UNDER the above rather formidable yet expressive name a paper flower "pot" has been submitted to us by Messrs. Blake and Mackenzie, which we regard as a very simple, sensible, and serviceable invention. The following advantages are claimed by the inventors for this novel flower pot—great saving of

Fig. 37.
Showing plant placed in one of the pots.

Fig. 38.
Ready for market, &c., or carrying by hand.

time in packing, as no mossing-down is required. Plants packed in these pots occupy considerably less than the usual space, and, being unbreakable, can be packed close together, thus making a saving in packages. The plants being turned

Fig. 39.
Plant packed for sending long distances.

out of their ordinary pots reduces their weight to nearly one-half, thus reducing the important item of carriage considerably. They are also cheaper than ordinary pots—an important consideration where large quantities of plants are sent away, as the pots they have been growing in can be retained for home purposes only. Where large quantities of plants are sent out for immediate planting or bedding, or for market purposes, the saving of labour and cartage will be considerable.

The above engravings show how the pots are to be used—viz., turn a plant out of the ordinary flower pot, and while holding the ball in one hand place one of the paper pots over it, press it down, and fold down the flaps; these keep the whole in shape. They are made of strong brown paper lined with a waterproof material to retain the moisture about the roots, thus preventing the plants suffering through any delay in transit. Upon arriving at their destination they can be replaced into the same sized pots from whence they were originally taken, or shifted into larger, or planted out as required. The paper pots are made at a cheap rate of various sizes from 2½ inches to 6 inches in diameter, and larger sizes will afterwards be introduced if required.

THE ROSE ELECTION.

VERY hurriedly a line in reply to "H. C.'s" suggestion as to the limit of seventy-two varieties instead of forty-eight. I think I recognise him and wish I could meet his views, but already several of those named have returned their voting papers, though I am sorry to add that thus far the nurserymen are sadly in arrears, and comparatively few have returned lists. I am afraid the suggestion coming so late would rather interfere with the present election. I have no objection to try and meet him this way. Very few amateurs, I fancy, ever stage seventy-two, and it would perhaps interfere with the election

to suggest seventy-two to any but the largest amateur growers. If "H. C." will use his influence with, say, a dozen of the southern growers, getting them to name seventy-two, I will on receiving the replies from him tabulate the results after the forty-eight election.

To the forty-eight exhibition Rose election I shall be glad to have replies without delay. I propose now to leave the date for closing open to the middle of September, and want replies from successful exhibitors, marking—1st, the best twelve exhibition Roses; 2nd, the next best twelve, and then the next best twenty-four. If placed in order of merit, so much the better.—JOSEPH HINTON, *Warminster*.

GRAPES.

SOME time ago a Grape was brought out (I think by Messrs. Veitch & Sons) called the Champion Muscat. Referring to their catalogue just issued, as well as to those of some other nurserymen, I find no mention is made of it in their list of Grapes. Can anyone tell me why this is the case? as here it is one of the very finest both in bunch and berry that I ever saw—it is simply grand, and the flavour is superb; in my estimation it is the best Grape I ever tasted. I have seen it described as a grizzle in colour, here it is a rich red purple, certainly not a black, but a beautiful colour with a light bloom. It is a strong grower, and ripens well in a cool house or even a ground vinery. Taking it altogether it is the most desirable Grape I have. Then why is it no longer in the lists of Grapes?

My Venn's Muscat has proved itself totally distinct from the old Muscat Hamburg, its growth being exceedingly strong and it is extremely prolific. Even now, though the fruit is nearly ripe, fresh bunches are continually appearing on the laterals. The flavour is different to the Muscat Hamburg, and it ripens well in a cool house. The berries are not so large as the old variety, but still of fair size, therefore I place it as good, and later than the Muscat Champion. I have also a house of Mrs. Pince's Muscat, a wonderful crop and colouring well. How is it that one scarcely ever sees this fine Grape well finished? Madresfield Court is doing well, but does not come up to the foregoing. I have planted a Duke of Buccleuch, but it seems delicate. Has anyone done well with it? It is a weak grower with me, but I think very highly of it as a white Grape, and Pearson's Golden Queen as an amber from what I have seen and tasted; but, as I have said at the beginning of this article, the Grape of Grapes for me is the Champion Muscat.—HARRISON WEIR, *Weirleigh, Brenchley, Kent*.

THE POTATO DISEASE IN SOUTH WALES.

I HAVE seen Potatoes grown and Potatoes diseased in many parts of the country, but I never saw them so badly affected as they are in this neighbourhood this season. Until about the middle of July there were no signs of spot or blemish on stem or tuber, but then we had much muggy mild wet weather; and since then Potatoes have gone bad on all soils in a most violent manner. Many of them became quite black and decayed in the stems in a few nights, and the roots were affected as quickly. Rivers' Royal Ashleaf Kidney was one of the worst, and although the tubers were lifted and dried and stored in a shed carefully, many of those which looked perfectly sound have since become soft and decayed. Gloucestershire Kidney was not quite so much decayed as Rivers', but the Cornish Kidney is much worse. Prince of Wales, Giant King, Early Mealy, Model, Robson's Champion, Walnut-leaf Kidney, and Snowflake are so bad that not over ten per cent. of them are fit for use. The only two kinds which remain good are Breeze's King of the Earlies and Climax. Like all the others the crop of these is heavy, and it is to be regretted they are not drier when cooked. King of the Earlies especially is very seldom mealy. Our late varieties, which include Paterson's Victoria, Paterson's Blues, Regents, Rocks, and Sutton's Red-skin Flourball, are not lifted yet, but I fear they will be as bad as the others, as the stems are quite black.

Several writers have advised lifting the roots as soon as the stems show signs of becoming black, let the tubers be ripe or unripe. With the exception of Rivers' not one of ours was ripe when the stems became black, and many of them not half swelled. As yet I have failed to learn, either by practice or reading, that lifting these half-swelled Potatoes is the best thing to do to preserve them when attacked by the disease. Wet weather is the sure propagator and promoter of disease. A few days' rain will start decay, and should wet continue

it will progress rapidly; but when dry weather follows the disease is checked and ceases to spread, while the tubers continue swelling and become matured. But what is the result when the tubers are lifted at the first appearance of disease before they are much more than half swelled or half ripe? Simply this, such Potatoes are never good for food; and as for seed, they are not fit to plant anywhere. How can they? What kind of produce would any gardener expect from such as Peas or any other kitchen-garden seed which was gathered before it was half grown and put away into some shed to shrivel up and dry? Plant Potatoes next year from those lifted before they were matured this season and they may grow, but their growth will be weak and their constitution weaker, and therefore much more subject to disease. For these reasons I am never in too great a hurry to lift Potatoes until I am sure they are ripening, even although a few more of them should fall a prey to the plague.

In a wet season like this I do not think situation is of much avail to ward off the disease. We have Potatoes growing in three different gardens, in light soil and heavy soil, and they are all much the same. In the cottage gardens, where some are high, some low, some surrounded by trees and others fully exposed, none have escaped. The farmers have not begun to lift their field crops yet, but I see the stems there are also black and withering up. Altogether it is one of the most unprosperous Potato years that has ever been known about here; and I doubt it is not much better all over Wales, as Mr. Pettigrew, the Marquis of Bute's gardener at Cardiff Castle, and Mr. Slater, Lord Cawdor's gardener at Stackpool, told me the other day that there was great cause for complaint in those districts.—J. MUIR, *Margam Park*.

THE ROSE'S HISTORY.

THE Rose was known more than 2500 years ago, for it is mentioned both by Solomon and Isaiah. It could not escape their notice, for it is common in Judaea. Sandys, one of our earliest travellers, found Roses wild and abundant near Jerusalem; and Doubleday, another early traveller, mentions that there were hedges formed of Rose bushes. In the flower market at Athens it held a prominent position, for the Greeks esteemed it the most beautiful of flowers, and therefore appropriately dedicated it to Venus. All the Roman writers on the culture of the soil include special directions for the propagation and management of Roses. As the emblem of youth the Rose was dedicated to Aurora, of love and beauty to Venus, of danger and instability to Cupid. It was given by the latter as a bribe to Harpocrates the god of silence; whence perhaps originated the custom, of which we are told by Rosenbergius, that obtained among the northern nations of Europe, of suspending a Rose from the ceiling over the upper end of their tables when it was intended that what passed at their entertainments should be secret. And this undoubtedly is the origin of the common expression "Under the Rose." The ancients tell us that Roses originally were white, but were changed to red by the blood of Venus when her feet were lacerated by their prickles in her attempt to protect Adonis from the rage of Mars. Theocritus, and Bion, however, are of opinion that it was the blood of Adonis himself that altered their colour. Another tale relates that Cupid, leading a dance in heaven, stumbled and overset a bowl of nectar, which falling upon the earth stained the Rose. Ausonius has made the Rose blush from the blood of Cupid. Busbequins informs us that the Turks have a similar superstition upon the subject, and believe that Roses originated from the sweat of their prophet Mahomet. Nor has the ingenuity of monkish writers been at a loss to stamp Roses in some measure with divinity, though in a different manner. Marulus tells a story of a holy virgin named Dorothea, who suffered martyrdom in Caesarea under the government of Fabricius, and who converted to Christianity a scribe named Theophilus by sending him some Roses in the winter time out of Paradise. A golden Rose was considered so honourable a present that none but crowned heads were thought worthy either to give or to receive it. Roses of this kind were sometimes consecrated by the Popes upon Good Friday, and given to such potentates as it was their particular interest or wish to load with favours; the flower itself being an emblem of the mortality of the body, and the metal of which it was composed of the immortality of the soul. Boethius says that William King of Scotland received a present of this sort from Pope Alexander III., and Henry VIII. is recorded to have had a similar gift from Alexander VI. The

seal of Luther, which is well known to have been a Rose, may have been symbolical of the same things as the golden presents of the Popes. Roses were employed by the Roman emperors as a means of conferring honours upon their most famous generals, whom they allowed to add a Rose to the ornaments of their shields, a custom which continued long after the Roman empire had ceased to exist, and the vestiges of which may yet be traced in the armorial bearings of many of the ancient noble families of Europe.

It is a mistake to suppose that double Roses are of somewhat modern origin, since they are particularly mentioned by Herodotus, Athenæus, and Theophrastus, and more especially by Pliny, who enumerates several sorts, among which is a centifolia. It is remarkable that Pliny does not mention the Rose of Pæstum, nor any growing in that neighbourhood. This omission makes it impossible even to guess at what was meant by the "biferi Rosaria Pæsti." The only Rose Mr. Woods found about Pæstum was *R. sempervirens*.

The name Rose is derived by De Theis from the Celtic *rhodd* or *rhudd*, signifying red, whence, he thinks, have originated the synonymous names *rhos* in Armorican, *rodon* in Greek, and *rosha* in Slavonian.

The Rose was first assumed as a device by Edward III.'s sons. John of Gaunt, Duke of Lancaster, adopted the red Rose, and his brother Edward, Duke of York, adopted the white Rose. By marriage in 1486 the two Roses were united and became the royal badge of England. The 67th Regiment, called also the South Hampshire Regiment, bear what is termed "The Hampshire Rose" as a badge on their colours. The legend is that it was given to the Hampshire trained bands by Henry V. for their gallantry at the Battle of Agincourt. Mr. Reynolds Hole says that the Rose, born in the east, has been diffused, like the sunlight, over all the world. A flower, writes Pliny, known to all nations equally with wine, Myrtle, and oil. It is found in every quarter of the globe—on glaciers, in deserts, on mountains, in marshes, in forests, in valleys, and on plains. The Esquimaux, as Boitard tells us in his interesting "Monographie de la Rose," adorn their hair and their raiment of deer and seal skin with the beautiful blossoms of the *Rosa nitida*, which grows abundantly under their stunted shrubs. The Creoles of Georgia twine the white flowers of *Rosa lævigata* among their sable locks, plucking them from the lower branches of climbing plants which attach themselves to the garden trees of the forest, and bloom profusely on their boles and boughs. The parched shores of the Gulf of Bengal are covered during the spring with a beautiful white Rose, found also in China and Nepal; while in vast thickets of the beautiful *Rosa sempervirens* (a native also of China) the tigers of Bengal and the crocodiles of the Ganges are known to lie in wait for their prey. The north-west of Asia, which has been called the fatherland of the Rose, introduces to our notice the *Rosa centifolia*, the most esteemed and renowned of all, with which the fair Georgians and Circassians enhance their fairness.

In modern times Lyte, writing in 1578, says the calyx was then called "the five brothers of the Rose, whereof two have beards, two have none, and the fifth hath but half a one." He says the white Rose was the *Rosa Damascena*; the red Roses were called "of the common people Double Roses;" a third kind were called Roses of Provence and Damaske Roses; a fourth kind smelling of cassia was the Civet Rose or Bastard Musk Rose; and a fifth the Musk Rose. Parkinson, in 1629, states that he had "thirty sorts at the least, every one notably different from the other, and all in the garden fit to be entertained." The double yellow, he adds, was introduced from Constantinople "by Master Nicholas Lete, a worthy merchant of London;" but his trees failed, and it was subsequently established here by another merchant, "Master John de Franqueville." Lobel, in 1581, published engravings of ten species, but Dr. Lindley in his "*Rosarum Monographia*" particularises 101 species. There are now probably more than three thousand varieties, for in 1829 Desportes published a catalogue of 2562.

WILD FLOWERS FOR DECORATION.

PIMPINELLA SAXIFRAGA (Burnet-leaved Saxifrage) has umbels of exquisite white flowers, compact in growth; the stem is firm, and the whole plant fairy-like. Just now I have vases, &c., filled with it and Purple Heath; Ferns as foliage. It grows most abundantly on Red Hill, and no doubt on most commons; looked down upon the flowers seem like most delicate

lace. I find wild flowers most effective when massed. Snow-drops dotted about in moss, Cowslips and Bluebells, Primroses and their leaves, Forget-me-nots and Sweet² Woodruff, Ox-eye Daisies, Bluebottles, fresh grass flowers, and a little scarlet are charming. For foliage nothing can be prettier than Tansy (such lovely shades of yellow-green), Cow Parsley, or Earth Nut.

Of all our wild flowers Ox-eye Daisies are the most effective for decoration. They set off exotics well, and last a very long time.—BOTANIST, Red Hill.

OUTDOOR PEACH-GROWING.

It is to be feared that not only is the Peach crop scanty this year, but that the trees themselves are in many cases irreparably injured. Such I am sorry to say is the case with many of them here, although they were covered with frigi domo every cold night from the 27th of February till June. They also had coping-boards more than a foot wide above them, and I am almost positive that the frost never actually touched them once. We have generally had much lower temperatures and the trees have gone through unscathed, but the lower temperatures have seldom lasted so long, and Peaches have rarely been so forward as they were last February. On the 27th of that month many flowers were fully expanded; the covering was put on them for the first time, and we had 11° frost; 12° followed the night after, and this was the lowest temperature registered during the season. But much dull weather with east wind came next, which had the effect of producing a semi-congelation of sap, and causing the trees to remain in a glorious mass of bloom for a longer time than I ever remember to have noticed before. It is always a bad sign when the bloom remains long on fruit trees, they must be moving forward or they will go back. The cutting east wind rendered progression impossible, therefore they did go back, and the memory of the gorgeous bloom is nearly all we have left to pay for our trouble.

Well, what is to be done? Shall we give it up? Oh, no! I think to be successful three years out of four with outdoor Peaches in this country is much more than we have a right to expect. We may not have such another untoward season during the next decade. "But it takes a decade to grow a Peach tree to a fair size." I know it does according to one system of growing it, but there are at least two other systems by which a wall may be completely furnished in two or three years, and they both have the advantage of being much more simple than the orthodox plan. One is the cordon, and this is, perhaps, as good as any where the soil is light and poor; the other system I do not know what to call it, and must therefore attempt to describe it. Maiden plants are placed against a wall upright, about 4 feet apart, and the laterals, instead of being stopped as for a cordon, are tacked-in at regular intervals and obliquely on each side. To make the most of the time the trees must be planted as early in November as it is safe to move them, and the knife must not be used on them till the following midsummer unless to remove an odd shoot from the back of them. Any superfluous shoots may be partially disbudded in spring, and finally removed with a clean cut when the leaves are fully grown. It is possible with this system to have a wall fully covered and a fair crop of fruit in little more than two years and a half from the time of planting maiden trees.

Although all the older trees have suffered more or less from the severity of the weather, none of the maidens planted last autumn have done badly, but are now in excellent health, owing, I think, to their having received a check through removal, and consequently starting into growth at a more favourable season.

I have an idea of planting several screens of Hornbeam across the borders at right angles with the wall as a shelter from the east wind.

For constitution, quality, and succession, perhaps the following half-dozen sorts are as good as any—viz., Early Beatrice, Early Louise, Hale's Early Grosse Mignonne, B. Negarde, and Barrington. Three good Nectarines are Lord Napier, Violette Hative, and Pitmaston Orange.—WILLIAM TAYLOR.

TROPEOLUM SPECIOSUM.

I NOTICED that at a late meeting of the Floral Committee Mr. Wilson exhibited a spray of this charming creeper, which he had grown successfully in a shady place. I have been equally successful in growing it in the full sun, so much so

that my friends in Scotland from whom I procured the bulbs were very much surprised to find that it had flowered with me, as it has done, the first year. I am therefore hopeful that we may succeed down south with it as well as in Scotland, and I intend myself to try it in various aspects this next season. In Scotland it is almost a weed; in fact I heard of one place in which it was treated as such. But we have not arrived quite at that yet, still it is satisfactory to find that it can be grown in the south.—D., *Deal*.

HOW TO MAKE MUSHROOM BEDS.

THE season is near at hand when those who intend to grow Mushrooms during the winter will have to do their best to procure good materials for making beds to grow this delicious esculent. No doubt many will say there are plenty of instructions before the public already whereby the merest tyro can find sufficient information, and that practical men do not need lectures on this head. All very well; but still I may have my say about the affair, being no novice in the matter. Thirty years ago I had Mushroom beds in a brick pit where Melons were grown during summer, and in which a small pipe gave surface heat. This pit was cleared during September preparatory to forming the Mushroom beds. Those beds yielded a long succession of good Mushrooms, and so strong in them was the run of the spawn that it came right through the brickwork, and very good Mushrooms grew all along where the path joined the wall.

During last autumn I prepared materials much in the same way as I had done thirty years ago, but this time the bed was made in an outhouse in which we could not command any heat. This bed was made up about the middle of October, and, as in the former case, I had the dung from the bottom of a deep pit into which the dung from the stables had been thrown during the summer months. Eight or ten cartloads of this manure had become white while pressed down in the dung pit; during this time it had become one mass of white mouldiness. We forked out the longest of the litter, not rejecting the short bits of straw, and took good care while it was laid in a heap outdoors that no rain fell upon it. When it gave evidence there would not be any violent heat in the bed when made up, we had it taken indoors. About three good cartloads were placed in one bed, having about four barrowfuls of good fresh soil mixed with this manure, thus giving the bed substance and firmness after being well trodden down, which is much better than beds made up entirely of dried horse droppings, in which case they are often a mere soft fluffy heap of short dry dung, and but seldom bear over half the time beds generally do when prepared as stated above. Our bed was about 18 inches deep, and as the first violent heat in the dung had been spent while in the dung pit we had no violent heat in the bed, and therefore we could spawn it the sooner. This bed began yielding rather sparingly early in December, but afterwards yielded abundantly, and continued doing so for seven months. Always give a good depth to Mushroom beds, they repay well for it; and do not make them with damp materials, which often give off a violent heat at first and short yieldings.—G. DAWSON, *St. John's Nursery, Worcester*.

VARIORUM NOTES ON ROSES—PERENNIALS.

I CAN endorse much that "WYLD SAVAGE" says about autumn-blooming Roses. Pierre Notting does not do well in the summer, because, like most dark Roses and all that have much tint of purple, it cannot stand sun. The same is especially true of Mons. Boncenne, which is rarely seen good except shaded. Here I never cut a perfect bloom unless there has been nearly a fortnight of dull weather. For perpetual blooming recommend me to La France; there is no other Rose to touch it except Gloire de Dijon and the old Monthly. The reason why Emilie Hausburg so often does best in autumn is that its bud is round instead of conical, and the outer petals are hardly large enough. There is no more perfect-shaped Rose when it has time given it to expand, but hot dry weather and long sunny days do not suit it. Another Rose he has not mentioned is Thomas Methven, another of the round-budded flowers, but one of the most beautiful at times, still a hard opener in summer. Again, for autumn-blooming there are three Noisettes—America, Céline Forestier, and Triomphe de Rennes; and why should we omit the old Général Jacqueminot? Charles Lefebvre is another of those Roses which require shade in the middle of the day. Madame Victor Verdier, Alfred

Colomb, and Marie Baumann are generally better in summer than autumn; but as a rule few Roses can stand early pruning, then severe weather in March and April followed with hot dry weather in May and June, and where Roses are pruned early in early soils many of the Roses come to maturity too soon.

"WYLD SAVAGE" has in his notes on Roses touched from time to time on several points on which I feel inclined to add a few remarks. First as to disbudding. I am sure that this may be overdone, especially as it adds much to the merit of a stand in close competition to see good extra buds and foliage. Some few kinds, as Baroness Rothschild, Paul Neron, and a few others, if I may use the expression, seem to disbud themselves, as it is seldom that one sees more than one bud on a stem; but some of our strong-growing sorts, as John Hopper, can stand the extra buds without injuring the blooms.

Again, is it not a mistake for amateurs who wish to exhibit in thirty-six and forty-eight to grow too few kinds? There are many neglected sorts, as François Louvat, M. Boutin, Duchesse de Morny, Madame Caillat, Berthe Baron, Cécile de Chabillant, Duchesse de Caylus, Madame C. Wood, and others I could name which ought to be more grown. I agree with him that Annie Wood is capricious, but I occasionally cut Roses from it worthy of any stand. Madame Clemence Joigneux and Antoine Ducher are another pair of good old Roses which are in danger of being cast on one side, though perhaps neither of them will do for exhibition purposes. Another Rose I have seen very good is Clement Marot, and also Lord Suffield. No Rose offener disappoints me than Mons. Noman; the least damp weather and the petals glue together. The same is the case with Madame Lacharme. I have not, unfortunately, been in the way of seeing new Roses this year, and should like to know if any of the new ones beat Marquise de Castellane, Etienne Levet, and Miss Hassard in their colours: the latter seems to me a real acquisition. Shall I be talking treason when I say I cannot think Cheshunt Hybrid can ever be a very perfect exhibition Rose? It grows well with me, blooms freely, but always hangs its head and is rough and quartered. I know Mr. George Paul sets great store by it, but I think he has sent out many a better. It seems to me, if that can be the case, as if it had three crosses of blood in it—a cross between a Tea and a Bourbon, crossed again with Duke of Edinburgh or a Hybrid Perpetual of that class. At all events there is so little of the true Tea in it that it can hardly be classed amongst the Teas. Wilson Saunders seems a very fine-coloured Rose and stands the sun well. I should like to know other persons' experience with regard to it.

A question has been asked and answered as to zinc labels. Is it not more likely true that shoots on which labels are fastened die away because persons are too fond of keeping in the old wood on which the label is fastened instead of cutting it away and tying a new one on to a fresh shoot? The older shoots on trees, especially on the Manetti stock, are more apt to die away than younger. Indeed, as I have before said in your Journal, it is the nature of Roses to recuperate themselves from the base; and if you wish to have good blooms and strong shoots always cut away all shoots that are more than two years old. This of course does not apply to standards or well-trained trees.

What course would "WYLD SAVAGE" recommend me to adopt to grow Tea Roses in the open ground in this part of Yorkshire? Some do fairly well, but they are generally disappointing. I will in return give him a list of perennials for his perennial border; but I shall promise him it shall not be a very long one, for let him beware of the snare of trying to grow too many kinds on the same border and same aspect. Add to those he has named good varieties of Pentstemons, and Delphiniums, and Gladioli; and for early blooming Antirrhinums, Sweet Williams, with Polyanthuses, Auriculas, and Anemones for front of the border, to be followed afterwards with Sedum Fabaria or spectabile and other dwarf Sedums. Another plant to be added, though not strictly perennial, is Myosotis dissitiflora; and patches of Golden Thyme, if not allowed to overgrow, look well in front. But the proper place for a perennial border is in front of a shrubbery and not too near the house, in my opinion.—C. P. P.

TRIGONIDIUM OBTUSUM.

THIS is a pretty though small Orchid, native of tropical America, with few coriaceous leaves and orange-brown flowers. This genus is scarcely known in cultivation, and botanically is quite distinct from every other. It belongs to the Vandees.

The species are all epiphytal, and bear solitary flowers on erect scapes; the sepals are nearly equal, forming a tube below and spreading above. The petals of *T. obtusum* are very small, almost hidden within the tube, and the labellum is even still smaller. It is easily cultivated in a warm house, and several plants in a pot make an attractive specimen.—L. K.

VICTORIA PARK.

SITUATED as it is in a neighbourhood densely populated by the industrial classes, this Park serves an important purpose, and serves it admirably, of affording wholesome means of exercise and recreation to those to whom such provision is especially beneficial, and, which is particularly gratifying, is warmly appreciated. None of the metropolitan parks are more thoroughly enjoyed than this is, and none are more worthy of the patronage that is bestowed on it by the many thousands of visitors who seek repose in its shady walks, take exercise on its ample lakes, and derive salutary gratification from its brilliant flowers. Owing to the extent and excellence of the floral decorations in past years Victoria Park has won much more than local fame—fame which has increased yearly, and which is splendidly sustained in the display of the present season. Those who delight in witnessing examples of floral decoration in various aspects—old-fashioned mixed border ornamentation savouring of the taste of the past, middle-aged lawn embellishment as exemplified in the Geranium-massing period, and modern artistic decoration embodied in semi-tropical masses and geometrical carpet beds—can enjoy all these modes, and the best examples of each, in this attractive Park. The skilful Superintendent of Victoria Park, Mr. McIntyre, takes a broad and comprehensive view of the subject of garden ornamentation. He is alive to the fact that the British public, for whose benefit the public parks were established, have varied tastes, and have a habit of closely examining and keenly criticising their floral fare, and hence he provides accordingly, and the provision is varied and excellent. He has no sympathy with those who denounce any one style of garden decoration, but, on the contrary, believes that each system is worthy of his best efforts. The mixed border has its own charms and its appropriate position, and so with floral masses and carpet beds. He is right. Does anyone doubt it? Remove, then, in fancy, for it is not likely to be so in fact, any one of these features from the Park, and the blank created will settle the point.

The beauty of the flowers in this Park is greatly enhanced by their setting—the handsome evergreens, especially Hollies, and the rich greenery of the deciduous trees and shrubs. These form a background and a foil which contribute in a powerful manner to the general effect. Take the small division, for instance, known as the West Park. The flowers are bright and beautiful unquestionably, but this portion would not be nearly so attractive were it not for the grand pyramids of Hollies. These, judiciously disposed, relieve what would otherwise be a tiring monotony of colour. A large circular raised mound in this division of the Park is especially noteworthy. It is surmounted with fine cones of variegated Hollies, literally in a “ring fence”—namely, a dwarf hedge of Aucubas. From the hedge to the walk the ground slopes sharply, and is effectively planted with flowers in concentric rings, festoons, and diamonds of contrasting colours, such as *Coleuses*, *Centaureas*, *Geraniums*, *Golden Feather*, &c., edged with *Echeverias*. This fine group is near the south-west entrance of the Park, and worthily commands much notice from the visitors. But bold as it is, it is only a trifle—an appetiser of the feast to follow. Turning one's back on this first instalment we find the mixed border stretching away on the left, a broad fringe to the belt of trees and shrubs which mark the western boundary of the park. This flower border is 7 or 8 feet wide and nearly a mile long. The order of planting, to speak paradoxically, consists in its irregularity. In this border there is always something to attract. In the early spring the bulbs which have been planted freely contribute their meed of beauty. A fine collection of Irises follow with clumps of spring flowers, notably the Iberises. *I. corifolia* is represented by large dense semi-globular plants, which in the early summer are masses of purity. This, one of the finest of hardy border plants, is planted alternately and at intervals of a few yards with earlier-flowering sorts, such as *I. sempervirens* and others. Then there are Pinks, sweet common Pinks, by hundreds, with the contrasting blue of stately Delphiniums. Campanulas, Antirrhinums, Phloxes, Foxgloves, Lilies, annuals, &c., contribute

their share of beauty during the summer, and in the autumn the *Helianthus*es, *Dahlias*, *Michaelmas Daisies*, and *Tritomas* are the principal “back plants,” and fine they are, with *Gladioluses*, *China Asters*, &c., in front. Between the border and the broad walk is a stretch of well-kept lawn containing flower beds at intervals filled with *Geraniums*, *Verbenas*, *Calceolarias*, &c., and the effect of one style of decoration increases that of the other. In these isolated beds the newer varieties of *Geraniums* are grown, and such of them as prove worthy are afterwards honoured by a place in the chief flower garden.

This is in the next division of the Park, and passing by several beds of *Yuccas* (how splendidly *Y. recurva* flourishes here!) it is soon reached. It is on the opposite side of the walk, and is in a large recess—that is, the lawn containing the flower beds has a bold crescent-shaped background of trees and shrubs. Between the flowers and the shrubs further relief is afforded by some fine specimens of American *Aloes* in tubs. The flower beds are large, and are uniform and simple in outline—circles of about 10 feet in diameter, and oblongs of the same width and from 20 to 40 feet long between the circles. The front row of beds next the broad walk are carpet beds and are strikingly beautiful, the remaining beds—the oblongs—being chiefly planted with *Geraniums*, with one or two in the back circular line of *Ageratum mexicanum*. The round beds are nearly all planted with *Coleus Verschaffelti*—beds which for perfectness of outline and richness of colour have never been surpassed. Good and well-worked soil, free healthy plants, and very close planting have produced these fine beds. They are edged with such contrasting colours as *Gnaphalium lanatum*, variegated *Geraniums*, *Golden Stellaria*, and dwarf *Lobelias*. The *Golden Chickweed* is in splendid colour, much brighter than the *Golden Feather*. It has been stated that before *Geraniums* are admitted into this garden they must have given proof of their satisfying qualities as bedders. They are tested simply on their merits. An old sort is not despised because it is old, nor over-estimated because it is new. It must be good, have upright trusses, free, level, distinct, and continuous, and then it matters not from whence it came or at what date it was introduced, it has a place of honour in this design, where nothing must be left to chance, but every bed must be as perfect as it is possible to produce it. Note now the few *Geraniums* that come up to the high standard required. As a strong grower for large back beds *Lucius* is unsurpassed; as a medium grower of glowing crimson colour *Waltham Seedling* is pre-eminent; while another of Mr. Paul's varieties (*Nimrod*) makes the best orange-scarlet beds; and as a pure dwarf scarlet *Vesuvius* bears the palm. The best of all the pinks is *Cleopatra*, but *Christine* is also not yet discarded, and the best salmon is the old *Madame Rudersdorff*. The beds of the sorts named are simply grand, and to all appearance will continue so for some time, while those of some of the newer sorts with larger trusses, produced more or less “side-ways,” have been injured beyond recovery by the late rains. The scarlet beds are chiefly banded with silver-variegated *Geraniums*, and edged with *Lobelias*; and the pinks with soft yellow-leaved *Geraniums* and silver *Gnaphaliums*. There are a few light beds, one for instance of the old friend *Flower of the Day*; but *Princess Alexandra* is perhaps the best bedder in this section, and as an edging plant none surpass *Flower of Spring*. These *Geraniums*, associated with such plants as *Iresine Lindenii*, which is extensively and well grown here, afford an agreeable change to the higher colours. The best yellow edging *Geranium* is *Robert Fish*. *Creed's Seedling* is also good, and *Crystal Palace Gem* makes an agreeable bed. The edgings of *Lobelias* here demand special notice. *Blue Stone* is dark and fairly compact, but *L. pumila grandiflora* surpasses all others by its close cushion-like growth and its wonderful profusion of bright blue flowers. These edgings can only be expressed in one word—excellent. One large bed of singular form in the centre of the group is distinct from the others; it is much raised and is very conspicuous. It is a long scroll-like bed with bold triangular spurs. In the centre of each wing is a triangle of Mrs. Pollock *Geranium* followed in order with broad bands of *Coleus*, silver-variegated *Geranium*, *Iresine Lindenii*, *Robert Fish Geranium*, and two rows of *Echeveria secunda glauca*—an arrangement which is strikingly effective.

There remain yet the carpet beds to be noticed. What can be said about them? An “inner voice” whispers, “Let them alone”—prudent advice which one would gladly follow were it possible that all who are interested could visit the beds and see for themselves; but they cannot, and yet they would like

some idea of their nature. The beds are in duplicate—some round, others oblong. They are all carpeted with the smooth green *Mentha* (*M. Pulegium gibraltaria*). How suddenly popular has this plant become! How marvellous has been its increase! No plant, not even Golden Feather, established its position as a general favourite more quickly. But what beside the *Mentha*? Let just one bed be noticed as an example, an oblong bed 20 feet long by about 12 feet wide. The carpet of this square is *Mentha*. From the centre of the bed rises another bed about 4 or 5 feet long and 3 wide; it is distinctly above the *Mentha* level. The sides—the batter—being planted with two tiers of *Echeveria secunda* glauca, with an inner row, just on the level, of the green *Sempervivum arvense*. The surface of the bed is divided into longitudinal panels with curved lines of *Echeverias*, the interpaces being filled with *Alternantheras*. In the centre is a plant of *Sempervivum tabulaforme* in a narrow ring of Golden Feather. At each end of the raised square and at proper distances from it are two round beds raised above the *Mentha* in the same manner. They are 3 feet in diameter. The edges and centres are the same as in the square elevation. In the body of each centre is formed a star, the rays being of *Echeverias* and narrow wire-like lines of Golden Feather, the interpaces being filled with *Alternantheras* in brilliant colour, with a single plant of *Pachyphyton* in each spur. The effect is rich yet chaste. The other beds are of the same character, but with a different and well-wrought-out geometrical pattern in the carpet of *Mentha*. The narrow golden streaks of *Pyrethrum* in these beds have a cheerful effect. "Don't like yellow in carpet beds," does someone mutter? Well, others do, and even those who do not are provided for: for leave this brilliant example of flower gardening and follow a twisting walk between the shrubs, stealing a glimpse in passing through the vistas and admiring the scenery beyond—richly clad mounds of foliage, smooth dells, and glistening water scenes, and you arrive at another group of beds with not a flower in them, and no yellow foliage. Here note the luxuriance of the "tropicals"—the *Wigandias*, *Cannas*, *Indiarubbers*, *Loquats*, &c., and the Fern-like masses of *Acacia lophantha*. Look at the quiet carpet bed at your feet—no colour there, all is neutral. The carpet is of *Sedum glaucum* dotted with *Cactuses*, *Haworthias*, *Gasterias*, and dwarf *Aloes*. Does that please? "Too tame" is it, Mr. Hypercrite? Well, pass on, there is much to admire *en route*—the trees, the shrubs, and the "peeps" between them, and yet another series of carpet beds compels a pause. The beds are nearly all round, and all are planted differently, some soft, some gay, but all beautiful. Describe them. No, an emphatic no. Go and see them and—find fault. Look at the central bed—the scroll. It is called the "jewel bed"—a happy name, for the small bright designs and single plants at wide intervals in the broad green expanse of *Mentha* render the name appropriate.

No doubt many turn from these beds with a feeling of disappointment. Why? Because they cannot produce the like at home; and why not? Let Mr. McIntyre answer. He has been a successful gentleman's gardener, and now he is a successful Government park superintendent, but he admits readily and willingly that as a private gardener he could not achieve such high-class decorative results. In a gentleman's garden a hundred things require attention; the resources are divided, and decoration and bedding can only have its share. Here in the Park it is the one object, and all the resources, all the conveniences, all the skill are devoted to that object, hence success. It is only fair to mention this. Yet let all visit the parks of London who can do so, for they will gain from them many a hint that will serve them well in their home duties.

Much more in Victoria Park deserves to be noticed—many excellent isolated beds. In one the new dark green carpet plant *Herniaria glabra*, or rather an old plant devoted to a new purpose. It is hardy, close-growing, and a rich full green. The rockery so varied with alpine gems, *Cactuses*, *Aloes*, *Hydrangeas*, *Palms*, and *Monstera*s; the groves and avenues all merit inspection and approval, but the mere recording of them must now suffice.

The whole of the plants employed are raised and wintered in small houses in the Park. In the summer the houses are occupied with ornamental-foliaged plants, such as *Caladiums*, *Coluseas*, &c., with the laudable object of decorating the rooms and tents in which the thrifty inhabitants of the district hold their little exhibitions of window plants and florist flowers. The *Coluseas* after serving their purpose are destroyed, and the *Caladiums* are placed under the stages, so that they do not

occupy useful space during the winter. Mr. McIntyre takes great pleasure in thus aiding his neighbours, and he speaks approvingly of the prudential habits of many of the industrial classes at the "east end," adducing as proof the following fact which is highly worthy of being recorded. Near the Park is a noble hospital for diseases of the chest, supported by voluntary contributions. In order to support this institution, and at the same time to command its benefit, workmen's clubs are established in the locality, the members of which contribute their pence weekly until sufficient accumulates to purchase a life governorship. The members then ballot for the purpose of deciding who shall represent them as life governor. It is a most commendable system, and an honour to the district of Bethnal Green. Bethnal Green is really a "green" now and something more. Formerly a waste, a receptacle for broken pots and refuse, it is now an attractive square with lawns, walks, and flower beds. It was levelled, laid out, and planted by Mr. McIntyre, who has done his work admirably. The shrubs and trees are growing freely, although a smoky mist hangs over them almost daily, and a spacious and ornamental pleasure ground is now established.

Victoria Park is highly worthy of a visit by all who are desirous of seeing effective and artistic flower garden decoration, and an inspection of the beds will repay for even a very long journey. It is best reached by rail from the Liverpool Street station, booking to Cambridge Heath. Many err by going from Broad Street to the Victoria Park station, which is a long distance from the flower beds.

The Superintendent of this Park, like most able men, can afford to be generous, and he is desirous that the experienced head gardener at the Park, Mr. Bullen, should have his full share of the credit which is due to him for the manner in which the decorations are carried out.—J. W.

NEW ROSES.

I SELDOM buy these on weak stocks, as my situation is so exposed and unsuitable for infants. The best that I have seen lately are Queen of Waltham and the Star of Waltham. They are very good and specially suitable for exhibiting. They are on weak stocks, and have done wonderfully well for plants on weak stocks. I have ordered six of each on strong Manetti stocks to be reserved for me in the autumn, which I should not have done had they not been worthy. Till Roses are put on strong and suitable stocks and are established in the soil we cannot tell their full merits. It strikes me that new Roses are often written "up" or written "down"—according to fancy, or favouritism, or non-favouritism—before they have emerged from the weakness of infancy. Some raisers cannot do right, and some cannot do wrong.—W. F. RADCLIFFE.

NOTES AND GLEANINGS.

MR. NATHAN COLE has received the following letter from Balmoral, dated August 25th, 1877:—"Major-General Ponsonby is commanded by the Queen to thank Mr. N. Cole for the copy of his work on the 'Royal Parks and Gardens of London' which he has presented to Her Majesty."

—ACCOUNTS continue to reach us from various districts on the great virulence of the POTATO DISEASE. We can offer no better means of limiting the injury than by spreading the tubers very thinly in sheds and covering them with dry sand, to exclude the air and absorb the moisture. A correspondent suggests dusting them with lime—an experiment which may be easily tried, which cannot do harm and may do good. Potatoes which are infected are better left in the ground for a time until the weather is cooler, than being taken up and stored thickly in heaps, where they often heat rapidly and decay speedily.

—MUCH damage has been done in various districts by recent STORMS and FLOODS. A Lancashire correspondent writes that "flower gardens are despoiled of their beauty and the plants are seriously broken and injured. In the low-lying districts gardens have been flooded, and many acres of Potatoes and other crops have been under water." In the south showers have been frequent, and the flowers in the London parks have lost their brilliancy. The carpet beds, however, look as bright as ever. The Potato disease is spreading, green crops growing, and weeds where undisturbed are making considerable progress.

—MR. MOWBRAY, gardener to the Earl of Leven and

Melville, informs us that his neighbour Mr. Wood, gardener to Sir Erskine Perry of Fulmer, near Slough, has upwards of fifty flowers on one stem of *LILIUM AURATUM*, the plant being grown in an 8-inch pot. The plan of culture adopted by Mr. Wood is to shake out the plants, removing all the soil from the roots, immediately the flowers fade, and repot in fresh compost—loam, leaf soil, and sand, and place out of doors. The plants are buried in ashes out of doors, and there pass the winter. We shall be glad to hear more precise particulars respecting these plants and Mr. Wood's successful mode of growing them.

— OUR readers will be glad to learn that the success of the CARLISLE INTERNATIONAL EXHIBITION is now rendered certain by the large number of entries and the completeness of the arrangements made by an energetic Committee. The preparations are nearly finished and the show-ground enclosed, and the erection of the marquees has commenced. Horticultural buildings and many miscellaneous articles have also begun to occupy the space allotted to them. The weather, too, has fortunately improved, and everything looks favourable for the Exhibition next week, which will be a great success if the bright days continue. The large premiums offered by the Committee have attracted a great number of competitors, and exhibitors are daily applying for space. The general attractions of the Show will be numerous and varied, and not the least will be the presence of the splendid band of the 2nd Life Guards in uniform during the three days, under the leadership of Mr. Winterbottom. The Judges' dinner will be presided over by the Lord-Lieutenant of Cumberland, Lord Muncester, the Mayor of Carlisle being Vice-Chairman, and will be attended by a distinguished company, including the ladies who will honour this Exhibition by acting as Judges of the bouquets and cut flowers.

— WE are requested to state, that in consequence of the Great International Show at Carlisle being held next week, the usual monthly meeting and dinner of the HORTICULTURAL CLUB will be held on September 18th, instead of September 4th.

— WE have received from Mr. Moorman a sample of the SNOWFLAKE POTATO, asking our opinion of them. It is as follows:—More attractive-looking Potatoes were never grown. The tubers are of the right size for table and contain few eyes, and these small and indistinct, involving a minimum of waste in paring. When cooked the Potatoes are almost as white as snow and are extremely delicate in flavour. They are not like the proverbial "balls of flour," but are sufficiently mealy for many palates. Not a speck of disease was found on the tubers. As Snowflake is productive it must be pronounced an excellent second-early variety for table use, and its handsome appearance renders it indispensable for exhibition purposes.

— THE DAHLIA QUARTER in Mr. Turner's nursery at Slough is now highly worthy of inspection. Although late, the show varieties are producing some grand blooms, and the bouquet and bedding varieties are in splendid condition. Yellow Pet amongst the bedders is especially fine, but all are good and eminently worthy of culture for producing a rich and varied effect during the late summer and autumn months. The Carnations are nearly all layered—a splendid and unrivalled stock, and the winter-flowering varieties are remarkable by their health and numbers. Chrysanthemums appear to be receiving special attention, and a grand and novel display may be anticipated. The standard plants are unusually fine, the grafted heads being as healthy as those not grafted. The plants were kept close for a week or two when the grafts were put on, but they are now growing in the open air, the unions being complete. The huge Roses in pots are under glass; they have made excellent growth, and will shortly be placed in the open air for a week or two. Camellias, Azaleas, and Oranges are in admirable condition. The Camellias are placed continental fashion—between close rows of Lombardy Poplars, where they have shade without drip. Liliiums, especially *L. auratum*, are remarkably fine. Roses are flowering with great freedom, but some not flowering are particularly noteworthy—plants in pots of *Maréchal Niel* for roof-decoration, this season's growth of which is wonderful. The carpet and other bedding render this nursery additionally attractive during the summer; but the great feature during the next six weeks will be the Dahlias above noticed.

— AN effort is being made by the inhabitants in the neighbourhood of Kew to have the gardens opened at an earlier hour than one o'clock, also to prevent the wall which surrounds the gardens being raised beyond its present height. It will be

desirable to open the gardens earlier, particularly on special occasions, such as bank holidays, if that can be done consistently with securing their efficient management. The changes which are being sought for, and apparently in a reasonable manner, are worthy of much consideration on the part of the authorities.

— MR. W. TAYLOR writes to us that POTATOES ARE WORSE DISEASED at Longleat than they have been for many years. Ashleaf and Myatt's Prolific were taken up early in July before the last-named sort was fully grown, as the disease was already very threatening. Not a tuber of these has taken the disease, and all are perfectly sound excepting where the skin was broken by rough handling, and these have shrivelled somewhat. They require very careful handling when taken up early. Fortyfolds, Dalmahoy's, Regents, and other second earlies were too small to be of any use when the disease appeared. In the light soils the disease does not appear to be quite so bad as it is in heavy soils.

— A CARLISLE correspondent writes that visitors to the great Show will find much to attract in the admirably-kept nursery of Messrs. Little & Ballantyne; also in the nurseries of Messrs. Clarke, Brothers, Stanwix; Messrs. J. Hamilton and Sons, Messrs. Joseph Hamilton & Son, Mr. Armstrong, Belah Gardens, &c. There are many fine gardens belonging to noblemen and gentlemen within short distances of Carlisle worthy of a visit, and visitors will be freely welcomed at them all during the International Show. Our correspondent especially recommends a visit to Lowther Castle, the seat of the Earl of Lonsdale; Brougham Hall, Lord Brougham; Eden Hall, Sir R. C. Musgrave, Bart.; Corby Castle and the lovely scenery of Corby woods, Philip Howard, Esq.; Naworth Castle, the Earl of Carlisle; Rickerby House, Miles MacInnes, Esq.; Netherby, Sir F. U. Graham, Bart.; and last, though not least, the unequalled beauties of Drumlanrig Castle, the seat of his Grace the Duke of Buccleuch: these are within easy distance of Carlisle, and can be reached by rail or road.

NOTES FROM CORNISH GARDENS.

LAMORRAN.

In a quiet secluded valley, amidst steep hilly wooded slopes in a cosy nook at the head of the waters of Lamorran Creek, away from the beaten track of the busy world's highway, is the residence of the Hon. and Rev. J. T. Boscawen, well known to men of science and horticulturists as a wise counsellor and friend, who, although thus living apparently apart from the world, is one of its most busy workers, ever ready to aid in promoting those arts which he loves and understands so well, and who has turned the very quietness and seclusion of his home to good account by solving many a horticultural problem, evolving lessons of such value by the wonderful results obtained in his garden that I can think of no more fitting title for it than that of a book written by the hand of a master, every page of which contains lessons as novel as they are useful.

It has very lately been my privilege to enjoy the hospitality of Mr. Boscawen—to see his garden, to study the lessons which it teaches, and in some measure to grasp their meaning, sufficiently so I hope to enable me to explain their full significance, and to show how what is really a great and pioneer work may be accomplished within small bounds and without many of those facilities which by many gardeners are considered indispensable to success. It was not long ago that I strongly enforced the importance of planting objects of interest in gardens. At Lamorran this principle was long ago understood and acted upon, and the result in this sense is a garden so abounding in plants and trees that are alike so varied and beautiful as to positively embarrass one. It is a veritable storehouse of treasures rich and rare, so skillfully cultivated and arranged in such good taste as to be always fresh and always attractive.

When Lamorran House was built upon a narrow plateau upon the face of and near the foot of a steep slope Mr. Boscawen had to make immediate provision for screening both it and the garden, which he contemplated making, from the scathing blasts which so frequently rush in from the mighty Atlantic over every part of Cornwall. Dense wild woods clothed the slopes and shut in the valley above the house; but below it was the bare expanse of water, a gradually widening valley with trees on the hillsides beyond the water, but with its own particular slope almost bare of trees. What was to be done? Throw up a barrier and plant sturdy fast-growing trees across the valley down to the very edge of the water? Expediency might suggest such a course, but correct taste never would

agree to it, for the work would clash with every line and curve of nature. The difficulty was overcome skilfully and well by making tree-clothed banks from the natural slope at an irregular acute angle up the valley, so as to offer the least amount of resistance to the wind while it turned it away past the garden completely. The natural appearance of these screens, the perfect shelter which they afford, and their entire harmony with the position and its surroundings, form a valuable study, and convey a lesson in landscape gardening of the utmost value, so intimately do they combine the ornamental and useful.

The site of the garden itself is a long steep hillside, or rather a series of irregular grassy slopes, stretching from a point high up the valley's lofty side downwards to a road skirting the margin of the water. It is traversed by walks winding along and up the banks in picturesque irregularity among shrub groups consisting principally of *Rhododendrons* and *Azaleas*,

in perfect health and very vigorous growth, mingled with other rare and choice shrubs and a pleasing variety of Conifers and deciduous trees—trees planted by Mr. Boscawen, and now become so large as to really merit the appellation of fine. The pleasure with which one regards the trees arises from the skilful way in which they are arranged and are made to blend and become merged with the wild growth of the wood beyond, up to which they lead, as well as from the elegant and stately appearance which most of them present individually.

The most conspicuous trees are a number of magnificent examples of *Pinus insignis*. This tree as seen here is certainly worthy of its title of "the Remarkable Pine." All are in perfect health, and some are wonderfully vigorous, being 80 feet high, with huge rugged stems feathered with branches to the ground, clothed with foliage of that bright rich green tint which makes this tree so striking, and for which it is so

Fig. 40.—LAMORRAN.

much valued. It makes a splendid tree, and judging from what subsequently came under my notice during my tour in Cornwall I have no hesitation in saying that it is quite the best Pine for that county. It bears exposure perfectly, it becomes established quickly, grows with singular rapidity, and its timber is really valuable, some boards of it which Mr. Boscawen had nailed upon the gable of a building twelve years ago and there left fully exposed without any covering of paint being still perfectly sound and free from any traces of decay.

Several other Conifers must have notice, and first most worthily comes a noble specimen of *Sequoia sempervirens*, the Californian Redwood tree, to which a very picturesque effect has been imparted by cutting off the lower branches so as to show the curious bright red spongy bark, so soft as to yield to the slightest touch. *Picea cephalonica* is well represented by some excellent specimens; it is one of our best Conifers, superior to *P. pinsapo*, but unfortunately not quite so hardy in many situations. *Cupressus Lambertiana*, *Thuja Lobbi*, the rough-barked Mexican Pine, *Pinus Montezumae*, *Pinus maritima*, and *Cedrus atlantica* are all growing into fine specimens here, *Cedrus atlantica* being especially remarkable for its strong free growth and perfect health, offering a striking contrast to the stunted sickly appearance of the *Deodar*, which is evidently not happy here. I was glad to see *Picea Webbiana* in excellent condition and evidently full of growth, but it is

questionable whether it will attain to a very large size, as it is already producing cones. Among other rare Conifers is a beautiful specimen of *Fitzroya patagonica* 10 feet high, a perfect gem, with graceful pendulous growth, forming an object of great beauty; and, wonderful to tell, there is actually a flourishing specimen of *Dacrydium Franklii* here, surpassing all other weeping trees in the elegance of its long, graceful, pendant branches. It is curious to see how quickly even the leading branches conform to the general character of the whole tree, for after a very brief growth upwards down they go, falling over each other in no regular order, but with an easy careless air full of grace, to which the somewhat loose clothing of leafage adds another charm. The position of this *Dacrydium* undoubtedly contributes something to its effect; and I may usefully note here how much more telling pendant-growing trees are when planted on slopes above a walk than when seen on a plateau or level lawn. They are, moreover, equally effective upon soft gentle slopes and steep rocky declivities; while, on the contrary, trees of such precise growth and rigid aspect as the *Araucaria* are not in keeping with soft lines and sweeping curves, but require scenery of bolder, wilder, sterner aspect.

First among other varieties comes the Palm, a magnificent specimen of *Chamærops Fortunei* 16 feet 4 inches in height—a tree of stately aspect most pleasant to the sight, for it is

without a single blemish; the huge green foliage presenting a striking contrast to the battered, lacerated, forlorn, decaying aspect under which this Palm is too often seen when grown in tubs and afforded the shelter of a conservatory in winter. I believe this to be by far the finest specimen established in the open air in this country. It stands low down on the Lamorran slopes, well sheltered but yet growing alone on a little eminence close by the gigantic Sequoia with its huge red bole and lofty symmetrical growth, affording a striking contrast, and forming a worthy associate to it, although so totally diverse in character. There are other smaller Palms upon different parts of the slopes, all of them in good health and evidently growing freely.

Andromeda formosa grows here into huge shrubs 6 feet high. *Erica codonodes* is also perfectly wonderful, having the proportions and air of a shrub. Many specimens of it which

fringe a broad walk at intervals are apparently fully 10 feet high; they grow upon the side of a steep bank with the lower branches spreading downwards to its foot, and the top one clusters upwards erect and plume-like. A fine specimen of *Olea ilicifolia* 8 feet high proves perfectly hardy, having passed unscathed through frosts which have cut off Bays to the ground. *Aralia japonica* (Sieboldi) is so large that its handsome foliage has a fine effect as seen in contrast with that of surrounding trees. A flourishing tree of the Glastonbury Thorn, raised from a graft taken from the original plant at Glastonbury the year before it died, is a great curiosity, as it never fails to have flowers open on Christmas day. In appearance it is identical with the common Thorn.

Rhododendrons and Azaleas are to be seen in every part of the grounds; the whole of them are choice kinds, and many of the Rhododendrons are so rare as to be quite in keeping with

Fig. 41.—LAMORRAN—VIEW IN THE GROUNDS.

the other treasures of this wonderful garden. Himalayan kinds, such as *arboreum*, *arboreum niveum*, and *arboreum cinnamomeum*, prove perfectly hardy here. The flowers of these, with many other choice species and varieties, have for years been subjected to such careful and skilful manipulation that the place abounds with seedlings raised here by Mr. Boscawen, who began this highly important work with a stock of some 140 sorts about twenty-six years ago. The majority of the kinds so raised prove very early; so much so that the first flowers are often cut off soon after they expand, to be quickly succeeded by others which are not unfrequently also destroyed prematurely. The wood-growth and foliage are so hardy that Mr. Boscawen considers them most worthy of cultivation in every garden where a spare glass house could be had to protect them when in flower; for the flowers are so lovely, ranging through such charming gradations of colour, as to well repay for the work of lifting them and planting temporarily under shelter for the flowering season. That the plan is practical there can be no doubt, for we have no shrub that bears removal so well as the Rhododendron.

The consummate taste displayed in the grouping and blending of various trees and shrubs here affords a valuable lesson. Deciduous trees and Conifers are alike well chosen and well placed, and in no garden that I have ever seen can we so well appreciate the full value and beauty of the Tulip Tree, Birch,

Acacia, Scarlet Oak, Lime, Butter Nut (*Juglans cinerea*), *Arbutus*, Sugar Maple (*Acer saccharinum*), and Copper Beech, every one of which affords relief and harmonious contrast to the somewhat formal aspect of the Conifers. This is a matter not nearly so well understood as it ought to be, and is so important as to merit special attention, hence I propose to refer to the subject on a future occasion.

So many objects of interest occur at every turn in this garden, and all are so good, that we hardly know what to select and what to leave unmentioned. Virginian Creepers climb the stems and festoon the branches of lofty trees, to blend their brilliant crimson autumnal tints with the various yellow shades of the trees to which they cling. Lilies abound here. *L. giganteum* has spikes more than 10 feet high, and it has sometimes exceeded 12 feet. *L. auratum*, of course, finds a home here. There are numerous fine spikes of it, some with flowers just expanding, others will be much later. Many of them are planted singly in irregular semicircles of Rhododendrons by the margin of the paths, which thus afford shelter, while the deep green foliage forms a charming foil to the delicate tints of the flowers. *Lilium martagon* was in full bloom; its flowers though small are very striking from their brilliant rich scarlet colour. Rhododendron *Thompsoni* is wonderfully vigorous. *Lapageria rosea* is thoroughly established on the house (fig. 40), to the right of the principal entrance;

it is some 20 feet high, is growing most strongly, and has a considerable number of flower buds which, strange to say, all spring from the old branches. One flower was just expanding, and others will follow for some time to come.

In spring time and early summer, Crocus, Snowdrops, Narcissus, Scilla, and a host of other spring beauties which have their bulbs permanently established deep down beneath the turf out of reach of the mice, push their growth through it by thousands, bursting into flower a myriad of vernal gems, which thus change the grassy slopes into one vast flower garden—an easy and delightful method of spring gardening which will commend itself to everyone, for who would not like to see their lawns under such a novel and charming aspect? Nor is the treat confined solely to spring, for under the branches of the Conifers and such shrubs as appear suitable there are Cyclamens of all sorts, Atkinsi, persicum, Coum, and hederacifolium in all their varieties, with europæum, repandum, ibericum, vernum, and macrophyllum. Under the Pinus insignis there are whole beds of them covered by the old Pine needles, which are never removed but are left to gradually form a tawny carpet, through which the pretty flowers push their way all through the winter months. I like this plan of leaving the old Pine needles; the effect is picturesque, natural, and certainly not untidy.

A new feature here is an adit which has been driven through the shale of an upper slope. Along its sides are various nooks and corners—just so many snug little homes for rarities, of which there is already a goodly store. On these, however, I must not dwell; nor must I do more than call attention to the numerous panfuls and beds of seedlings of shrubs and flowers, every one of which may fairly be expected to prove "something fresh," for they are all raised from seed resulting from the cross-breeding and hybridising which Mr. Boscawen is constantly carrying on. I am tempted to dwell upon these, but space forbids. A closing paragraph on the romantic scenery of Lamorran must conclude my notes on this remarkable garden.

Lamorran is like a poet's dream—always beautiful, yet ever changing and presenting some new charm to the fascinated eye. The long graceful sweep of the valley; the bright glistening waters stretching far away, cool and still, yet abounding with life; the lofty hillside clothed down to the water's edge with a dense growth of trees, the tops of which mark the flowing undulations of the slopes like the billows of the sea; the pretty church standing amidst the graves of those who worshipped within its walls long ago close by the water's edge, reminding one of those romantic old kirkyards still to be found on the margin of many a Scottish loch; the house in the very heart of the valley, deep down yet commanding its most pleasing features, all combine to form a scene of romantic beauty such as mere description can convey but a very faint idea of, but which is in a good measure represented by the accompanying engraving (fig. 41). On the last morning of my visit, a bright and sunny day, the picture from the terrace was perfect. There was a charming play of light and shade among the trees which cast their shadows far out on the quiet waters of the creek, where the eye rested on a foreground of a large patch of Water Lily, past which swam slowly a white swan and her train of dusky cygnets. Wild ducks too were there, tamed for the moment under the influence of the quietness around them. A fringe of Fern, mingled with pendant branches of Mountain Ash laden with bright scarlet berries along the water's edge; while high overhead sailed white fleecy clouds, chequering the deep blue of the sky.

I am requested by Mr. Boscawen to invite any lover of nature to call and see this charming valley and its garden; and I have no doubt that those whom these notes may induce to do so will agree with me that it is most beautiful—replete with varied charms, and the very embodiment of repose.—EDWARD LUCKHURST.

ROMNEYA COULTERI AT GLASNEVIN.—The *Irish Farmers' Gazette* describes a specimen of this which was only struck from a cutting in the spring of last year and is now some 6 feet high, 4 or more through, and every branch and branchlet terminated by a flower or flower bud. The expanded flower is fully 6 inches across, quite flat, delicate in texture, and pure white in colour; from the centre rises a great ball of gold, formed by the close globular aggregation of anthers innumerable, forming with the petals a brilliant and beautiful contrast of white and gold. The protection afforded the plant during the past winter

was of the most trivial kind, and it is doubtful if even this was absolutely necessary; a slight protection over the roots we apprehend being all really required, perhaps not even that. The present cold, sunless, and weeping summer was by no means best calculated to bring out its grand flowers in the quality and profusion seen under Californian light and sunshine. Nevertheless here we have it now blooming freely and profusely for some weeks, and likely to continue to do so for weeks to come. In its regard, therefore, three things are, we think, very fairly established—firstly, its perennial character; secondly, its hardihood; and thirdly, its early flowering and very striking and highly ornamental aspect.

TAKING-UP POTATOES.

I CAN testify to the soundness of Mr. Luckhurst's and "NORTHERN GARDENER'S" remarks on early lifting of the Potato crop, or the pulling-up of the haulms (not cutting, as it only partially arrests the disease). But here in Dorset we seem to be in the same predicament as "NORTHERN GARDENER;" the murrain has destroyed one-half the crop before the main crop Potatoes have ceased swelling.

We have just lifted (August 22nd) a piece of Paterson's Victoria Potato, where the haulm was pulled away the 28th of July, and we have a fair crop and next to none diseased, but adjoining the same sort with the same treatment (excepting the tops being taken away) one-half are diseased.

We had a plot planted with Snowflake Potato, and as the time could not be spared the haulm was pulled away, and now they are just lifted, all good-sized tubers, about three bushels per perch, none diseased.

Removing the haulm is thought by many cottagers to be useless, but in every case I have found they delayed doing it till the stalks were much affected. I find it best to leave the Potatoes in the ground for two or three weeks after the tops are drawn away, if a convenient place cannot be found to dry and ripen them before storing.—A. P.

ROYAL HORTICULTURAL SOCIETY.

AUGUST 24TH.

FRUIT COMMITTEE.—Henry Webb, Esq., V.P., in the chair. The meeting was held at the Society's Garden, Chiswick. The collection of Tomatoes, which have been grown in pots under glass, were first examined. The collection is represented by over sixty differently named varieties, two plants of each being grown. These the Committee had arranged into classes as distinct in appearance, and amounting in all to thirty-one, which number may, however, be still further reduced or increased when further examined in comparison with those growing in the open air. These Tomatoes at the present time are most interesting and well worthy of inspection. The smallest variety is represented by Red Currant, of about the same size as a Currant; the largest variety is The Trophy; the earliest is The Early Gem, and the latest De Laye's, which is of little value.

First class certificates were awarded to Little Gem (Bliss), a medium-sized, round, deep red variety, very free-fruited and very early; to New Improved (Vick), a large smooth ovate variety of a distinct rosy crimson colour, free-fruited; to Vilmorin's Large Red (Vilmorin), a very large slightly-ribbed variety and a wonderful cropper; to Trophy (Carter & Co., Veitch, Wheeler), an exceeding large nearly smooth red variety, of fine appearance and late. Hathaway's Excelior was found to well merit the certificate that was awarded to it some time ago; also Green Gage (Carter), as being by far the best yellow variety. Conqueror, One Hundred Days, and Portsmouth amongst the new varieties were greatly admired.

The collection of cordon-trained Peaches and Nectarines on open wall were next examined. These trees, which have this season done good service, are in perfect health, and many of them are bearing heavy crops. Prominent amongst all others stands the Lord Napier Nectarine, which was awarded a first-class certificate. The fruit is very large, roundish oblate, of a deep dark purplish colour; the flesh is pale throughout, of rich and excellent flavour, having a dash of the Stanwick in it. It is of fine constitution and a free bearer.

Turnips were next examined. Of these a very extensive trial has been made. The earliest varieties were found to be the American Strap-leaf, White and Red-topped. This is an exceedingly fine Turnip, and completely takes the place of the old White Dutch, which seems to be almost worn out; at least, no true or good stocks of it have been grown here. Following these come the Early Red Top, the Red Globe, and the Early Six-weeks or Snowball, which has numerous synonyms. This is the main-crop garden Turnip, and the finest of all. Of other

varieties—all good enough in their season, but including no novelties—were noted a very good stock of the Long Vertus pointed-rooted, which comes in very early, and is much used in France, although not in this country; the Round Black or Chirk Castle, an excellent autumn sort; the Yellow Finland, Yellow Malta, Orange Jelly, &c. The whole of those dry-fleshed Turnips—as the Teltaner and others, so esteemed in some parts of the Continent—proved a failure, as well as many of the varieties generally grown for field culture. A later sowing of Turnips has been made which will be in due course examined. The collection of Savoy, it may be mentioned, are now nearly ready for inspection.

FLORAL COMMITTEE.—Mr. John Fraser in the chair. This meeting was held at Chiswick on August 27th. The Committee proceeded with the examination of the zonal Pelargoniums, of which there is a large collection planted out this season. Many of the sorts have suffered severely from the recent heavy rains, but the following varieties, being in excellent condition, were deemed worthy of first-class certificates—viz., Excelsior (Denny), scarlet, with distinct white eye; Charles Smith (Pearson), dark scarlet; Mrs. Huish (Pearson), magenta scarlet; Portia (Donny), magenta scarlet; Mabel Eden (Pearson), light magenta; Lais (Denny), magenta scarlet; Mrs. Holden (Pearson), rosy pink; Mrs. Lancaster (Pearson), rosy pink; Lord Giffard (George), bright scarlet. Among the older varieties Triomphe de Stella, Golden Harry Hieover, Vesta, Rose of Summer, Claude de la Meurthe, Arthur Pearson, Princess of Wales, Mrs. Turner, Christine, Cleopatra, Lady Emily, and Snowdon were conspicuous.

The collection of Pelargoniums, consisting of all the newer varieties which have this season been grown under glass, was then examined, and the following being considered very suitable for pot culture were awarded first-class certificates—viz., Miss Wakefield (Pearson), orange scarlet; Louis (Pearson), rosy purple; Lustrous (George), very bright scarlet; Lady Eva Campbell (Pearson), salmon; Mrs. Pearson (Pearson), bright orange scarlet. Among other varieties Thibse, Charles Smith, Miss Strachan, Lizzie Brooks, Rebecca, Blanche Gordon, and Lord Zetland were especially noticeable.

The double Pelargoniums, consisting of a selection of the best varieties of last season and new sorts received during the present year, were then examined, and first-class certificates awarded to the following—viz., Deputé Aneelon (Lemoine), deep magenta rose, and Le Nord Est, bright scarlet. Madame Thibaut, Noemie, O. Gligm, Auguste Villame, Meteor Flag, Mrs. Trevor Clarke, Madame Amilio Baltet were also very fine.

ASTERS.—A large collection of these now in full bloom was then examined, and the following were highly commended as being excellent stocks—viz., *Pomponne* (Dippe Bros.).—Of erect moderately bushy habit, producing very close compact heads of flower. *Diamond* (Haage & Schmidt).—This seems to be a larger and more vigorous-growing variety of the *Pomponne*. *Dwarf Chrysanthemum-flowered* (Dippe Bros.; Carter & Co.).—This is perhaps the best variety of any for general use, never exceeding 10 inches in height, and yielding in great profusion very large and well-formed flowers. *Victoria Asters*.—This to all appearance seems to be a tall-growing variety of the *Chrysanthemum-flowered*. *Betteridge's Exhibition Quilled*.—A very distinct and pleasing variety, throwing the flowers well up; and, being of a hardy constitution, does not seem to be affected by rough weather. A full report on these will appear in the Society's Journal.

DIANTHUSES.—Of these beautiful annuals a very large collection has this season been grown, and on examination the following received first-class certificates—viz., *Heddewigi hybridus flore-pleno* (Benary), *Heddewigi laciniatus* (Benary), *Hedewigi hybridus atro-purpureus* (Benary), *Chinensis flore-pleno* (Benary), *Imperialis flore-pleno* (Benary), *Heddewigi plenissimus splendens* (Haage & Schmidt), and *Heddewigi* (Benary).

SELECT APPLES AND PEARS FOR THE NORTH OF ENGLAND.

HAVING been requested by a correspondent ("S. S.") to name a few choice dessert and kitchen Apples, also Pears, that will grow in the north of England—the trees being required as bushes and pyramids in a moderate-sized garden—I gladly submit a few which I have found to succeed. As I have previously observed, I do not recommend planting just one tree of a sort so as to have a great number of varieties, but prefer to have duplicates of a few sorts which I find reliable, and which afford a good succession of fruit during an ordinarily good fruit year.

I will begin by naming a few good dessert Apples, placing them in the order of ripening. Summer—Margaret, Early Harvest, and Devonshire Quarrenden. Autumn—Oslin, King of the Pippins, Red Ingestrie, Ribston Pippin, and Cox's Orange Pippin. Winter and spring—Adams' Pearmain, Court

of Wick, Claygate Pearmain, Scarlet Nonpareil, Margil, Court-pendu-plat, and Sturmer Pippin. Kitchen—Lord Suffield, Stirling Castle, Cellini, Small's Admirable, Mère de Ménage, Cox's Pomona, Warner's King, Fearn's Pippin, Holland Pippin, Yorkshire Greening, Dumelow's Seeding, Norfolk Stone Pippin, and Gooseberry Apple. The above Apples are hardy, good growers, yet tolerably compact, and free bearers.

Pears—Citron des Carmes, Williams' Bon Chrétien, Beurré d'Amanlis, Louise Bonne of Jersey, Comte de Lamy, Beurré Diel, Zéphirin Grégoire, Ne plus Meuris, Beurré Sterckmans, Knight's Monarch, Joséphine de Malines, and Bergamotte Esperen. The sorts named will afford, if planted in duplicate, sufficient fruit for a moderate-sized garden, while one tree of a sort will form a good collection for a small garden. It is advisable when information on fruit trees is requested that the number of trees required be stated.—A NORTHERN GARDENER.

A COTTAGERS' SHOW.

"*De minimis non curat*," not "*lex*" to-day, but *lectores* of the Journal. "Then why, sir, do you write about such minute things? Do you suppose the readers of the Journal want to be bothered by an account of a wretched little cottagers' show, held, too, in the wilds of Dorset? Is there no end to your words, or will the winter's snows alone suffice to stiffen the hand that writes such a pack of rubbish as 'Whitchurch Cottage Gardeners' Show?'" Thus asks, perhaps, more than one angry reader as his eyes see the above heading. Turn the page, my dear sir; skip the letter, read the ornate and clever writings to be found in the Journal on Orchids and Grape culture, and don't, please, let your anger at this article interfere with your digestion. If, however, you do, am I to blame? Are a few lines upon a cottagers' show so very inappropriate that the sub-editor should tear up the manuscript?

In some letters that I have received from kind friends I read, "I observe in your letter in the —," What? Not *Journal of Horticulture*, or *Rose Journal*, but *Cottage Gardener*, and for many years I believe this Journal was called by that name, and many people still persist in calling it so. This being the case, why not write about a cottage gardeners' flower show?

In Whitchurch Canonieorum, in the county of Dorset (from which huge parish my own little one was carved, so that I may almost say in my own parish), exists a Cottage Gardeners' Horticultural Society, which I believe is most successful. It has only existed for about three years, but it is already the most promising of any round here, and bids fair to be more so every succeeding year.

Affiliated to it is a Cottage Garden Improvement Society, which is doing useful work. Prizes are given to the best cultivated gardens in the parish, and no less than twenty-six entered their names for competition. The Judges were Mr. Carmichael, the late head gardener to the Prince of Wales, and myself, and a most difficult though pleasant task we had to perform.

The prevailing feature of the Show was, of course, the vegetables, and more particularly the Potatoes. I was again Judge, with the help of a local seedsman, and never since I was at school have I had such a hard task allotted me. Fancy me, your "WYLD SAVAGE," your demented rosarian, set down to judge fifteen entries of early round Potatoes, and with aching back and starving inwards to adjudicate on twenty-two entries of Cabbages, three in a lot!—your unfortunate correspondent, accustomed to sniff the nectar of Roses, so coming down as to inhale the perfume of fourteen stands of Onions, three of each tied in a bunch! I think even the "PARSON'S GARDENER" will pity me. I was all right when I got to the flowers, but from 11 to 2 I was kept at the vegetables. There were four kinds of Potatoes, and on an average about ten entries in each, and this occurred in two divisions, for there were both members' and cottagers' exhibits to be judged. I sustained myself in this arduous labour with the thoughts of fruit. "The Judges have the option of tasting all kinds of fruit except Pines," I said to myself over and over again as I went on at Parsnips, and Carrots, and Rhubarb; but when we came to the fruit there was by no means that bewildering quantity that I hoped to see, and what there was, was of a nature more to be appreciated in tarts than for eating uncooked. In fact, they were tart(s) in themselves. Currants of various hues, but of the same unvarying sourness; Gooseberries large but not sweet; and Apples of such a hard unpromising character as to stop all raids. One dish of dessert Apples there was.

"A Golden Pippin!" I shouted out with the same ecstasy as Columbus hailed the sight of America, and in went my teeth, entirely forgetting as I did that this excellent Apple is what is called a late-keeping sort. My fellow Judge watched my face with interest—he knew. "Ah! I thought you were a little rash," he said, as he saw anguish spreading over the face not only of a "WILD SAVAGE," but one who apparently was suffering from excruciating toothache. At last, far away in the cottagers' tent, we espied a dish of splendid Cherries. "Are they Morellos?" I ask with fear and trepidation. "They look like it; fine, dark ruby complexion, splendid Cherries. Shall I try? I will. No, they are May Dukes, splendidly ripe." "Stop," said my fellow Judge; "there is no competition, we cannot taste them."

The flowers were very attractive, and in order to encourage the cultivation of garden flowers and herbaceous plants special prizes were given, and I had the satisfaction of judging about eight exhibits of such flowers as have almost disappeared from the gardens of the wealthy; and the various collections of wild flowers staged by school children were most interesting. We were four hours judging.

After sundry amusements the prizes were paid to the fortunate winners. The Judges were cheered (most wonderful event), and so ended one of the most successful cottage exhibitions that has ever been seen by a—WILD SAVAGE.

CARPET BEDDING AT CLEVELAND HOUSE.

LIKE many others who have read of the beds which have now become famous, I resolved to avail myself of the opportunity kindly afforded by Mr. and Mrs. Ralli and judge for myself how far the reputation of this garden was merited. My visit to them has enabled me to dispel a popular idea respecting these renowned beds which I do not think has been fairly examined. I heard more than once when in London that "the Cleveland House beds ought to be done well, because the place is so small and the beds so few." I have somewhere seen it stated that by constantly repeating an error it becomes accepted as truth, and I cannot help thinking that the carpet beds in question afford a case in point. Not once did I hear the popular notion questioned, and the smallness of the beds appeared to be tacitly admitted; yet I make bold to affirm—not looking at the matter with London eyes, and not being embued with metropolitan notions and perhaps prejudices—I make bold to affirm that there is as much carpet bedding in the little garden at Cleveland House as in either of the great parks of Battersea or Hyde. So much for a popular error—a London notion—and, may I add, a countryman's correction, for there is nothing like starting fair. It is the more agreeable to make this correction, because it does not detract in the slightest degree from the decorations in the parks, which are of such excellence that both the Government which provides them and the public who enjoy them may justly be proud of the results. The remarkable beds, then, which I shall attempt to describe are not the few small patches represented, but are really extensive; they are also distinct from all others, and afford evidence of great taste in design and skill in workmanship that must be admitted by all who see them. The beds are masterpieces of decorative art, and should be seen by all who are interested in this mode of garden embellishment.

The more laboured the attempt to describe them minutely the greater probably would be the failure; a few words, therefore, need only be used, giving an outline of the character of the decorations. Let us take the centre bed in the design. It is 12 feet in diameter—a novelty of the most decided kind. The term "carpet bed" is quite inappropriate as applied to this example of decoration. Fancy a huge hollow and rather deep saucer-like dish 12 feet across with a rim a foot in diameter, and in the centre of this dish a raised mound, formed after the style of an inverted bowl, this mound being about 3 feet across the top and proportionately wider at the base, and about 3 feet high. Such is the ground-plan of the bed, and now for the mode of decoration. In the centre of the mound is an elegant specimen of *Dracæna indivisa*, rising from a circular base about 2½ feet in diameter of *Mesembryanthemum cordifolium variegatum*; this is surrounded with a ring 2 inches in diameter of *Sedum Lydium*, followed by a circle of *Echeveria secunda glauca*. Next comes a broad band about 8 inches wide of *Sedum glaucum*, in which at regular distances are richly berried clusters 6 inches across of *Nertera depressa*, each plant of *Nertera* being encircled with very small plants

of *Echeveria secunda glauca*. Next comes a narrow belt round the mound of *Alternanthera amœna*, margined with *Echeveria*. At intervals in this outer circle eight chains of the same plant descend down the sides of the mound, terminating in the lowest part of the bed—the "dish" of the saucer, each chain encircling a miniature mound of succulents, out of which springs a small plant of the silvery *Chamapucea Diacantha*. There remains now the groundwork decoration of this design—the whole interior of the saucer and sides of the central mound. It is simply planted and densely covered with the dwarf emerald green *Sedum Lydium*. There is yet the rim of the saucer to be noticed. It is a foot or more in width and rather rounded. The inner and outer circles are *Echeveria secunda glauca*, next two narrow circles of *Alternanthera amœna*, the centre of the rim being a band 6 inches wide of *Sedum glaucum*, dotted every 3 inches with small round plants of *Nertera depressa*. Such is the outline of this bed—a bed as striking in appearance as it is original in conception and artistic in execution. Every part is excellent, and, being chiefly of neutral colours enlivened with the brilliant bead-like clusters of *Nertera*, the more and the longer it is looked at the better it pleases.

Surrounding this central bed six other beds are formed. These beds are each 21 feet in length and 8 feet across at the widest end, tapering to 4 feet at the ends next the central bed. These are planted in duplicate. It is no easy task to describe them, as all will allow who have inspected them. It is popularly supposed that carpet bedding cannot be successfully carried out without dwarf blue *Lobelias*, *Alternantheras*, and *Golden Feather*; but the most striking pair of beds in this design contain no *Lobelia*, no *Golden Feather*, and only a faint streak of *Alternanthera*. The planting is somewhat as follows:—A row of raised diamond-shaped cushions is arranged down the centre. The groundwork of the bed, which is hollowed after the manner of a shallow boat, is carpeted with the green *Mentha*; above this the diamonds are raised, the largest at the wide end of the bed, the others diminishing in size to the smaller, the whole of them being banded and chained together with *Echeverias*. These diamond-shaped cushions are formed with *Sedum acre elegans*, each having a central plant of *Pachyphyton bracteosum* except the two end diamonds, the largest of which contains a small plant of *Dracæna australis*, and the smallest, a still smaller one, of *Yucca filifera*. And now to the edge of the bed. The outer margin next the grass is of *Echeverias*—a straight row; then *Sedum glaucum* dotted with *Nertera*, and an inner margin of *Echeverias*, but this inner margin is scalloped, the points terminating exactly between the points of the central row of diamonds in the body of the bed. These points end in raised mounds of succulents, each being surmounted, and this constitutes the great beauty and novelty of the bed, with a fine plant of *Nertera* quite 6 inches in diameter. This row of brilliant summits—there are fifteen of them—elevated above the green ground of the *Mentha* produce a remarkable effect—soft yet sparkling, brilliant yet chaste, the full beauty of which cannot be appreciated without being seen. The other beds are totally different in character and are extremely effective. It is not necessary to describe them, but the "square bed," which is 21 feet long by 9 feet wide, should not be passed in silence.

This is by many considered to be the most highly finished bed of all. Near each end of the bed are two pincushion-like mounds, 2 feet in height, surmounted with *Dracæna indivisa*, the four corner edges, the seams of the pincushion, being formed with a double row of *Echeverias*, *Sedum glaucum*, and *Nerteras*. The tops of the mounds are also covered with *Sedum glaucum* dotted with *Nertera*. In the centre of the bed is a raised circle nearly 3 feet in diameter containing a plant of *Agave filifera* in a carpet of *Sedum acre elegans*, and edged with *Echeverias* and *Alternantheras*. Surrounding this raised circle, and connected with it and also raised, are eight small circles of the silver *Sedum* and *Echeverias*. The edge of the bed, which is very chaste, is formed with a band about 4 inches wide of *Sedum acre elegans*, two narrow lines of *Alternantheras*, and an inner and outer margin of *Echeverias*. The groundwork of this fine bed and the sides of the mounds are planted with *Sedum Lydium*.

There is also a raised bank on one side of the lawn about 70 yards long by 4 wide; this is carpeted in the "highest style of art" with *Golden Feather*, raised chains of *Mentha*, panels of *Alternanthera*, and triangles of *Sedum glaucum*. It is a splendid bank which cannot be described without a diagram, which I had not time to trace. The Vine border is also

elaborately planted. The high character of the building is not the only charm of this garden. The plants are splendid—the chief prize-winners of the year—Heaths, Crotons, Nepenthes, Palms, Alocasias, &c. *N. Rafflesiana* has more than fifty fine pitchers; the Vines are carrying an excellent crop, and have made capital growth for future crops. The kitchen garden is well worked and cropped—in fact the condition of the garden in every department testifies to the industry and skill of its successful manager. The owners of the garden, Mr. and Mrs. Ralli, deserve a hearty vote of thanks for generously permitting all comers to inspect the flower beds, &c., on one day in each week—Friday. The beds will continue attractive for a few weeks to come, but the sooner they are seen now the better.

I have now to state a "surprise." A letter informs me that this is the fifth and last season of Mr. Legg's services at Cleveland House, but a gardener who has given such good proof of his competency and has been so signally successful cannot be long out of harness.—A NORTHERN GARDENER.

THE POTATO DISEASE.

THIS much-dreaded visitor made its appearance here about three weeks ago. It appeared first in the early sorts of the Potato. Up to that time the tops of all sorts of Potatoes looked remarkably well, and as the damp cloudy weather continued, with seldom more than one dry day or two in the course of a week, great fears were had respecting the crop. When the Potatoes were attacked the tops of some were pulled off. But pulled off or not, all very quickly rotted and had a very disagreeable smell. The later sorts are now nearly all going bad, and soon there will not be a green top of Potatoes to be seen anywhere in the neighbourhood. Some are lifting their crops and spreading their tubers out in sheds, &c., and places under cover, so they can be seen and easy to get at, in order to pick out the decaying tubers. How would it do to cover them over for a few hours with fresh-slaked lime? Could it be any means to arrest the disease or keep the air from operating upon them? From present appearances it is feared that one-quarter if not one-third of a good crop is already affected.—G. DAWSON, *St. John's Nursery, Worcester.*

FRENCH ROSE GARDENS.—No. 1.

IVRY-SUR-SEINE.

A ROSARIAN in Paris naturally bethinks himself, amongst other things, of French Rose-growers. Accordingly I attempted a visit to Monsieur Levêque, "Grand Fleuriste" at Ivry. Starting from the Pont du Roi as it calls itself, or Pont National as the tickets call it, or Pont Napoleon as it going to be? I journeyed down the Seine on one of the river boats. Very charming those happily-called "hirondelles" certainly are, as like our Thames boats as an Arab is to a cart horse. It is a short one hour's sail. First past the still ghastly skeleton of the Tuileries wing; but it will not be a wreck long. Paris is busy building; so busy, they seem almost glad of an opportunity of making their splendid city even yet more magnificent. Then past fine old *Nôtre Dame*, and where the Hotel de Ville was, now it is a wilderness of scaffolding sky high; then on the right the Halles, those huge wine stores of Paris; then the pleasant groves of the Jardin des Plantes; its animals, a travelling companion assures me, were not eaten during the siege; under some pretty bridges, one embossed with a big N, and I am at the landing-place for Ivry-sur-Seine. A hot half-mile takes me up into Ivry proper. Its inhabitants appear either asleep or in slippers, always excepting certain sturdy blouses at work in the nursery gardens. I pass one small Rose garden, where rows of Potatoes alternate with Rose plants, and every Rose that has failed is replaced with a vegetable. Certainly every inch of ground so near Paris is made use of.

With some difficulty I make out in the main street M. Levêque's establishment. Unhappily he is not at home. Under the obliging guidance of Mdlle. and M. Gaston Levêque, of the mature ages of twelve and eight, we traverse his various terraces, but he is not to be found. There is much besides Roses under cultivation. The land appears light, but well supplied with *articles de Paris* in the shape of heaps of rich refuse from the great neighbouring city. An admirable arrangement supplies water in abundance; huge wine vats being sunk at intervals are connected by leaden pipes, into which a deep horse-worked well is constantly emptying. Rows of splendid Tomatoes showed from whence mine host of the Valois in the Palais

Royal might have obtained those irresistible Tomatoes *au gratin*. There are also large beds of Melons and Vegetable Marrows. The way these latter were being grown is a perfect specimen of French ingenuity. Vast quantities of cloches (bell-glasses) out of use have been packed together and thatched over with straw, and now the huge plants are trailing at will over them, having, as it were, a hothouse below instead of above. The light wood and wire fence, so often seen by the side of the pathway, is here constructed chiefly of Briar stocks that have failed and died. They certainly would have been burned in England, but France is the home of economic ingenuity. They were busy budding Roses on low Briars and Manettis, and such Roses as were in bloom seemed equally busy setting Rose haps.

But the new Roses that I went to see. My companion kept assuring me (for a workman had succeeded to my little companions, Garston had quite enough of walking over rough ground in slippers), that when M. Levêque was found I should see all the *nouveautés*. But, alas! he never was found; consequently, Messrs. Editors, "Story indeed, sirs, I have none to tell you," except that the, I hope, more fortunate traveller than myself may vary the return to Paris if he chooses, as I did, by taking the chemin de Fer d'Orleans, which will deposit him close to the Jardin des Plantes.—A. C., *Hotel de Louvre.*

CAMPANULA MEDIUM CALYCANTHEMA.

In the *Journal of Horticulture* for 16th of August is a letter from Mr. J. Pithers respecting the *Campanula Medium calycanthea*. I have tried it for two years both in pots and in the open ground. I flowered this year some plants in my borders, which attained a circumference of a yard full of large white flowers; I have also had some purple, but not so large. Some have flowers consisting of a perfect bell within a bell, while others have the bell corolla issuing out of the calyx, with broad segments of the same colour as the corolla.

I sent some flowers to the Norwich Rose Show, which attracted much attention and were favourably noticed in two local papers.—JAS. C. BARNHAM.

FLORAL DECORATIONS AT THE AGRICULTURAL HALL.

THESE are worthy of notice from their great extent and high character. The prizes of £50, £30, £20, £15, and £10 in one class are somewhat of a sensational nature, but considering the great extent of the groups—70 feet by 5 feet and 11 feet high, also that the plants must remain for a week to be injured, and further that the competitors are not likely to receive a single "order" from the spectators, the prizes are not of such great value as at the first sight they appear to be.

The prizes named were awarded as follows:—First to Mr. Wills, second and third to Mr. B. S. Williams, fourth to Mr. Turner, Slough; and fifth to Mr. Ley. Mr. Wills's collection consists of tall Palms and other ornamental-foliaged plants rather thinly disposed, with groups at their base of Gladioluses, Lilliums, &c., and an irregular fringe of cut flowers of Orchids and other stove plants arranged in a carpet of Lycopods, with Pitcher-plants elevated on stands; ripe Pine Apples in pots and Tomatoes; also an arch of Vines bearing fruit, are employed in this highly artistic group. Mr. Williams's contribution is a valuable one—too valuable considering the risk of injury by gas and the dry atmosphere to which they are subjected, for the Palms, Tree Ferns, and specimen flowering plants are splendid. Mr. Turner's group is composed chiefly of Palms and very fine examples of *Lilium auratum*, and Mr. Ley's of general decorative plants. These groups are arranged in the promenade surrounding the inner circle of the immense hall. In the circle—the auditorium—are semicircular groups about 20 feet in diameter. These are on grass banks. Mr. Wills secured the first and second prizes in this section with beautiful collections of plants and several excellent dishes of fruit, Mr. Turner being placed third and Mr. Williams fourth. Mr. Turner's Dahlias had a fine effect by gas light, and had they been arranged in a wide bank of moss instead of in exhibition boxes the groups containing them would have won a higher position. Mr. Williams's group is very artistic. It represents a lawn and carpet bedding, the trees on the lawn being specimens of *Cocos Weddelliana*. In the next class, the spaces being 12 feet by 2½ feet, Mr. Williams secures the first three prizes, and Mr. Wills the fourth. Messrs. Dick Radclyffe

and Co. secure the chief prizes for fountains, garden seats, tools, and appliances; but these "general" classes are comparative failures—a farce, perhaps, is the proper word. The plant decorations are excellent, and, notwithstanding the seemingly high prizes, this system of embellishing a large hall is probably less costly than by employing floral decorations in the orthodox manner.

The association of music and flowers is appropriate; both are attractive, and both are provided liberally at the Agricultural Hall, continuing throughout the week. Mr. F. W. Wilson, late of the Crystal Palace, proves as efficient as ever as floral manager.

BOOKS.

The Colorado Potato Beetle. Illustrated and Described by Dr. ANDREW WILSON, &c. W. & A. K. Johnston, Edinburgh and London.

We recommend this work to our readers. It will enable them to identify the marauder should it attack their Potato plants, and it notes the remedies that have been suggested. The coloured portraits of the insect and its larva are very good. We can afford space for only one extract. "The chemical remedy most in vogue is Paris green, a powder consisting of Scheele's or Paris green (the arsenite of copper) added to plaster of Paris, to ashes, or to flour; one part of the former being added to twelve or fifteen parts of the latter substances. With this powder the infested Potatoes are dusted, this treatment appearing to have no injurious effect on the plants, although it has been remarked that the subsequent year's crop is usually of inferior quality and exists in diminished quantity. It is hardly necessary to remark that Paris green is a highly poisonous substance, and that great care must be taken in its application. A convenient method of application of this substance is that by means of an extemporised duster or dredge, such as may be made by punching a number of small holes in the bottom of any old tin vessel. This apparatus may be tied to a stick, and can be employed with great facility in the distribution of the powder."

Various Experiments for the Production of New and Desirable Grapes, and a Description of Forty Varieties obtained by Hybridisation. By G. HASKELL, Ipswich, Mass.

Two years since we noticed some of the seedling Grapes sent to us by Mr. Haskell, and commended especially two which had the Black Hamburg and White Chasselas for their male parents. Mr. Haskell has continued his experiments, and the pamphlet, of which we have stated the title, records the results. We will copy one paragraph because it relates to a subject now especially demanding attention.

Recent experiments in France have shown that the most effectual eradication of the Phylloxera was by flooding the ground and thus drowning the insects. As the Riparia of this country flourishes, and really does best in wet bogs and meadows, even when the roots are immersed in water all winter and the soil is saturated all summer, may we not expect that this trait will prevail in some of these hybrids and make them almost proof against the Phylloxera, especially if planted in such wet soils? I shall place them in such soils and localities, and hope others will do so too, that the experiment may be fairly tried.

NOTES ON VILLA AND SUBURBAN GARDENING.

COLEUS VERSCHAFFELTI and V. splendens are among the very best of foliage plants for richness of colour and effectiveness in the flower garden. They are extensively used in working out the various designs for scrolls, panels, or other pattern bedding, in which cases they are generally planted closely so as to shelter each other, and the tops are kept pinched to the uniform height and shape of the pattern. When massed in larger beds and edged with Centaurea ragusina few beds are more beautiful. Cuttings of Coleuses strike very freely, and no plants are more easy to grow; they require a position near the glass, a tolerably rich soil, plenty of water when growing, and a temperature during the winter of not less than 45°. Let no one try to grow these plants who cannot maintain this temperature. If only just a few plants can be thus wintered the quantity required can be raised with the greatest rapidity in the spring with the help of a dung frame, for every little side shoot or top will soon make a bushy plant.

The very pretty and dwarf-growing Alternantheras are also extensively used in modern bedding, and require much the same treatment as Coleuses. Cuttings inserted thickly, or old plants taken from the ground and potted, if kept in the same temperature as recommended for the Coleus, will furnish abundance

of cuttings for increase in the spring. A. amœna, amabilis, magnifica, and paronychioides are the best. Iresine Lindenii as a dark bedding plant is also very useful, and will flourish under the same treatment as the Coleus; it is a decided improvement on I. Herbstii, being brighter in colour and of much better habit.

The several varieties of bedding Lobelias are exquisitely beautiful, and are well adapted for small beds or for edgings around larger beds. Their dwarf growth and continuous-blooming properties are not to be equalled by any other bedding plants we possess. Lobelias are easily raised from seed sown thinly at the present time, the seedlings being wintered in a greenhouse; or seed may be sown in heat early in the spring. But though the majority of the seedlings come true they are not entirely to be depended on, and therefore a stock of any particular variety, to keep it select and true, must be perpetuated by cuttings. If stock plants are kept on a shelf in a greenhouse throughout the winter many of them will become dense masses, and young rootlets will start from the base of each shoot: these shoots will strike very freely. The varieties of the L. pumila section are now mostly used, and a double variety exists which in some places and seasons answers well, but in others we have seen it a complete failure.

Ageratum Imperial Dwarf and one or two other varieties are very useful. Their immense bunches of lively lavender flowers together with their dwarf habit render them valuable as bedding plants. They can be either increased by seed or cuttings. A few old plants cut down and potted in the autumn and wintered in a greenhouse afford an excellent supply of cuttings in the spring. Heliotropes are not now as much used for bedding purposes as formerly, but we recently saw two beds of Miss Nightingale at Kew very even and beautiful, and the perfume from them was delightful. Heliotropes are easily propagated by cuttings and can be wintered in a warm greenhouse.

Of all plants used for their golden foliage the Golden Feather (Pyrethrum) is perhaps the most popular. It is readily raised from seed. Seedlings raised annually have not that tendency to bloom as have cuttings or older plants. Sow in March, and prick out the seedlings when large enough to handle; or a little seed may be sown now in the open ground. As a companion plant to the Golden Feather is the Golden Chickweed (Stellaria graminea aurea); it is very neat and effective and is quite hardy. For covering the ground closely and for producing a creamy yellowish mass Mesembryanthemum cordifolium variegatum is very well adapted. A few pots of cuttings inserted at once will furnish a sufficient supply in the spring.

The Centaurea makes a noble edging plant, but is not so easy to strike as some of the plants above named; but cuttings taken off now will strike freely enough if ordinary care be taken to prevent damping. Keeping them in small pots and somewhat dry during the winter, with plenty of air, is the best means of preserving a stock of this pleasing white-foliage plant.

Succulents are now extensively used for bedding purposes, especially Echeverias, Sempervivums, and Sedums. They are increased by offsets. Frost does not injure these so much as damp around the collar. If placed in a dry shed, or along the side of a wall where wet is kept away by coverings, plants may be preserved through the winter.

Leucophyton Brownii is a very neat and one of the most beautiful of dwarf foliage plants ever introduced. Cuttings of it strike best in a cold frame, where also the plants may be wintered. Its bright silvery appearance is most peculiar but attractive. Gazania splendens is not now often seen, but a good bed on a bright day has a very pleasing effect when the sun shines. Cuttings strike freely, and may be wintered in covered frames.

The dying-off of Calceolarias soon after being planted out has caused them to be less popular than formerly, but we possess nothing so gay when the plants are well grown. To increase a stock of these valuable bedding plants cuttings should be inserted in tolerably sandy soil in a cold frame early in October, allowing them to remain there throughout the winter, keeping out frost by covering the glass with mats, straw, or any other material, giving air on favourable occasions to prevent damp. Though the bedding Calceolaria is not aquatic it is very impatient of drought, and therefore requires deeply trenched and well-manured beds to grow it well.—J. W. MOORMAN.

DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

KITCHEN GARDEN.

We have not done much in this department except to clear-off any crops that had ceased to be useful, making the ground tidy by clearing away the weeds. Sometimes it is convenient to dig in the vegetable refuse, and that is often as good as a dressing of manure. We had a good illustration of this in the spring of the present year. About four acres of ground had to be planted with Potatoes, and two acres of that were sown with Rye in the autumn, and about planting-time the Rye which

was about 9 inches high was ploughed-in, the Potatoes being planted at the same time without any other preparation or any further manuring. The other two acres had a good dressing of farmyard manure and guano, but the part on which the Rye was ploughed-in had the best plants and the greatest crop. We have taken up all the Potatoes, but be it understood none of them are late sorts. Early Ashleaf, Veitch's Prolific, Improved Ashleaf, Schoolmaster, Blanchard, and a local sort named Early Shaw. Disease had attacked most of them, Blanchard most severely. It would certainly have been better if we had dug the crop before the disease had attacked the haulm. When this is done it is necessary to handle the tubers very carefully. We have found that, although the skins are easily injured at the time of taking-up, in less than a week after they set firm and do not suffer from being moved. All the Potatoes which are required for sets next year have been stored in a dark loft. They are spread-out thinly.

After a spell of hot dry weather the ground was dusty dry and hot to the feet. On Wednesday morning for two hours the rain fell steadily and heavily; rather over an inch was taken from the rain-receiver afterwards. The ground was in good order for planting, and Sprouting Broccoli, also Coleworts, were put out in quantities.

VINERIES.

We have pruned the Vines in the earliest house, and will as soon as an opportunity offers make preparations for starting them. One of the houses shows signs of the Vines being exhausted, and we are not surprised at this, as our light gravelly soil is not naturally adapted for Vine culture. We would like to clear all the soil away from the roots of the Vines to within a few feet of the stem, and renew the border in the same way that it was made at the beginning. Our plan would be this: We would begin at that part of the border furthest from the stem of the Vines, and would cut a trench as deep as the drainage; from this trench we would work up to the Vines, removing all the soil but saving the roots. After clearing out the soil to within 3 or 4 feet of the Vines we would see that the drainage was perfect, and would then fill-up the border with fresh compost, raising the roots much nearer to the surface than they were before. The time for doing this is a matter of considerable importance. It would be best to do it immediately the fruit was gathered—that is, if the Vines were in good condition; but if most of the leaves had perished from the attacks of red spider or any other cause, it would not be safe to do it, especially if the compost was formed of turf not quite decayed: the organic matter would heat and start the Vines into growth. Ours will probably be done at the time of starting the Vines, when the gentle heat generated by the decaying turf will probably cause the Vines to start strongly.

Late houses require a little attention in order to perfect the ripening of the Grapes. Should the temperature fall below 65° in the Hamburgh house, or 70° in the Muscat house, it must be kept up to those figures by the heating apparatus—that is, if the Grapes are not ripe; if they are ripe all the attention that will be required is to keep the temperature and state of the atmosphere so that no decay attacks the berries. A high artificial temperature would cause the berries to shrivel, and a low night temperature has a tendency to induce decay. Moisture will not need to be applied artificially. Care must also be taken in sweeping the paths not to raise dust in the atmosphere, which settles on the berries.

Vines in pots intended to be forced to produce early crops of Grapes should now be enjoying a period of rest, either against a wall or in a house with a dry atmosphere and where plenty of air is admitted. It is not desirable to give much water at the roots, but the Vines suffer more from too little than they do from an occasional overdose. It is well to cut the canes back to the length they are intended to be for forcing, as the eyes that remain on the cane will continue swelling while the leaves are in a healthy condition. All the pruning that is required should be done as early as possible, as bleeding generally results from late pruning. If it is intended to start the Vines in October all growth ought to be completed now.

Strawberries in Pots.—We have now completed the potting of these. All intended to fruit late have been potted in 6-inch pots; early sorts, like Black Prince and Keens' Seedling, in pots a size smaller. They are just under 5 inches in diameter inside measure. The plants root freely and make rapid growth after potting, and the object of the cultivator is to take advantage of this in order to have the crowns large and well developed before the dull days of autumn. The plants are placed in a favourable position where they receive most of the sun's rays, and the pots must on no account lack an abundant supply of water. An attack of red spider will utterly ruin the prospects of a good crop. On the first appearance of this pest lay the plants on their sides, and thoroughly syringe the under sides of the leaves with soapy water to which a little tobacco liquor has been added. Runners are also produced very freely on the plants, but these must be removed as fast as they are formed, as they must to a certain extent weaken the crowns.

PLANT STOVE AND ORCHID HOUSES.

We have had a season of respite from potting or other important operations in this department, and have taken the opportunity to look over all plants that are likely to have any of that terrible pest the mealy bug. We have again and again had it down so that it has been almost annihilated, but we have not yet destroyed the scourge entirely. It is now a good time to thoroughly re-arrange the plants, and any unwieldy specimens which are not required for decorative purposes next year should be destroyed, and only the best specimens be allowed to remain. What can be more unsightly than to see plants of a scandent character growing into one another and forming a tangled mass, which becomes a breeding ground for insect pests? See that all plants are neatly but not formally trained, and if possible they ought not to touch each other. Large specimens must stand back from the front of the stage or bark bed, and some neat, healthy, small plants ought to be placed on the outer edge sufficiently large to hide the pots. They ought not to be plants that are intended to make good specimens, as growing them under those of a large size will probably injure them. It depends very much upon the manner in which plants are arranged as to whether they will make handsome specimens or the reverse. Very careful attention is requisite in order to ascertain the requirements of the various subjects in each house. We have found a specimen would do well in one position, which on being moved to another part of the house did not succeed. The reason of this is not far to seek: some plants require to be near the glass and fully exposed to the sun and with free air around them, others require to be grown and flowered in the shade.

Orchids do not require a large amount of attention at this season, but all that they do require must be freely rendered at the right time. Dendrobiums which have been well supplied with water at the roots and often overhead must, now that their growth is completed, be treated to a drier atmosphere, and water must only be applied when the plants really require it—that is, when the compost is rather dry. As the season advances water must be almost entirely withheld in the case of most of the deciduous species. Cattleyas must not have much water at the roots after this. Allow the compost to be dry before applying any. *Lælia purpurata* is now starting into growth, but the plants do not seem to make much root at the same time; and water, even when the growths are in the course of formation, must be applied with caution. *Calanthes* have also completed their growth, and the spikes in some instances are coming up. We grow our plants in small pots for the size of the bulbs. Three large bulbs in a 5 or 6-inch pot will give us from four to six spikes 2 and 3 feet in length. We have not yet reduced the atmospheric moisture, but now that there are heavy dews at night, and the rains have at last touched our district, we must act with caution in this respect.—J. DOUGLAS.

TRADE CATALOGUES RECEIVED.

TO CORRESPONDENTS.

* * All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

VEGETABLE MARROWS (*Major M.*)—They appear to have been quite overlooked. If you can send other examples they shall have our attention.

RAISING *KALOSANTHES* FROM SEED (*T. J. H.*)—The seed pods should be cut when ripe, and may be kept after they are dried in a cool dry place until spring, the seed remaining in the pod until that time. Drain a pot or pan half its depth, placing over the drainage some of the rough of the compost, which should consist of equal parts of sandy fibrous loam and sandy peat with about a fourth of silver sand, well incorporated and passed through a quarter-inch sieve. Let the soil in the pots be rather firm, and the surface quite smooth. Water gently and scatter the seeds evenly over the surface, the pods being broken over the pot. Scatter a little fine soil over the seed and place in a hotbed, keeping the surface regularly moist, but avoid making the soil sodden. In the young state the seedlings require to be very carefully watered,

for an excess will cause them to damp. The seedlings should be kept near the glass and have air moderately. When large enough to handle they should be gently lifted with a knife or pointed piece of wood, and potted-off singly in small pots, returning them to the frame, shading for a few days until established, after which they may be hardened-off and placed in a cold frame, placing the pot on ashes. In August they may have 4½-inch pots, and in September be removed to a light airy position in a greenhouse, keeping rather dry over the winter. The strongest plants will flower the following year. There is no advantage in raising the plants from seed, and superior varieties can only be obtained when the best of the present varieties have been crossed—artificially fertilised.

EXHIBITING (T. Richardson).—Exhibit any eight that are best of their kind.

CALCEOLARIAS AND PRIMULAS (W. B.).—Calceolaria seed may be sown now in light sandy soil pressed rather firmly in pots or pans. The soil should be watered an hour previously to sowing the seed, which should be scattered thinly on the surface and be slightly pressed. Cover each pot with a square of glass, and place in a cool, moist, dark frame. The moment the seed germinates light must be gradually admitted. The seed pans and frame should be so managed that no water will be needed until the seedlings appear, the soil being kept moist by placing the pots in saucers of water. It is fully late to sow Primulas now, and you will do more wisely by purchasing a dozen or two of small plants ready for being potted.

INSECT ON GLADIOLI (S. E. W.).—It is the *Julus terrestris*, one of the snake millipedes. We do not think they cause the decay, but subsist on the decayed parts.

TAKING UP POTATOES (Idem).—The tubers have done increasing in size when the stems begin to be yellow.

VINE BORDER (A. Young Gardner).—Full directions are in our "Vine Manual," price 2s. 8d., free by post.

PEA.—We have mislaid the inquirer's name. The Pea is the Mummy Pea, and known also as the Crown, Bunch, and Cluster Pea.

TRAINING PEACHES IN WALL CASE (R. H. A.).—It will be much better to train the trees to a trellis fixed about 10 inches from the glass. We would, of course, allow the trees to remain against the wall, but would plant others about a foot from the front wall, or rather where you have placed the line of oak posts.

SOWING POLYANTHUS AND PHLOX DRUMMONDII SEEDS (J. C.).—If you have Polyanthus seeds sow at once, but it is almost too late to expect flowers next season. They flower abundantly and strongly from seeds sown in May. Sow the Phlox in March and place the pots in a hotbed, the plants will flower during summer. We once had some fine plants of this Phlox which flowered in the greenhouse during May and June, and were much admired. The seeds were sown at the end of August, and the plants were wintered on a shelf in a light and cool house.

WEEDS ON GRAVEL (T. P. L.).—No available application will prevent the weeds growing. Asphalting the surface would prevent their appearing.

SLUGS IN HEAVY SOIL (E. R.).—Your most effective remedy will be to pare and burn the top spit of your soil. It will annihilate the slugs and improve the staple.

BOILER (E. M.).—We presume the apparent neglect arises from the great demand. Write again to the makers.

NAMES OF FRUITS (W., Luton).—Please to send them later, it is too early in the season to name late Apples.

NAMES OF PLANTS.—Specimens are sent that cannot be recognised, they are so dried-up. They ought to be sent in a box with a little damp moss about them. (*Arthenice*).—1, *Spiraea Umaria*; 2, *Lythrum Salicaria*; 3, *Epilobium hirsutum*. (*Young Gardner*).—1, *Centranthus ruber*; 2, *Chrysanthemum segetum*; 3, *Pyrethrum frutescens* (?); 4, *Alyssum maritimum* variegatum. (*Winchester*).—*Abutilon Thompsoni* variegatum. (*C. Friaby*).—Winter Cress (*Barbarea vulgaris* or *B. praecox*). (*W. L.*).—1, *Pulicaria dysenterica*; 2, *Senecio cruciifolius*; 3, *Centaurea nigra*; 4, *Agrimonia eupatoria*. (*G. Wall*).—1, *Spergula nodosa*; 2, *Heclosciadium nodiflorum* var. *repens*; 3, *Sceleranthus annuus*. (*W. M. E.*)—*Papyrus antiquorum*. See also reply to "W., Luton."

POULTRY, BEE, AND PIGEON CHRONICLE.

LOCAL REPORTS ON POULTRY.

We are afraid these are more amusing than edifying. All are aware of the utter helplessness generally of a reporter for a local newspaper when he is turned into a poultry show and told to make a report. He knows a fowl and a Duck by sight, and is probably acquainted with a Christmas Turkey or a Pigeon pie, and this is often the consummation of his poultry knowledge. What does he do? One of two things: he either scrapes into conversation with some gossiping poultryman and writes down in shorthand from his lips, or else he gleans a few stray names and ideas here and there, and concocts a hash for the country residents. In the former case the tips he is given generally are in favour of some particular person's exhibits, or the worthlessness of some opponent's. In the latter case the result may be something of the nature which we will proceed to describe.

"What are Mangle-crested Piles? I should be so much obliged if you will let me hear where I can see some." This we had from an exhibitor on a postcard. We had no idea what "Mangle-crested Piles" were, and wrote for further particulars. On the arrival of a second note we were told that a pair of this breed won the cup and first prize in Class 21 at Hereford, and a local newspaper was then quoted as the authority. We afterwards saw a copy of this interesting organ, and really the report was so delicious in the positive hopelessness of its poultry knowledge that we must quote from it to exemplify our case.

We are told in the first place that the first-prize Dorking hen was most beautifully marked, and that "the pluff was exceedingly fine." Even supposing that "pluff" was a misprint for "fluff," we do not often hear of a Dorking's fluff! In mentioning Lady Dartmouth's first and second-prize Light Brahma cocks they are termed "elevated companions." The first-prize Golden-pencilled Hamburgs had legs which "appeared as if cut out of a piece of stone," they were so magnificent. We cannot possibly remember a worse simile, for Hamburgs are hardly ever still, and their legs are very slender at all times. In Class 19 the first prize went "to a pair of Black Piles." This is charming, but our readers must not imagine that "Piles" is a misprint for "Poles," as Class 19 was the French class. In Class 21 "the cup and first-prize were awarded to a pair of Mangle-crested Piles," "and the second to a pair of White-crested Piles." The third prize in the sale class we also read went to "White-crested Piles." In Class 23 all the winners were Dark, or else the reporter's brain must have been dark, for "Dark Brahmas, Dark Cochins, and Dark Brahmas" were the three victorious pens. Lady Dartmouth's celebrated Sebrights, which won second and third prizes in the Variety Bantam class, are termed "Silver-spangles." And so we could go on; but we have given enough to show the perfect rubbish of the notes in question, though we are told in a private sort of way that they were "written by an old fancier," at least we have those words written in pencil at the top of the report in question.

There are many fanciers in a quiet way. A tradesman who keeps his Brahmas or Cochins, a farmer who keeps his Hamburgs or Dorkings, the squire of the parish or chief landowner who keeps at his home farm some particular breed or other, such as these do not call themselves "fanciers," merely lovers of poultry. They enjoy their birds as a recreation, and take in no weekly poultry periodical, or try to keep themselves *au fait* in the onward progress of poultry matters. They look forward to their county or city show, and perhaps then exhibit a pen or two, when they will read afterwards with relish the half column which the local daily or weekly paper gives concerning the exhibition. They must be edified; still to them a report such as the one from which we have taken extracts reads no doubt perfectly right, and perhaps the one envies a neighbour's "Mangle-crested Piles," while the other would like to see his own Dorkings more heavily "pluffed." These little things, however, are thorns in poultry cultivation, for after having composed such a report as we speak of the writer will perhaps imagine he is "gifted," and the result will be an article on "egg-selling" or "egg-buying," or "preparing for a show" or "fattening fowls," in which he is able to work a real evil; and we have before now seen such articles in leading county newspapers which we know positively have not only done much harm, but have actually led to the discontinuance of poultry-keeping from the imaginary roguery which an ignorant writer would attempt to disclose.

If a local newspaper requires notes on any particular section of a show he should surely go to the proper source to obtain them, and we hope those proprietors or editors who may see these lines will take the subject to heart, and either content themselves with a few words on general points, or omit the subject altogether rather than allow themselves to be laughed at, and pure nonsense written about a most healthy and profitable pastime.—W.

ROCHDALE POULTRY SHOW.

This grand Exhibition of stock, poultry, &c., was held in the grounds of Clement Royds, Esq., on the 22nd inst., when the day proved the most disastrous of any in our experience of twenty-five years, the rain falling in torrents from noon until night, making the turf one perfect bog and drenching all the exhibits to such an extent that we consider correct judgment or criticism was utterly impossible. The Show was one of the best the Society has ever held, if not the very best, which speaks volumes for the management.

Poultry were for young birds with the exception of some classes of Ducks, Geese, and Turkeys, and the selling classes; and some excellent chickens were shown, although with all the talk of large numbers reared this season there seems to be a dearth of really good specimens in some classes. Game were of fairly good quality, although we have seen them better here; the *Cochins* and *Spanish* being about the best of the large section. *Polish* proved very good in entries and the quality very fine, the winners being most compact in crest and straight in back, a point sadly overlooked in this variety. *Hamburgs*, as may be expected, were a capital lot, this Show more than any other proving a kind of feeler as to the position of young stock, and among them were some of the best birds we have ever seen. *Ducks* and *Geese* were very good and well shown.

The show of *Pigeons* was very large and good, but on account of the weather we prefer not to criticise the awards.

POULTRY.—SPANISH.—*Cockerel*.—1, J. T. Parker. 2, J. Walker. *vhc*, J. Aldridge, J. Roberts. *Pullet*.—1 and 2, J. Powell. **COCHINS.**—*Ginamon* and *Buff*.—*Cockerel*.—1, H. Tomlinson. 2, G. Sidgwick. *vhc*, T. Lees, C. Sidgwick.

and S. W. Marshall, *chc*, S. Lyson, E. Gould, C. Thompson, 2 J. S. Robinson, 2 D. Oldfield, *extra*, 3. Howarth & Whittingham, *whc*, T. & E. J. Fell, *Broken-coloured*, J. T. Moss, 2 D. F. E. J. Fell, SILVER-GRAY.—1 and 2 T. & E. J. Fell, 3 J. S. Swinbenham, *whc*, T. & E. J. Fell; D. Oldfield, F. Foster, D. Oldfield, J. Robertshaw, *whc*, 2 D. Oldfield, 3 J. Foster, 2 J. S. Robinson, 2 D. Oldfield, J. Robertshaw, ANGOA.—1, D. Oldfield, 2 J. S. Robinson, 3 E. Robinson, *whc*, J. W. Baron, T. & E. J. Fell; D. Oldfield, 2 J. S. Robinson, 2 T. & E. J. Fell, 3 A. Atkinson, *whc*, T. & E. J. Fell, T. Moss.

IN consequence of the various little notes from Stoke Park we knew fairly well before the list came to hand what to expect. We imagined Mr. Wragg would be on the spot and send forth a schedule which would be worthy of his fame. The list of prizes and the array of cups are most tempting. We only regret that Weymouth and Aylesbury should clash with this Show. It will be the first grand chicken Show of the season, and to that all must look forward for a comparison of their particular birds. It would take too much space to particularise the classes, and we can only recommend exhibitors who have not already been supplied immediately to apply for a copy of the schedule, as nearly every existing fancier, whatever his breed may be, can here find scope to exhibit with a moderate entrance fee; but as the entries close on the 5th of September there cannot be much time to lose. The list of patrons is large, and we find among them fanciers in all grades of society, thus testifying to their confidence in Lady Gwydyr's manager as the Secretary. Of the rules, which are carefully drawn up, we would draw all fanciers' particular attention to Nos. 4, 8, and 10. Of the plate

The doe make rather awkward mothers sometimes, and do not always bestow quite so much attention on their young as the smaller varieties do. The young should hence be zealously guarded the first few days, and as the doe is very easily angered very endeavour should be made to ensure quietness.—GETA.

FEED YOUR BEES.

ALL the bees in this neighbourhood are on the border land of starvation. I rode last Friday to the moor where mine are, and found several white drones put out of my large hives. I then went and examined the other hives in the vicinity of mine, and found the ground covered with young drones and workers. I called on the owners and warned them to feed at once, which several did. We have scarcely ever seen the sun for two months, and it has rained for four days incessantly, and while I write it looks as black as ever. All my hopes of honey for this season are gone, and I shall be glad if I can keep my stocks alive. Everyone should look to his hives on the moors and at home, and if he finds young brood cast out no time should be lost in supplying syrup, or they will have what I dread—that is, hunger swarms.—**HARDY OF THE HILLS, Northumberland.**

ITALIAN VERSUS BRITISH BEES.

I CONTEND that the Italian or Ligurian bee has not been proved to be better than our native bee—that is, better for honey-gathering, and the making of honey must be held to be the grand object of bee-keeping.

Ever since the discussion I had with my respected friend of Tillinamolt, New Pittsigo, in 1873, on this subject, I have paid special attention to the gathering of facts and theories from all sources, including the *Journal of Horticulture*, the *British Bee Journal*, and the *American Bee Journal*, with a view of adopting and keeping the best breed. Well, without any known bias to one species more than to the other, I have no hesitation in saying that the preponderating testimony in favour of the new kind appears to my mind to come from those who have them to sell.

Some parties buy a swarm of Italians, or a queen, and the first year they may or do excel our natives. To this I answer that the new queen is invariably introduced to the best hive in the garden, and if it be a swarm it gets extra attention.

Another person buys the new kind, and may have had them a dozen years, and when he had the old kind he never had such harvests of honey as now. To this I answer that apian knowledge is increasing, and that party must be considered to be much more advanced as a bee-keeper than he was ten or twenty years ago.

Various parties, forty or fifty miles distant, and at intervening distances, have applied to me for swarms of Italian bees. I have had to recommend these applicants to those who kept them. To those, therefore, who want the strange bee in order to sell at a big price, I say Get them, for therein appears to me the chief advantage. To those who want the new kind for their novelty, I say Get them; to those who want them for variety, get them, or for their beauty, get them, or who are careless for profit, get them, or whose hobby is bees, get them; but that they breed earlier, swarm oftener, fly farther, or fly faster, or work earlier or work later, or in colder or hotter weather, or are more docile, or gather more honey, or better honey, or live longer, or, in fine, are in every way more profitable, I do not at present believe.

My convictions are thus that the Italian bee is not superior to the British bee. To be candid, however, I have not learned any particular inferiority that they have, unless that many of those who keep them seem to have a deal ado with foul brood, the very rinderpest of bees. My contention is, that no person need be induced to pay a large price for Italians under the belief that they will gather more honey than our native bee.—**JAMES SHEARER, Cairnie (in Banffshire Journal).**

IPSWICH SHOW.—The Committee of this Show have decided to offer an additional class (82a), for "Any variety of Long-faced or Flying Tumbler," on my guaranteeing the first prize, and that Class 82 should now read, "For any other variety of Short-faced Tumbler." Entries close September 5th. Mr. C. H. Croydon, Ipswich, has kindly presented a special prize, value £3 3s., for the winner of most points in the Pigeon classes.—**H. W. B. BRUNO, Harwich.**

OUR LETTER BOX.

PRESERVING EGGS (R. I. S.).—Put them in some slacked lime just stiff enough to keep them in the position in which they are placed, then pour slacked lime over them till they are covered. Leave it till it is hard. Go on till the vessel (a bread or other pan) is quite full. The eggs should be put small end downwards.

CHICKENS CRAMPED (J. Ll.).—Give them bread soaked in ale once daily, and do not let them out until nearly mid-day.

LINNET FEEDING (Lady Sybella).—Millet seed is too fattening. Canary seed is far better. Give occasionally chickweed, shepherd's purse, and plantain seed.

RABBIT-KEEPING (A Young Rabbit-keeper).—Give the bran dry, and lettuce leaves. Buy our "Rabbit Book;" you can have it free by post if you enclose eight postage stamps with your direction.

BOARDS SUBMERGED (Salop).—A glue that will resist the action of water is made by boiling 1 lb. of common glue in two quarts of skimmed milk.

BUCKWHEAT (S. W. T. K.).—The time for sowing is May, and it is usually fit for mowing and thrashing in October.

BEES UNDER A FLOOR (E. R., York).—It will require the skill and courage of a bee-keeper of experience to remove the two swarms that entered by the air grids and settled between the joists of your chamber floors. If the boards are taken up, be prepared to apply large doses of smoke from fusian rags wherewith to frighten and master the bees. Let the swarms be deluged with smoke, then cut all the combs from the boards and place the brood combs on boards or pieces of calico with hives over them. The bees will soon find the brood combs and settle amongst them, when they could be removed to the garden. All the air grids should be closed for a month to prevent the bees from returning to the house again. A few days after the bees have been placed in the garden the swarms should be united in an empty hive, and fed into a good stock.

DRIVING BEES (Novice).—The advice already given to you is all that is needed. No biter can be given. The one hive driven has been found worthless; the other may not be so, and should be driven as per advice.—**A. P.**

UNITING BEES (W. B.).—In uniting the swarms it would be better to kill the older queen, but if both swarms with their queens be cast together the bees will destroy one of the queens. You are quite right in fearing that the bees, now 200 yards from your garden, would return in considerable numbers if they were removed at the present time. Could you not find some place about a mile further off, where they could be fed every night for a fortnight? After a month's absence from their present locality they could be safely placed in your garden, or they could be fed into a stock in the cottager's garden and remain there till January next.

METEOROLOGICAL OBSERVATIONS.

REMARKS.

22nd.—Rain in night and early morning; fine at 9 A.M., some showers, but on the whole a pleasant day, the air so fresh and cool; a most splendid moonlit night.
23rd.—A fine fresh morning, very bright day though much cooler; scarce any cloud at night, so the eclipse seen very well from first to last.
24th.—Fine bright day, but not quite so fresh-feeling as yesterday; slightly hazy at night.
25th.—Rain more or less all day and night; rain at times, heavy thunder storm about 2 p.m., and another in the evening, the lightning very vivid.
26th.—Calm grey and warm morning, fair but dull all day; rain after 10 p.m.
27th.—Regular wet night, morning, and forenoon; fair but dull afternoon and evening.
28th.—Wind and rain in the night, rain till nearly noon; after that time bright and fine.

A great fall of rain during the week and absence of sun has lowered the temperature considerably, making rather more than 7° below that of last week, and in the max. in sun 17°.—**G. J. SIMONS.**

COVENT GARDEN MARKET.—AUGUST 29.

THE only home produce now arriving of any consequence is Apples and Nuts, for which there is a fair demand, otherwise the market remains very dull.

HINTS ON HARDY FRUIT CULTURE.

GARDEN without fruit, and plenty of it, is unworthy of the name; it is a source of vexation rather than of pleasure—occasions much disappointment to its owner and of some to his friends, the pleasure of whose visit is wonderfully enhanced by the enjoyment of a juicy Peach or other fruit which may be in season.

I know full well that failures but too frequently spring from causes beyond our control. Cold cutting winds, untimely frosts, hailstorms, and dull, cold, wet weather when the blossom expands, are all sources of mischief hard to encounter and difficult—often impossible—to overcome. But when the difficulties are grappled with as they best may be, and due care and skill are devoted to each process of culture, not a year will pass without some success.

This year we have had abundant crops of Strawberries and of bush fruits; Nuts are plentiful, and some few varieties of Pears and Apples are laden with fruit. Next year, with a favourable spring, we may hope for fruit of all kinds in abundance after this season of rest, so favourable to the formation of strong plump fruit buds.

Before planting fruit trees of any kind weigh well the requirements of your family, your own tastes, the space at your disposal, and your ways and means. Avoid anything like a collection unless you possess an almost unlimited amount of space; rather select a few really good sorts and try to cultivate them well. Avoid crowding; never forget that a large tree will bear more and better fruit than half a dozen small trees. Do not let the term "large" mislead you, for I do not refer by it to the huge standards of orchards but to garden trees; and if your garden is small, far better would it be to have a fine pyramidal tree at each corner of the quarters, or at intervals of 10 feet, than to have a crowd of scrubby dwarfs, stunted, unhealthy, unsightly, and bearing some half dozen, or may be a dozen, under-sized fruits—a miserable return for all your pains and care.

The very best plan for a small garden is to plant pyramidal trees at the corners of the quarters with espaliers trained as palmette verriers along the sides, thus securing economy of space with strong free-growing healthy trees.

Whatever may be the system of culture you adopt master it thoroughly, and then carry it out in its fullest integrity. If you wish to indulge in a few fanciful forms of training take care that such training is well done, and do not forget before turning your hand to it that such work requires much attention and occupies considerable time, or failure total or partial will be the inevitable result. Let me earnestly urge upon the attention of all having the care of young trees to endeavour to make every tree a good model; you will not succeed in doing so with every one of them, but you will succeed in producing well-formed trees, erect and well-proportioned, pleasant to behold even when not laden with fruit. Nothing affords me greater pleasure when visiting a

garden than to be taken among the fruit trees, to have the manipulations of the pruner and trainer with its end and aim explained to me, and thus to find an intelligent method of culture united to painstaking and care.

This attention to young trees is a matter urgently demanding much more prominence than is usually given it. The young pliant growth will take any form, follow any direction we may choose to impart to it; but if carelessness and neglect once sets its stamp upon a tree, its traces can never be effaced by any subsequent efforts however skilful they may be.

That fruit trees are much neglected when young there can be no doubt, the leaning grotesque forms to be met with in so many gardens affording ample proof that it is so. Why is this? I cannot suppose it is owing to carelessness or ignorance, but rather to want of time on the part of those having the care of them; and I would urge upon gardeners the importance of pointing out to their employers the irreparable mischief which must follow neglect, and I would also press upon employers the important fact that a new garden requires more labour power than an old one. Every part of it and everything in it, especially the fruit trees, demands, and must have, an extraordinary amount of attention; and if the gardener fails to obtain an adequate amount of assistance something must be neglected—usually the fruit trees, for the flower and vegetable supply must be kept up to meet the daily demands.

There is one important point nothing should be allowed to interfere with, and that is the planting: only do this well, and if the trees are somewhat neglected they are not likely to suffer in health. By planting well I mean that there should be at least 2 feet of good soil below the roots of the young tree, and that soil should rest upon 6 inches of stone or other hard substance—an admirable plan practised by our forefathers to prevent the roots getting down to the till. Each station of this good soil should therefore be 2 feet deep by 6 feet square, and drains should be made if there is the slightest risk of any accumulation of water about the roots.

The soil of old gardens contains so much humus—vegetable matter—that when replanting it with young trees it should have an abundant mixture of lime and rough gritty matter; if this is done, and it is thrown up roughly to be sweetened by the air some time before planting is done, nothing more is necessary, and the trees are quite certain to grow satisfactorily.

I have the greatest respect, or rather veneration, for old timber trees and would not lightly remove one of them, but I never would retain a worn-out old fruit tree, for nothing can be more unsatisfactory. Take, for example, an old Peach tree. Why do you keep it, or rather why do you retain its old branches? "Because it is still fruitful," do you say? Yes. So it is, but what sort of fruit does it bear? Would your best dozen win a prize? I trow not. Cut it down, and if it put forth young vigorous branches, as is not unlikely, then let it remain, and you will obtain prize fruit and plenty of it; but if it fail to grow again strongly and well then up with it, for roots

as well as branches have done their work, and a young tree must take its place.—EDWARD LUCKHURST.

AURICULA NOTES.

SOME correspondence has appeared lately in your columns which induces me to take up a pen to champion my favourite flower. I do not think the *Auricula aphid* is such a formidable enemy as "D., Deal," has hitherto found it, and I venture to prophesy that if he deals with it as promptly as he is now doing it will sink into the category of a second-rate foe, to be kept at bay by watchfulness in the same way as the green aphid is. It is the loving watch upon your plants that gives you early information of coming mischief, be it damp, aphid, or rot in the calk, and early information enables you to apply that early remedy which alone will save so sensitive and refined a plant as an *Auricula*.

I have the *Aphid Auriculæ* still upon my plants, but in restricted numbers, and I am watching them closely. As I promised early in the year, I quarantined some infested alpine, but the aphid has not thriven upon them, from which I infer he dislikes the disturbance entailed by the necessary moving each time an observation is wanted. Does not this teach a lesson?

It has re-appeared upon some of the plants which were cleaned with care in February, washed—foliage, calk, and root—in soft soap and water, and repotted, and then repotted a second time in May or June when they were clean, but it is strongest on some few plants which, owing to their bearing seed, were isolated, not repotted in June, and on which I am now watching them. All this seems to show one dose may not be enough, the watch kept must be renewed, and if necessary the treatment be repeated.

I am now using Gishurst compound, of which I mix 2 ozs. in one gallon of water and let it stand a few hours, and am not afraid to dip the plant in—pot, roots, leaves and all; though, of course, with the mealy-foliaged plants a more delicate operation is required, and the foliage must be exempted from so drastic a treatment. I find no harm to result but rather good, and my gardener, Robert Stafford, declares the plants directly benefit from the Gishurst, an opinion to which I scarcely like to stand godfather, though I am watching to see, and am convinced of its benefit indirectly in its effect upon insect life. The large bulk of my collection is clean, a small quantity of aphid only having made its appearance on plants repotted in June, but still enough to require watching. It would be interesting to know if other people's experience in any way coincides with mine.

This year I had the pleasure of blooming my first seedling *Auriculas*, chance-saved seed from my own flowers. And what a pleasure there is in a bed of seedlings! It is a lottery in which you draw all prizes and no blanks. Every day discloses some new beauty, and you know that your plants have all the vigour and health of their whole life before them. But though it is all gain and no loss, the great prizes are very few in such a lot as I describe. The seed was saved from good flowers. *Privater* (Grimes), *Ringleader* (Kenyon), *Colonel Chamneys* (Turner), *Lord Lee* (Berry), *Mary Ann* (Fletcher), *Empress* (Turner), *Eliza* (Stims), *Mrs. Smith* (Smith), &c.; but not crossed carefully with selected pollen parents, the fertilisation was a matter of chance, and as prophesied twelve months ago by the Rev. F. D. Horner, what wonder that the quality was inferior? To a florist the lot showed every fault to which the *Auricula* is subject. To others their brilliance and exquisite scent commanded the admiration of all who saw them. To me they were a source of constant delight and wonder. Why should *Empress*, for example, give me first a really good alpine firm and rich with its dense yellow paste, second a grey edge resembling *Conqueror* of Europe, and third a rich dark self only spoilt by a wavy paste? and why side by side should *Fletcher's Mary Ann* give me a lovely deep violet self, and then a white edge of good proportions and quality spoilt by a staring pin eye? The very disappointments of the lot were delightful in their provoking variety; every fault, nearly every virtue, were blended in indescribable confusion, but the bloom passed away and has left the memory of the most charming flower bed I ever enjoyed, and a little experience of failure by which I hope to benefit in future in a more careful selection of seed, which should give a larger per-centage of those good qualities which make one variety better than another.

Before I close my notes may I ask your correspondents if

they know any larger yellow alpine *Auricula* than *Primula auricula*? Years ago I found in the high Alps of Switzerland, under a high overhanging cliff facing the north where the sun seldom struck, the largest and richest *Auricula* I ever saw, the flower stem from 9 to 10 inches, with eighteen pips of large yellow flowers, and the whole plant richly dusted over with white farina. I can scarcely think it is the *Primula auricula*, which is now a garden favourite, and which thrives well both in pot and open-air border with me, but which when in its finest health and condition never approaches the lusty giant I remember, and which I hope some day again to search for on the St. Gothard.—JOHN T. D. LLEWELYN.

WINTER CUCUMBER CULTURE.

CUCUMBERS, like many other garden products, appear to be valued just in proportion to their scarcity. If by some slip of the tongue of an assistant an idea becomes settled in the kitchen that Cucumbers are scarce in the garden the kitchen people will become especially alive to their importance, and every order sent to the gardener will begin with Cucumbers. If there is one season more than another when Cucumbers are really scarce, and at times especially valued, it is during the months of December, January, and February. I have generally passed through these months tolerably comfortably by commencing preparations in good time and thus mostly avoided any serious scarcity, and, if scarcity at times has occurred, by keeping as much as possible the knowledge of that circumstance to myself.

Cucumbers for fruiting during the winter should be planted at once, and the plants should be strong to begin with. I sow the seeds during the last week in July, and grow the plants under the influence of all the light and air they will endure, with the object of producing woody stems and medium-sized thick leaves—not large flabby foliage.

It is no use attempting the growth of winter Cucumbers unless well-heated houses are provided, I mean houses containing a sufficient amount of piping to preserve a night temperature of 70° in severe weather without violently heating the pipes. That temperature may not always be required, but it is none the less necessary that the pipes should be able to produce it. Overheated pipes promote red spider, weakly growths, and deformed fruits.

In addition to pipes for affording bottom heat I like a good quantity of dung and leaves, and the Cucumbers like it too. A bottom heat of 80° to 85° is a suitable temperature for the roots.

Soil, of course, is important. It should be fresh, good, and rough. Chopped turf just blackened with soot I have found suitable; if at all poor, one-third of horse droppings—old mushroom-bed manure—may be mixed with the loam. A great bulk should not be employed at once. Commence with a small hillock for each plant, and surface-dress weekly or whenever roots protrude and ask for fresh food. Active surface roots induce healthy fruitful growth, and open—previously warmed—turfy soil and warm water secure active roots. Water must be given according to circumstances. It must at all times be sufficient, at no time excessive.

Temperature, ventilation, and atmospheric moisture are important elements in winter Cucumber culture, and not much less important is bright clean glass. A night temperature of 65° is a safe one, with just a chink for air in the top ventilators. During very severe and also dull weather the thermometer may fall to 60° at 6 A.M. The day temperature should be 5° or 6° higher by fire heat, and should reach its maximum at 9 A.M. That is important. The sun heat may rise to 80° to 85°. Watch for this, and bottle it up by early closing; it will save coals and produce green foliage (which red spiders do not appear to like), and green Cucumbers too, which look well anywhere—on the plants or the table. As the temperature increases so let the moisture increase; this will be insured by the troughs on the pipes when the heat is from the fire alone, but with sun heat the walls and paths occasionally need damping. Syringe on favourable occasions. The water must not hang about the plants during hour after hour. One good syringing weekly is more effectual than daily squirts. Prevent red spider if possible. Perfectly clear soot water is a deterrent; it is also stimulating to the plants.

Great watchfulness of the weather at night, early morning attention, cautious admittance of air, intelligent guidance of heat and moisture, are the chief essentials to success in winter Cucumber culture. A trio of excellent sorts are *Telegraph*,

Lord Kenyon's Favourite, and Munro's Duke of Edinburgh.
—A RETIRED GARDENER.

A GOOD SUMMER APPLE.

IN the last volume of the Journal (pages 226 and 267) I mentioned an unnamed early Apple. I now send some fruit for your examination. I have had a very good crop on my tree this summer, notwithstanding the unfavourable season for most other sorts. In the spring this variety gave a succession of blooms extending over a long period of frosty weather; the last blooms, however, had a few fine days to set the pollen, and so a crop was saved. By the way, all my varieties which have this habit of long succession of blooms are bearing heavy crops, such habit being, I consider, of great value in an Apple, giving the variety a good chance of escaping the spring frosts which readily kill the pollen, while such a variety as Scarlet Nonpareil, for instance, which has all its blossoms out at once, has but one chance in the season.

Fig. 42.

But to return to our Apple. Its refreshing juice has been very welcome during the hot weather, a rich perfume and handsome appearance being among its attractions. In regard to its ripening period I have had it ripe in the middle of July in former seasons, but this year it was not ripe till the end of the month, in consequence, I suppose, of the failure of the first blossoms and the backwardness of the season. My ground will not produce early crops, and the tree is in a cold place partly shaded, and is on a deep-rooting stock.

I cannot say what would be the result of grafting on the Paradise stocks and planting on a warm soil, but I certainly must call this a very early Apple. I have some dwarfs on Rivers' Nonsuch Paradise stocks, and intend to try a better soil and position.

I do not know the origin of this variety. I purchased it among some unnamed trees and plants of a nurseryman, who believes that the Apple tree came from Norfolk. It has a drooping habit of growth, and would therefore not make a good pyramid.—W. GROVES, *Shortlands, Kent.*

[Fruit small, of the size and shape of Early Red Margare but not so distinctly striped as that variety; conical, with obtuse ribs on the sides. Skin smooth, covered nearly all over with a dull livid red, which is marked with crimson stripes on the side next the sun, and on the shaded side it has a greenish-yellow tinge mixed with the red. Eye with erect somewhat divergent segments, set in a narrow basin. Stalk short, about a quarter of an inch long, inserted in a pretty deep cavity. Flesh pale yellow, tinged with green just before it ripens, but becoming quite yellow, firm, very juicy, and with a brisk aromatic flavour. Cells closed. Calyx-tube funnel-shaped. Stamens median. It belongs to group 30 of Dr. Hogg's New Classification of Apples.

The fruit is remarkably fragrant, and as a good market Apple we cannot suppose any to be more attractive.]

MILDEW ON ROSES.

CAN and will any of your experienced Rose-growing correspondents tell me what will prevent or cure mildew on Roses? I

am utterly baffled by it, though I am familiar with Rose culture from long practice and the frequent perusal of all the best treatises on the subject, and also all that is said in "our Journal;" therefore merely referring me to sulphur is useless.

The soil is stiff loam mixed with stones and corks with hot sun and drought, the situation near Barnet, ten miles north of London. Roses grow here after pruning in April with marvellous vigour until the flower buds are many and large, but then there seems a halt, and full Roses, like Duc de Rohan and Madame Victor Verdier, this year and last, open badly or not at all, and with brilliancy of colouring gone.

After the first flowers are past and growth begins again mildew appears and is irrepressible. I have tried removal or transplanting, also leaving the trees in one place for some years, also with rotten manure below the roots, and planted without, with mulching, and with merely hoeing, but all mildew as I have described above.

Now, what is the remedy? for I have both watered and left others unwatered, and as yet have not found a cure for the pest.—S. S.

THE POTATO DISEASE.

ALTHOUGH several writers, myself amongst the number, have recommended the lifting of Potatoes immediately they have ceased swelling, even if the haulm were still green and the skins of the tubers not set, no one that I am aware of has advised their removal from the ground when the tubers were only half swelled, as implied by Mr. Muir on page 172. That tubers will keep well when dug in an unripe state I have, besides my own experience, the evidence of such cultivators as Messrs. Luckhurst, Abbey, Gilbert, and Wright. I know the tubers will not only keep well, but will mature as well out of the ground as in it, and will become of splendid quality if they are properly managed. I think I know a good Potato when it is cooked, and I can assure Mr. Muir that I had Victorias last year which were lifted when the haulm was still green, and when the skins ruffled with the slightest touch, which were of splendid quality throughout the winter. Mr. Muir conveys the idea that tubers thus lifted are "never good for food;" he should have said never as he manages them. It is not necessary to repeat the right mode of management; Mr. Luckhurst has recently stated the system fully and well, and I can vouch for it that the plan he described is safe, sound, and certain. If the tubers have ceased swelling they may be taken up, and they will mature as well out of the ground as in it, and often very much better. Mr. Muir also states that tubers when taken up in an unripe state are "not fit for planting anywhere." He is in error there. I have tried them for ten years consecutively with the special object of testing the point, and the stock which has been so treated is as productive now as ever it was, and I believe as any Potatoes possibly can be. I care not what theory is advanced to prove that this cannot be the case when I have the fact before me that it can and is.

It will not do to let the haulm remain to be blackened before the crop is dug; but if the tubers attain a full size before the malady affects the haulm, and the crop is then taken up, it is safe. I agree with Mr. Muir that if the crop is actually diseased it may as well remain in the ground as be piled in heaps above it. I agree with him also that "wet weather is the sure propagator and promoter of disease." On this point a recent visit to London has enabled me to obtain the best evidence on that point that I think has ever been placed before the public. I am indebted to Mr. Wright for what I am about to submit, and why it has never appeared before is to me not a little surprising. The compiler of the following table, which must have cost a considerable amount of labour, has evidently never been at a loss for a subject to write about, or he would not have kept the matter in his desk for four years. However, it is at my disposal now to do as I like with, and my decision is to send it to the Journal, where it ought to have been before. It was in combating some vague electricity notions that I advanced in conversation that the proof was adduced that excessive wet is the real cause of the Potato disease. I will now append from what Mr. Wright has placed in my hands.

"Heavy and continuous rain in the warm summer months," he has written, "is the primary cause of the Potato disease. Other contingencies have their effect, but summer rain falling in extreme quantity is the great disease lever and governor. The overpowering influence which rain exerts in connection with this perplexing visitation is strikingly demonstrated in

the following table. It extends over a period of thirty years known as the disease period, computed from the fell outbreak in 1845 to the close of 1872. The relative amount of disease in the different years is the result of personal observation, confirmed by other observers in the same district who have given special attention to the subject. After the relative amount of disease in the different years had been determined (not before), the monthly rainfall in the same district was obtained. It was kindly furnished by careful collectors of rain of established reputation—the Rev. J. E. Cross of Appleby Vicarage; A. S. L. Melville, Esq., of Branston, Lincoln; and G. J. Symons, Esq., the eminent meteorologist of Camden Square, London. The first attempt to elucidate from the somewhat formidable array of figures a principle of Potato-disease governance was a failure. The gross average annual fall of rain and the average of each year separately were first taken, assuming that in proportion of each to the whole so would the proportion of disease be. But on this no reliable data could be founded, and for a very good reason, that the rains of winter have no connection with the matter of the summer malady. The next procedure was to prove the thirty years' average of the amounts falling in the Potato-growing months, April to September, both inclusive. This proved itself 13.30 inches. On finding the amounts of the same years separately, and noting their relative proportion with the gross average of the whole, the plus + and minus — show, not quite with unerring exactitude, but in a very remarkable manner, that the ebb and flow of the disease float with what may be called the ebb and flow of rain in the same years and district.

"The extent of the disease is divided into three general and intelligible classes, prefixed by the years of 'no disease,' followed by 'slight disease,' 'decided disease,' and 'great disease.' The amount of rain in the six months is given on the same line as the year, together with the excess or deficiency in relation to the general average, which is also stated at the top of every alternate column. Take, as an example, the second year named. It is 1854 in the 'no disease' column. The quantity of rain for this year in the six months, April to September, is 9.32 inches. This is 3.98 inches below the general average of 13.30, and is so signified by the minus sign —, excess being signified by the plus sign +. The table quite removes the paramount influence of rain from the category of conjecture in seeking a cause for disease-outbreaks, and places it as a fact demonstrated; and it will require argument of extraordinary subtlety to reason away the position, that the first great acting cause of the Potato disease is excessive rain falling in the period of growth, and especially at the juncture when the plant is on the eve of ripening.

"The table, however, shows a few, very few, failing points on the face of it. It would have proved the position still more clearly had April been excluded and October added. It would, moreover, have been perfectly fair to have adopted this arrangement, seeing that the month of April can exert no practical or immediate influence on the spread of disease, while October certainly does so occasionally, although not to a serious extent. The theory, however, shall not be strained, but shall stand on its merits as originally compiled.

"But the apparent weak points of the table will bear examination. Let us glance at them. It appears, then, to be at fault inasmuch as the 'no disease' year of 1867 shows an excess of rain of 0.14 inch above average, while the 'decided disease' year of 1852 shows a deficiency of 0.39 below average. First referring to 1867 and its seeming excess we find that it was contributed by April, May, and June (which affects the disease only slightly if at all), averaging 2.53 inches; while the latter three months—July, August, and September (which are of supreme moment in fostering the murrain), gave an average of only 1.94 inch, which is really not an excess at all, in the disease-producing months. With this examination the apparent error vanishes. Now let the 'decided disease' year of 1852 with its 0.39 deficiency be placed in the crucible. The first four months—April, May, June, and July—only gave a rain average of 1.94, while the two months following—August and September—averaged not less than 3.19 inches, the amount for September being 4.16 inches. This influx, coming at a critical time, accounts for the mischief which the four fine months preceding could not avert. Again, 1847, a 'slight disease' year, shows an excess. This excess is contributed by May and June, which averaged 3.75, the remaining four months averaging only 1.31 inches. The disease showed itself this year very early and again subsided. The same may be said of 1861–2, and are marked 'E' to distinguish them. That the amount

of disease is not expressed by the figures in exact gradation and with mathematical accuracy may be accounted for by the local nature of rain, especially thunderstorms and other contingencies, such as cloud and temperature. What differences there are, are therefore essentially due to local and varying influences, as limited (in area) thunder showers, and other circumstances such as varying cloud, atmospheric moisture, and temperature. Such, however, do not materially weaken the remarkable proof the table gives as to the pre-eminent power of excessive rain as the great foster-parent of the devastating Potato murrain."

AVERAGE OF HALF-YEARLY RAINFALL
OF THE POTATO-GROWING MONTHS APRIL TO SEPTEMBER INCLUSIVE, 1844 TO 1873,
WITH FLUCTUATIONS AND THEIR INFLUENCE ON THE POTATO DISEASE, THE AVERAGE RAINFALL FOR
THE ABOVE PERIOD AND MONTHS BEING 13.30 INCHES.

Years of No Disease.	Rain from April to Sept. and re- lation to average of 13.30 inches.	Years of Slight Disease.	Rain from April to Sept. and re- lation to average of 13.30 inches.	Years of Very Decided Disease.	Rain from April to Sept. and re- lation to average of 13.30 inches.	Years of Great Disease.	Rain from April to Sept. and re- lation to average of 13.30 inches.
1844	10.20 — 3.10	1847E	13.75 + 0.47	1846	14.50 + 1.20	1845	15.50 + 2.10
1854	9.32 — 3.98	1850	11.61 — 1.69	1851	13.33 + 0.03	1848	18.45 + 5.15
1855	10.25 — 3.05	1853	10.88 — 2.42	1857	15.18 + 1.88	1849	16.00 + 2.70
1858	9.63 — 3.67	1856	11.62 — 1.68	1852	12.91 — 0.39	1860	16.78 + 3.48
1864	8.94 — 4.36	1861E	10.79 — 2.51	1866	14.95 + 1.65	1871	16.94 + 3.64
1867	13.44 + 0.14	1862E	13.04 — 0.26	1859	13.94 + 0.64	1872	17.93 + 4.63
1868	7.68 — 5.67	1863	11.47 — 1.83				
1870	7.72 — 5.58	1865	12.09 — 1.21				
		1869	12.35 — 0.95				
		1873	11.97 — 1.33				
8		10		6		6	

I have nothing to add to the above table and remarks, but I may at some future time make further extracts from the notes which have been placed in my hands by one who has evidently given much attention to Potato cultivation and disease.—
A NORTHERN GARDENER.

ROSES IN NORTH WALES.

As you have had "Notes on Roses" from South Wales, I thought perhaps a few jottings thereon from North Wales would not be unacceptable, particularly as these come from a high elevation—nearly 700 feet above the sea level. To begin, at the time of the grand National Rose Show we had not a bloom out, so that we had to be content with the very full description given by "WYLD SAVAGE" in this journal. We do not grow a large collection here (some two hundred plants or thereabouts), but as our situation is high and exposed I thought probably the sorts that do well here might be useful to some of your readers who are similarly situated. The majority of them are budded low on the Manetti; I have also a few on the Briar, which do very fairly on our soil—a medium loam. The sorts which have succeeded best here are Marquise de Castellane, very large and fine; Lyonais, Mdle. Marie Finger, Maurice Bernardin, Miss Ingram, Lord Raglan, Fisher Holmes, Baron A. de Rothschild, Baronne de Rothschild, François Michelon, Baronne Prevost, Jules Margottin, John Hopper, Lord Clyde, Olga Mariz, Baron de Bonstetten, Abbé Brammerel, Ferdinand de Lesseps, and Princess Louise Victoria. These do best in our exposed

climate, though we have many other first-rate sorts that I have noticed succeed well in more favoured localities. Of Tea Roses we have only a limited number as yet, and I have not tried them sufficiently to speak with confidence as to their capabilities for standing high elevations. The cultivation I adopt for Roses is the same as "A RETIRED GARDENER" recommends in the vegetable garden—namely, a plentiful supply of manure both in the solid and liquid form, and their healthy appearance tells me as plainly as words how much they like it.

I wish I could say the same as regards Pierre Notting being a good autumn bloomer as the "WYLD SAVAGE" does. With me it positively refuses to open, owing, I suppose, to the continued rain which we have had almost daily.—AN ENGLISHMAN IN WALES.

CARLISLE.

"How fair, amid the depth of summer green,
Spread forth thy walls, Carlisle! thy castled heights,
Abrupt and lofty; thy Cathedral tower
Majestic and alone; thy beauteous bridge
Spanning the Eden, where the angler sits
Patient so long, and mark the browsing sheep
Like sprinkled snow amid the verdant vales."

CARLISLE, says the author of Arthur's "Guide" to that city, is one of the oldest, and at the same time one of the newest, of cities. Its foundations speak of Roman conquest and Roman civilisation and refinement. Its chief buildings are monuments of mediæval art. The greater number of its houses, its churches, and its chapels have been erected within living memory. It has a population of more than thirty thousand inhabitants. It is the border city on the great trunk line of rail which has the metropolis of a kingdom at either end. It is encompassed by three rivers—the Eden, the Caldew, and the Petteril—and it has, therefore, been aptly called "the City of the Water." The scenic beauty unfolded from its heights can hardly be surpassed in extent, variety, and grandeur. Built upon a hill which its walls once enclosed, but which would now shut-out its most populous suburbs, it commands a prospect only limited by the lofty mountain chain that encircles the great basin in which Cumberlands lies. From the summit of the Cathedral, or from the tower of the Castle, the eye sweeps without interruption a vast landscape—rich in wood and water and fertile valleys—over which the light and the shadow alternate, and the seasons spread their variegated hues. Southward, over these sunny fields and dark woodlands the majestic Skiddaw rears his noble crest, and Helvellyn his wedgelike peak radiant with the first and last rays of the sun. Saddleback and the lesser hills link the apparently unbroken chain with Crossfell and the eastern range; while further to the left the Northumberland fells bound the horizon. Then come the uplands by Bewcastle and the border, and the pastoral Cheviots, "Scotia's southern bound." Away round to the west, the magnificent belt is terminated by Criffel, standing in solemn grandeur above the Solway.

"'Tis a prospect fair—of river, wood, hill, and vale,
As ever eye could wish for."

A few notable places (horticulturally) surrounding the city have been mentioned, and more extended notes of two of the chief nurseries may appropriately be published.

THE KNOWEFIELD NURSERIES.

These nursery grounds, which belong to Mr. Baxter Smith and Mr. James Watt, the partners of the old-established firm of Little & Ballantyne, occupy 130 acres, have been most happily chosen for situation, quality, and variety of soils. The site is directly north of the "merry city," on an open and elevated situation. Fewer hedges are seen here than in most nurseries, which is considered a great advantage to hardy trees and shrubs, particularly in reference to late spring frosts. The young wood is also much stiffer and better matured, and is preferred both for home and foreign trade. The grounds are within ten minutes' drive of the central station, and well repay a visit. The carriage entrance is very beautiful, and the borders, for above a quarter of a mile in length, are planted near the margin with a choice collection of ornamental evergreen shrubs, Conifers, Rhododendrons, Hollies, &c., backed-up with fine specimens of weeping and other trees suitable for immediate effect. The broad belts forming the background to these borders furnish great variety both of form and habit, and some striking yet pleasing combinations, as, for instance, when the golden and black-leaved Oaks are planted side by side and backed-up with the Silver Poplar, or when the Lime in one or other of its forms is grouped with contrasting forms,

like the Oak, the Mountain Elm, the Aspen, the Ash, or the Plane. Specimens of all sizes, from 3 feet to 20 feet or more, of the greater number of hardy ornamental trees are planted-out here, in order to give some idea of the effect which the same kind of tree produces in different stages of growth, and in different combinations with other kinds—considerations of some importance, which are too apt to be overlooked in making arrangements for permanent plantations. Among shrubs the following are especially worthy of notice—viz., *Berberis vulgaris atro-purpurea*, the dark purple-leaved Barberry; *B. stenophylla*, a hybrid between *B. Darwinii* and *B. empetrifolia*, possessing the flowers of the former with a habit and hardiness superior to it. Azaleas of the Pontica and Ghent sections exist here in great variety, as do also Rhododendrons, Heaths, Hollies, Gaultherias, Andromedas, Kalmias, Sedums, and Spiræas, among which latter *S. Fortunei*, a very dwarf white-flowered sort, is one of the best.

At the top of the Avenue, on the right, is the pinetum, in which specimens of all the really hardy Coniferae at present in cultivation are gathered together. The situation chosen for testing these important classes of trees is one of the best that could be found for the purpose, being high and fully exposed to all the points of the compass; so that if any sort is found tender here, it cannot with confidence be recommended for any colder locality or situation. The collection embraces all that is worth growing among the really hardy kinds, while those that are found fit only for the most favoured localities find the necessary shelter and protection in pits and in closely hedged quarters. The most remarkable for robust health and fine form in the pinetum are *Piceas lasiocarpa*, *magnifica*, *Parsonsi*, *nobilis*, and *grandis*; *Pinus Murrayana*, *ponderosa*, and *Jeffreyi*; *Cryptomeria elegans* and *Lobbi*, *Balfourii*, &c.; *Wellingtonia gigantea*, and its variety *pendula*—a handsome form of the Mammoth Tree, which originated in this establishment a few years ago. It is a striking variation from the style of the ordinary form of the *Wellingtonia*, the branches and branchlets being quite pendulous, and consequently more graceful than the massive yet elegant original, and will be sent out by this firm for the first time in the autumn.

Turning from the pinetum to the left the main block of houses forms the background to the view in that direction, and the foreground consists of a flower garden in grass, surrounded on three sides by borders of ornamental shrubs. In borders in the neighbourhood of the flower garden is a collection of Hollies in all the most popular and effective varieties.

In one of the borders near the house stands the original tree of the Knowefield Tricolor Beech. This is a new form of Purple Beech, the leaves of which are boldly margined with silver, and strikingly flamed and pencilled with brilliant crimson on a dark coppery ground colour. Near by stands the original of another Knowefield production, the black-leaved Oak, the best of all the dark-leaved Oaks, which, though well known to connoisseurs of hardy ornamental trees, is by no means so generally known as it deserves to be among those who have most to do with plantations practically.

As regards the plant houses, they are admirably arranged and well adapted for the purpose of plant-growing, and are stocked as one would expect to see a well-appointed nursery with classes of plants in most demand. There are about 500 feet of glass, with innumerable pits or cold frames, covering altogether nearly an acre of ground.

Roses are a decided speciality of this establishment—a fact that strikes the visitor forcibly when he finds himself in the midst of the wide-stretching quarters devoted to their culture. Some idea of the importance and extent of this department may be gathered when it is stated that upwards of fifty thousand standard and dwarf Roses are grown annually, to meet the ordinary demands of customers in this country and in America.

Fruit trees, too, are grown very extensively, from eight to ten acres being devoted to their culture; and the general nursery stock of transplanted and seedling forest trees and shrubs is also very varied and complete.

Forest trees are also a great speciality of this nursery, which is simply a plant factory, turning out every season immense quantities which are sent all over the kingdom.

The seed department is conducted at present in English Street and Blackfriars Street, where the firm has for nearly half a century carried on that branch; but increasing connection has necessitated their moving to larger premises, and there is now in course of construction a handsome block situated in the most prominent part of the city, to which they

will shortly remove. When completed this will certainly be one of the finest buildings in the city, and being of the native stone it is much admired, being from plans by the diocesan architect, and is a mixture of Grecian and Scotch baronial architecture.

STANWIX AND HARRABY NURSERIES.

THESE belong to Messrs. Clark Brothers & Co., and are five and twenty acres in extent respectively. The first-named is reached from the city by crossing the bridge over the Eden, and is three-quarters of a mile from the Town Hall. This nursery has only been opened about six years, but is now established. It contains a miscellaneous nursery stock, principally, however, of Roses, fruit trees, and Conifers, which are in excellent condition. Rhododendrons and all American plants are in robust growth without any addition having been made to the soil. The main feature on entering the grounds is the centre walk, running directly down to the extreme end of the nursery and curving round the centre conservatory, which is placed so as to be the prominent object at the end of this walk. This walk is bordered with Conifers, shrubs, &c., and contains good examples of *Pinus nobilis*, *P. Nordmanniana*, *P. Pinsapo*, &c.; *Cupressus* of sorts, very prominent for beauty being *C. erecta viridis*, of upright habit with dense dark green foliage; *Wellingtonia gigantea*, *Theopopses* of sorts; *Cryptomeria elegans*, which is here quite hardy and much admired for its distinct habit of foliage from all other Conifers. *Taxus aurea variegata* is this season very bright, and makes an effective contrast in a mixed border. Hybrid named Rhododendrons grafted on tall stems are here planted down the border, and in spring when in full bloom are very beautiful. Two specimens of the weeping common Holly, one on either side, attract notice: when in full berry they are very conspicuous and beautiful. *Acer Negundo foliis variegatis* contrasts well with the green of the evergreens. There are also many good forest trees, some being thinly planted and have well-shaped heads. The other parts of the nursery are laid out in the usual squares and filled with variegated and common Hollies, hybrid Rhododendrons, common and Portugal Laurels, common and Irish Yews, &c. The Colchican Laurel grows very luxuriantly and has not yet been injured by frost. This is due to its habit of ripening-off early, in this respect differing from the common Laurel, which is apt to make a late autumn growth which the frost very often cuts down. *Rhus laciniata*, dwarf in habit, is noticeable; and *Ligustrum ovalifolium aureum variegatum* is very bright, and is suitable for town-planting.

Fruit trees are grown as standards pyramid and dwarf, trained and untrained.

Roses are also largely grown, and owing to the International Flower Show have been subjected to a system of disbudding which promises to be a success. All the Roses worthy of cultivation are propagated. Dahlias are also largely grown, new varieties being added yearly. Pansies are carefully grown, and hardy Lilliums are blooming abundantly.

Among herbaceous plants Delphiniums are notably conspicuous; one, the Bella Donna, light azure blue. *Ranunculo-liflorum*, beautiful bronze blue and with double flowers, Herman Stenger and Nahamah, are also very fine. Spiræas are also well represented. Hardy spring bedding plants, such as *Myosotis*, *Arabises*, &c., are included in the collection. Among new bedding plants *Tropæolum Hunterii*, dwarf, neat habit, bronzy foliage, and covered with bright scarlet flowers, is regarded as a great acquisition.

On entering the houses, which are seven in number, we find healthy plants of Palms, exotic and Tree Ferns, Fuchsias, Geraniums, stove plants, &c.; while the cold frames are stocked with Camellias, Azaleas, Solanums, tree Carnations, Cyclamens, &c., medium-size plants in preparation for winter and spring blooming. Two of the houses are nearly filled with Vines in pots and now ripening off, having made an excellent growth. Planting and fruiting canes of all the leading varieties are cultivated.

The Harraby Nursery is situated at the south end of Carlisle, two miles from the Town Hall, on the direct turnpike road to London, and is twenty acres in extent. It has only been opened three years, and is principally reserved for the growth of forest trees, such as Scotch, Spruce, and Larch Firs, Sycamore, Ash, Elm, &c., for which the soil and situation is well adapted. One square of Larch contains 300,000 trees, another square of Scotch adjoining contains 100,000, while another contains 100,000 Spruce and so on, with Thorns for hedges,

Beech, Oak, Ash, Sycamore, Elm, Poplar, *Pinus austriaca*, &c.

This firm has extensive premises situated in Scotch Street near the Town Hall—office, seed shop, and warehouses.—J. A., Eskdale.

OUR Carlisle correspondent telegraphs that the preparations for the Show, which opens to-day (Thursday), are on an unusually extensive scale. The marquee for stove plants is 450 feet long by 50 feet wide, and is heated; and the fruit and vegetable tents are almost equally large. The space devoted to the Show is upwards of thirty acres in extent, and is picturequely situated between the Castle and the river Eden. No efforts are being spared by the executive to render the Show complete. The expense incurred is fully £2500, and about £1000 have been received in subscriptions. With fine weather success is certain. The exhibits are arriving, and one of the most varied and extensive Shows ever held is anticipated. It continues open during the week, and should be inspected by all who are interested in horticultural pursuits.

The first full report of the Exhibition will appear in our next issue.

ROYAL HORTICULTURAL SOCIETY.

SEPTEMBER 4TH.

FRUIT COMMITTEE.—John Lee, Esq., in the chair. Five varieties of Melons were sent from Mr. R. Gilbert of Burghley, raised from seeds that had been sent from India; but like all Indian Melons, they are worthless when grown under artificial treatment in this country. Those sent were no exception to the general rule. A green-fleshed Melon was sent by Mr. C. Rowe, The Gardens, Benham Park, near Newbury. It was cut from the third crop from the same plant, and was considered to be good, considering the circumstances under which it had been grown. The Committee desired to see it again. It has been named Benham Park Green-flesh.

A collection of five varieties of Nectarines—viz., Byron, Pine Apple, Humboldt, and a seedling yellow-fleshed, also large specimens of Spencer, but none of them were ripe. Also a fine collection of Peaches, comprising *Violette Hâtive*, Prince of Wales, Barrington, Princess of Wales, and seedlings, but neither were they in condition. These were sent from Messrs. Rivers of Sawbridgeworth. The same firm sent a collection of fine-looking Pears, but unripe. From Mr. J. Douglas, gardener to F. Whitbourn, Esq., Loxford Hall, came three sorts of Pears from pot trees, but the flavour was not first-rate, although the fruit was good-looking.

A very fine collection of thirty varieties of Tomatoes was exhibited from the garden of the Society at Chiswick; and Mr. Turner sent a dish of Schoolmaster Potato.

This was not a large meeting, but the productions were of an interesting character.

FLORAL COMMITTEE.—G. F. Wilson, Esq., in the chair. A grand and extensive collection of Dahlias was exhibited by Mr. John Keynes, Salisbury, and no less than five first-class certificates were awarded to Mr. Keynes for Countess, Henry Bond, Bessie Ford, Charles Wyatt, and Louisa Neate. The other examples in this collection were grand, and consisted of Empress, Maud, Delight, Robert Burns, George Barnes, Rifleman, Admiration, William Dawkes, Cuckoo, and Cleopatra. The whole of this collection were raised by Mr. Keynes. Other contributors of Dahlias were a collection of seedlings from Messrs. Rawlings & Brothers, Old Church, Romford; Messrs. Turner, Slough, who sent Wizard, Philip Frost, and Charles Lidgard, for which a vote of thanks was awarded; also to Mr. G. Smith, Hedge Lane, Edmonton, for a collection of twelve varieties. Mr. G. Harris, Orpington, Kent, sent Dahlias Constancy and Cavalier, which were passed. Mr. Turner also sent *Petunia Mount Beauty*, and *Carnation Lady of Avenal*, to which a vote of thanks was awarded. Votes of thanks was also awarded to Mr. Ollerhead, gardener to Sir H. W. Peek, M.P., for *Oncidium lanceanum*; and to Messrs. Veitch & Sons for an extensive collection of seedling Begonias, the greatest portion of which had been lifted from the open ground that morning, and must prove most valuable for outdoor summer display; to Mr. Parker, Tooting, for cut blooms of *Lobelia siphilitica* and *Hydrangea paniculata grandiflora*; to Mr. Kinghorn, Richmond, for *Tropæolum speciosum*, *Hydrangea paniculata grandiflora*, and *Magnolia Lœnné*.

Some very promising seedling *Lapagerias* came from Mr. J. Stokes, gardener to Mrs. Charles Crossland, Crossland Lodge, Huddersfield, for which a vote of thanks was awarded. Mr. G. F. Wilson was also awarded a vote of thanks for a fasciated flower of *Agapanthus umbellatus* and from Mr. Cannell, Swanley, Kent, came five collections of Cockscombs, twenty-four

distinct varieties of double Pelargoniums, a collection of single Pelargoniums very fine, and a box of cut blooms of his new decorative Geranium New Life, as well as several plants of the same variety, to which a first-class certificate was awarded as a decorative plant; it is certainly a very dwarf and free-flowering variety as well as a novelty. Amongst his collection of cut blooms of single varieties the Committee highly commended one named Dr. J. Denny, a decided advance on anything we at present possess. A vote of thanks was also awarded to Mr. Cannell for his collection of double varieties, which consisted of G. Magnilla, Le Constitution, Neomie, M. Sauth, M. Thibaut, M. Buchler, Le Terrible, M. C. Rontier, Jean Mace, E. Bandowin, J. Dollfus, L. Buchner, L. Boutard, M. Waddington, H. Burice, L. Lemoine, Rubis, Wonderful, J. C. Wagner, Leamington Lassie, M. R. Buist, Herzegovine, M. de Roquefeuille, and a splendid white M. Ballet. Some very fine cut blooms of Ivy-leaf Geraniums Nemis, St. George, and Gem came from Mr. George of Putney cut from the open air, and an interesting collection of a dozen boxes of Asters from the Society's gardens, Chiswick.

PROVINCIAL SHOW OF THE ROYAL HORTICULTURAL SOCIETY.

Our readers are already aware that the Council of the Royal Horticultural Society have decided to hold the Great Provincial Show at Preston in 1878. An arrangement has been made with the Preston Nursery and Pleasure Gardens Company, of which T. M. Shuttleworth, Esq., is Chairman, to co-operate in carrying out the Show, and the Company will stand in the same relation to the Society as local horticultural societies have done in former years wherever the Show has been held.

The ground selected on which to hold the Show is one of the best adapted, and certainly the most beautiful and picturesque of all the sites the Society has ever occupied. Situated within a much shorter distance of the Town Hall of Preston than the Aston Grounds are to that of Birmingham, and in close contiguity to the beautiful gardens and picturesque grounds of Flarington Hall, the site commands a magnificent panorama of Ribblesdale. In the foreground there is the river Ribble, and away in the distance Hoghton Tower, where King James I. knighted the sirloin of beef. Redscar, the residence of W. Assheton Cross, Esq., embosomed in waves of massive wood; Pendle and Pendle Hill; and Walton where Cromwell defeated the Royal army under Duke Hamilton and Sir Marmaduke Langdale. But apart from these attractions are the grounds of the Preston Nursery and Pleasure Gardens Company. These are approached by handsome entrance gates and a lodge. On either side of the broad carriage drive are specimen trees of the choicest Conifers, evergreens, and deciduous trees and shrubs, and this is terminated by a handsome conservatory of large size, in which are cultivated specimen greenhouse and conservatory plants. The great charm of these grounds is the Dingle, a deep winding ravine finely furnished with large timber trees. A stream of water runs through it, and this is utilised to form cascades at certain distances. Carriage drives and tortuous footpaths play at hide-and-seek among the dense brushwood of the undulating banks, and numerous wild flowers deck the shady glades where joyous youth and sobered age may equally find a retreat from the active and engrossing cares of everyday life.

We cannot but congratulate the Royal Horticultural Society on having secured such a position, and we have every confidence that with the co-operation of the Nursery and Pleasure Gardens Company with Mr. Shuttleworth at their head, the Provincial Show will be a great success. The Show is fixed for the second week in July, 1878, beginning on Tuesday the 9th, and closing on Saturday the 13th.

Preston is the centre of a great industrial population, and of which about seventy thousand reside in the town, and there is frequent railway communication between Blackburn, Wigan, Burnley, Lancaster, and Manchester.

BLACK PRINCE AND KEENS' SEEDLING STRAWBERRIES.

"C. P. P.," page 152, says he has discarded these two Strawberries; for what reasons we are not told. I earnestly hope none will follow his example, at least without proving them to be worthless. What I am afraid of is, that some who do not know Strawberries well may order plants according to his selection, and if they do they would leave out two of the most valuable Strawberries in cultivation. We have several of "C. P. P.'s" elect covering as much again ground as Black Prince, and although the fruit from them have been large none

of them have produced one quart against two of Black Prince throughout the season; and as for Keens' Seedling, I do not know what we should do without it to meet the demand for fruit for preserving. The family are not here in the Strawberry season, and consequently all the fruit is grown for preserving, and I find these two sorts so useful for this purpose that in a year or two there will not be a Strawberry about this place but Black Prince and Keens' Seedling.—A KITCHEN GARDENER.

POTATOES.

FROM present appearances the Potato blight is likely to be very prevalent round Edinburgh. On the 18th, 19th, and 20th of August it rained almost without intermission, and on the 22nd I observed the plague spot on my Potato plot; and like Mr. Fenn I lifted the crop instantaneously, and though not ripe they will keep for seed. On the 26th it rained a good deal, and at night on the 27th it rained freely. The river Tyne here overflowed its banks, which during twelve years I have lived here never occurred before in August. Potatoes in a number of fields in this locality are spotted and they smell very bad. The Oat fields among the cereals are as flat as if they had been rolled, and Wheat and Barley are not ripening kindly, and there will be no harvest here even under the most favourable circumstances for about ten days. Something like seven years ago Oats were cut on a farm here on July 31st. I took a note of it at the time, and named it to the farmer a week ago.

I often wonder why people are so much afraid of rain now affecting the Potato, as there were rainy seasons before the first blight in 1845. I wonder if there is any new element in nature that did not exist up till 1845, or is there any element wanting that was in force before that. These are problems I cannot solve, but I can solve this, that to my certain knowledge this valuable esculent has been treated in a spurious sort of manner. At present I have not time to say my say on such a grave matter as the loss of the Potato crop, but if all is well will make a few remarks about them next week and state facts, which are said to be stubborn things; and possibly my observations may tend to throw some light on a subject of such paramount importance to the well-being of the human family, for who can forget the famine in Ireland in 1846 and 1847, also in the highlands of Scotland and its painful results?—J. ADDISON, *Ormiston, Edinburgh.*

DRUMLANRIG,

THE SEAT OF THE DUKE OF BUCCLEUCH.

TRAVELLERS between Carlisle and Glasgow, on the Glasgow and South-Western Railway, who are inclined to admire anything remarkable as they pass along, will find their observations very richly rewarded between Closeburn and Carron Bridge stations, where the scenery—with its great expanse of mountain, plain, wood, and water—is allowed to be almost unique. Here there is no deficiency of trees or any other feature necessary to complete a truly picturesque landscape, and the country is entirely void of coal pits, public works, and every obnoxious obstruction which so often interfere with scenes of beauty elsewhere. In bold relief amidst this scenery stands Drumlanrig Castle and its princely surroundings. No words can picture the magnificence of this edifice and its connections. The accompanying view of the Castle speaks for itself, and yet with a deficiency which nothing but a personal inspection could remedy. Historical notes and traditional incidents of all that has been done in the past here are plentiful enough and might be interesting to a few; but I refrain from using your columns for any of them, because I am sure the generality of your readers would pass them over to hear of that which is more dear to their hearts and daily calling.

The gardens at Drumlanrig have always stood pre-eminent in the horticultural world, but not always on account of the excellency of the practice there. Many will remember it as a "big place" kept well dressed, and always endowed with much natural beauty. It is all these yet and more, as the excellency of the produce is far superior now to what it was ever seen or thought of years ago. With these imperfect introductory remarks I will begin my way to the famous gardens by the traveller's ordinary route from Thornhill station, and pass through the rural village of Thornhill, where the streets are lined on both sides with Lime trees, and from here to the Castle, a distance of four miles, the road seems a well-kept private drive; but it is not this, as there is no privacy about Drumlanrig. Approach it as you may no

confined wall, locked gate, or inquisitive lodge-keeper obstructs the way. Everything is free and open. To cramp such a place within a boundary wall would deprive it of much of its grandeur, and this I am sure will be felt and seen by all who visit it. But before the Castle is reached one comes upon the kitchen garden and glass houses, which the first glance shows are of no ordinary description. These lie to the right of the road; and directly opposite, on a high grassy bank overlooking the whole, stands Mr. Thomson's house. Going from here the road is crossed, and a flower garden some 4 or 5 acres in extent is entered. This is not the flower garden proper. No; only a little corner chiefly for supplying cut flowers, and is therefore mostly planted with Roses, Carnations, Phloxes, and an excellent collection of herbaceous plants; for be it remembered, that although this is the head quarters of the king of the "summer bedders," the old-fashioned herbaceous plants still find a

genial home here. There is a good extent of lawn grass in this garden, but most of the beds lie close together, and are only separated from each other by 5 or 6 feet wide gravel walks and Box edgings. The west side is bounded by an ornamental Holly hedge, the south by a bower walk covered with old Roses, Honeysuckle, and other fragrant flowers; and to the east is the kitchen garden wall. This wall is very old, but perhaps few would notice this, as the excellent fruit trees do not bear indication of ancient support.

Eight acres are enclosed within the walls. This is conveniently divided into a regular form. The main walks are 10 or 12 feet wide. One of this description goes all round the walls, with the ordinary border between. Two of these walks cross from centre to centre, dividing it into four; and then other two narrower walks run across east and west, which divide it into eight pieces of about an acre each. Box edgings

Fig. 48.—DRUMLANRIG CASTLE.

keep the soil from mixing with the gravel. Vegetables are chiefly grown for a supply during August, September, and October. It is hardly necessary to say the produce here is of the first order. Fruit trees line the sides of the walks. Owing to bad weather last autumn and unfavourable weather at blooming time many of the trees are deficient of a full crop, but others are bearing well. Large quarters are devoted to Gooseberries, Currants, Strawberries, and other small fruits, and the crops of these this year have been very good. Belts of ground, nearly as extensive as that enclosed, surround the outside of the wall on the south and east sides for growing vegetables. The south side of the kitchen garden was formerly walled like the rest, and covered with Peaches and Apricots. The first bore very imperfectly, and the latter never at all—not a very profitable covering for such a position; but a few years ago the old wall gave way, and instead of rebuilding it as before the whole was cleared away, and in its place the finest glass house of its kind in the world was erected. It is one lofty span-roofed house, 16 or 18 feet wide and 500 feet long. It is to be exclusively devoted to growing hardy fruits. It was not completed in time this spring to get the trees planted, but it has not been allowed to stand empty. It is now arranged as a flower garden. Pearson's Geraniums are grown to perfection here, many fancy-foliaged plants are mixed with the flowers, baskets filled with drooping plants are suspended from the roof, and the whole effect is far beyond any description. An

Edinburgh nurseryman told me it was worth my while coming a distance of five hundred miles to see this crystal palace, or flower garden under glass, alone, and he was right. The house is substantially built and well heated, and no doubt by-and-by it will produce fruit worthy of itself and its manager.

Leaving this structure we pass through the garden again and enter the front range of glass at the north of the kitchen garden. This is the same length as the new range. The first house is span-roofed, with its ends north and south, a bed in the centre, and shelves round the sides. Some fine specimens of Camellias are planted out in the centre, and the whole is filled with healthy, well-grown, greenhouse plants. We pass from this into a long lean-to house chiefly devoted to exotic plants and Orchids. Next is a range of Peach houses, three in number, and with a little division between comes a long vinery divided into two. Talk of Grape-growing! But if ever Grapes were grown to perfection it is in this place. Hamburghs, Muscats, Gros Colman, Alicante, Duke of Buccleuch, Trebbiano, Buckland Sweetwater, and all the leading varieties of Grapes known are here. Not a spot or blemish are to be found on them. The Vines were planted in 1873, and replaced those destroyed by the Phylloxera. That this pest can be completely stamped out from a place has been clearly and cleverly proved here. The next house is a long exotic plant stove. All the species worth growing which come under this treatment may be seen here in all their luxuriance, and the Nepenthes pro-

bably surpass any that ever have been grown in this country. Most of them are growing amongst green moss in small baskets made from hazel sticks. *N. distillatoria*, which is well adapted for ornamenting rafters, has produced many pitchers that held more than a pint of water. Most of the plants in this house and in many of the others are growing in pots thickly coated with glaze outside. It is thought the plants thrive better in them than the common porous burnt-clay pots, and much labour is saved in washing. Opening out of this last house there is another greenhouse similar in form and position to the first entered. All the houses in this range, with the exception of the Peach houses, are new, and better-constructed houses for convenience in every way it would be impossible to conceive.

Leaving this range we pass out of the kitchen-garden enclosure into a large gravelled yard covered with glass houses

and pits. Entering the first range we come to we find Cucumbers growing in a long pit, with a pathway up the centre and beds on each side. The fruit hanging here reminds one of those representations of new Cucumbers which we sometimes see in advertisements. In the same range, but with the door at the other end, is what formerly was a Melon pit, of the same description as the Cucumber one. This is now planted with Figs trained on trellises, and it is well known that at no place are Figs better grown than at Drumlanrig. They are grown on what may be termed the short-spur system, as the shoots are pinched close in so as to form fruiting buds, in the place of long naked wood often seen on Fig trees. On a line with these there is a large half-span house where Pines are grown. Further along than this there are two low pits for successional Pines, and behind these again on another range there is one more large Pine stove. To the generality of your readers

Fig. 44.—WHITE SAND GARDEN AT DRUMLANRIG.

it will not be new to be told that the Pines, suckers, successional, and fruiters in all these houses and one or two others which we have not reached yet, are the very perfection of Pine-growing. Next to the last-named Pine house there is a division of the same size set apart for *Passiflora* culture, a fruit seldom grown for dessert, but much appreciated here. Leaving this range and making for another we pass the young gardeners' lodge, where sixteen or eighteen young men reside. This lodge, or to use the vulgar term "bothy," has been greatly improved lately, and both for inside convenience and outside appearance is an ornament to the place. No person can be more anxious to have his young men comfortable than Mr. Thomson, and his example is worthy of imitation.

The next range (behind the Cucumber and Melon range) is divided into several lengths, which are filled with Vines and Figs. Close behind this there is another range of cool Orchid houses. Space forbids individualising, so I will only say that Orchids from the most common to the most rare are all grown here to a condition which the most celebrated place for these glorious plants never surpassed. Further back still there is another range of houses chiefly devoted to Pines, and not far from here there is about one acre covered with frames for various purposes.

One of the most complete arrangements about the place is the heating of all the houses. Four boilers heat all these

ranges. They are the largest size of Meiklejone's improved cruciform. They lie back from all the houses, and pipes are laid from them to the different ranges, some of the pipes running 200 feet before entering the house. A wooded slope rises on the west side of the garden. There is a large flue goes about half a mile up this wood, and at the end of it there is a tall chimney about 300 feet above the boilers, which draws all the smoke clear away from the place. This is an excellent arrangement, and very different to the smoke, fire, and heating about Drumlanrig when we first saw it; then there would not be much fewer than forty fires, as each house had a fire and chimney to itself. When these were all lighted in the evening the place resembled a small village, the consumption of coal enormous, and the smoke and dirt quite equal to it.

Leaving this, the Castle, which is one mile from the garden, may be reached in two ways—one the same way as we came from Thornhill, the other a private walk leading through the woods which, after passing rustic arbours, bridges over streams, and other adornments, brings us into the lower part of the flower garden. The enclosure under this name, which is surrounded by an elegant wire fence, extends over 50 acres. Every inch of it is kept in the finest order. Some of the ground is much higher than other parts; the Castle crowns all. Next to the house there is a wide flower bed, then a gravel walk over 20 feet in width. This is the arrangement on the south, east,

and west sides; on the north is the carriage entrance, directly opposite to the side most prominent in the engraving. This top walk forms what may be termed the top or first flat. From this a large glass terrace slopes down and finishes at the edge of another very wide long walk. To the east, at the foot of the bank, there is a large flat laid out and planted as an American garden. On the opposite or west side of the Castle there is another flat similar, but it is planted with Stocks, Carnations, and many sweet-scented flowers. Between both of these pieces and the broad walk before mentioned there is a chain border resembling the one at Dalkeith, which is planted with grand effect. The further side of the big walk from the Castle is supported by a wall over 12 feet high. Many kinds of both new and old-fashioned climbers cover this wall. Along the bottom of it there is another narrow walk, and green terraces slope down from this. At the bottom of one of these slopes, and directly facing the Castle, there is a large flat of flower beds surrounded with an elaborate border of Heath. This is named the White Sand Garden, and is well represented in the annexed illustration. The Heath is brought from some of the distant hills seen in the background in the Castle view. It is only allowed to grow about 2 inches high; it is clipped smooth, and the surface resembles green velvet. Between the Heath figures white sand broken fine is laid, which gives the whole a very chaste appearance. Looking down from above on this the effect is truly magnificent. This is much the prettiest, but not the largest design in the garden. To the right of the view is seen a terrace; on the top of this there is another large flat known as the Wilderness, and planted with fine specimens of Hollies, Yews, &c. Further down than the Sand Garden indistinct traces of other beds are seen, but between them and the Sand Garden there is another large terrace. The part at the bottom is very extensive, and is known as The Scrolls, owing to the beds running in the form of scrolls. To the left of the Sand Garden other beds are visible; these are of great extent; another large flat of flower beds is close to these. Dark-foliaged Yews of great age line the bottoms of some of the terraces, and monstrous Chestnut trees shade some parts of the walks. Choice trees are dotted here and there on the grass, and beds of rare Rhododendrons appear as backgrounds to the flower beds; but no one feature predominates over another. Although there are so many flower beds they do not cover anything like the extent of ground there is in grass, and the number of trees, high slopes, and other elevations conceal one mass of beds so much from the others that no sameness, nor too great a glare of colour, occur at one place. Thousands of Violas are used for flower-garden decoration here, as they are found to stand the wet much better than Geraniums.

The views obtained from the highest terrace close to the Castle are splendid. On a clear day objects can be seen quite distinctly down the valley eighteen miles away; and the river, which flows past not far from the Castle, is seen winding down through the green fields and wooded knolls nearly all this distance.

This, be it understood, is a very imperfect sketch of Drumlanrig. To notice everything in a proper way would more than fill a weekly number of the Journal. Names of plants, modes of cultivation, and many other notes of interest I have left untold; but to make up for this deficiency in as short a space as possible let me say that those who go home from Carlisle without seeing Drumlanrig will miss what many good judges consider as being the finest, most complete, and best-managed garden in Britain.—F. R. H. S.

FRUIT PROSPECTS.

I HAVE just taken stock of the wall fruit here (Thorndon Hall, Essex), and find that on about 8000 superficial feet of good wall there are about twelve dozen of Peaches and Nectarines, and about twenty dozen of Pears. Of these Napoleon on the east and Gansel's Bergamot on a south aspect have the largest crop in proportion to the area covered; the latter was protected by a 10-inch coping board, to which I attribute the result. Plums not more than four dozen, three dozen of which are the *Impératrice* on a west aspect. This useful old Plum is seldom seen now, yet it always bears more or less. I wonder it is not more grown. Such a light crop of fruit is but a poor look-out where there is a large family to supply; but all are alike in this locality, and we therefore sympathise with each other, and hope for better things next year. At any rate the trees have a good chance to reinvigorate themselves, and

taking them all together are remarkably healthy. The altitude of this place is 332 above sea level.—J. GADD.

FRENCH ROSE GARDENS.—No. 2.

BOURG-LA-REINE.

THERE is no difficulty in finding the way to these gardens. "J. Margottin Fils, Horticulteur," is conspicuous on the pretty little house amongst its Rose beds even before the train from Paris glides into the station. Starting from the Place d'Enfer, the Sceaux line runs to the little town of Bourg-la-Reine in twenty minutes. This side of Paris is comparatively bleak and uninteresting. Acacias, the tree of the place, edge the line. Huge forts frown on the left, and a tall aqueduct is passed half way that really would not be unworthy of the times of the Romans. Then rows of Briars and Manettis begin to appear. I disembark, and am directed by a board to the garden of M. Margottin père. Again I am unfortunate. He is not at home. A lady under an umbrella painting a yellow Tea Rose from Nature is the principal object in the central pathway of tall Roses fastened to long lines of wire. A young man in blue is deputed to guide me, but though willing enough, neither does he impart nor can I acquire much information. I acknowledge his services in the usual way and retire. I try M. Margottin fils. Here I am more fortunate. I ring at the tall iron gates. A pleasant-looking madame from an upper window bids me enter. She will send for her husband. At last I find myself face to face with the proprietor, a fine specimen of the shrewd and energetic Frenchman of the period. This is the original Jules Margottin, as I presently discover. I suggest that he and the Rose must be about the same age, but he states that his namesake was born in 1855. I do not push my inquiries. Now why is it that they always will speak English to you in France? Can anything be more aggravating than to have an elaborately constructed French sentence answered shortly in your own language? I suppose they like to air their English just as we do our French. I must admit, when pushed back in this way into my own language, I sometimes take the mean advantage of speaking it very fast, which sometimes occasions a relapse on the other side. On the present occasion the conversation was strictly in English.

The rain had been as trying here as elsewhere—for the Roses good, but bad for the Grapes ripening. The low hedges of Vine plants, sometimes *à cordon*, are very pretty. Here there was still a considerable show of Rose bloom, but looking as Hybrid Perpetuals must do everywhere in August. Evidently they had been very fine. Had he any new seedlings? Yes, an especial *nouveauté*, a seedling coming into commerce this autumn. Mr. George Paul had seen it and at once ordered a dozen. Colour bright rose, habit robust, almost as large as Paul Neyron, but keeps its shape, and far freer bloomer, called Boëddien, after a well-known French poet, whom not to know, I had to confess, argues myself unknown. This gave me an opportunity of interceding on behalf of shorter names. We were getting tired in England of such very distinguished titles. Two names are as much as any Rose has a right to; One is still better. I was also shown what is to be an improved Sir Joseph Paxton—a very bright crimson, a free bloomer. M. Margottin considers that we run too much now upon exhibition Roses, that for general garden purposes good old Baronne Prevost is worth more than half the novelties, and will last as a plant more than five times as long. He admitted the high excellence of the Général Jacqueminot strain, Chas. Lefebvre, Camille de Rohan, Louis Van Houtte, &c., but did not think that any of these were very lasting. In this I did not altogether agree with him. He thought Duke of Edinburgh weak in form, though he admitted the high excellence of its colour. He told me that his father had nothing new for this year, probably next year there would be two or three new seedlings. I left him amongst his men all hard at work budding.

His garden is evidently very good, finer Briar stocks could hardly be seen. I was much interested in their mode of budding. Many of the buds inserted were hardly visible. He did not seem to think they were the worse for being dormant. He objects to the use of worsted, and still more of cotton. What he employs is a kind of rush; he could not tell me its English name, only that it grows in water. It has this great advantage, that it breaks with the Briar growth and drops off of itself after the three or four weeks' binding-up, which he seemed to think was quite sufficient. This would not matter for an amateur, but when the budded stocks count by thousands it

must save very much labour. On the whole, though it must be admitted after a limited survey, I infer that our English seedlings are coming to the front and likely to keep there. Comparisons are odious; were they made, our leading growers would certainly not suffer by the side of foreign competitors. What I have seen in England generally has been on a vastly larger scale. M. Margottin informed me he had just taken the two gold medals given by the city of Paris at their this year's show for dwarf and standard pot Roses.—A. C., *Hotel de Louvre*.

STRAWBERRIES ON A LIGHT SOIL.

As my remarks in the Journal the other day were intended to give the result of my experience and to report on the Strawberries mentioned rather than to take up any side on the question of annual renewal, I did not intend to write again; but as one or two persons have expressed a wish that I should add a little to my notes, and the subject is not exhausted, I willingly do so.

In the first place I do not wish to mislead anyone as to the bed of Keens' Seedling. It has only borne such wonderful crops the last two or three years. Before that the crop was always a good one and could be depended upon let the season be what it might; in fact this Strawberry in the position I have it is "at home." Sir J. Paxton, President, La Constante, and others do equally well; they have now been grown four or five years, and look likely to last as many more, but I am not sure about the first. I do not feel bound by any particular time for the renewal of beds, and only do so when they cease to be profitable. "W. S. P." speaks of my method as being a rough-and-ready one. I really was not aware of it. I am desirous of following the best-known method, and I do not think I am far from the mark on my own ground. I thought of trying a few experiments with guano and soot this year, but the weather in June was too dry, so I deferred it to another year.

When I first began growing Strawberries I did not succeed as well as I do now, and was under the impression that they required more frequent renewal than I have since found to be the case, but the fact was I had not the most suitable sorts, and was not sufficiently careful about removing the weeds in time. There is no fruit crop which is so soon injured by the least neglect in that respect, or so well repays the necessary care and attention. The soil now is sufficiently moist, and I am having the beds trimmed up and cutting off all the leaves except five or six at the top, and it is a matter of indifference whether they are all cut off. On several occasions I have had a portion left so and could observe no difference in the following crop; they will be sure to throw-up plenty of new leaves before the winter. The plants will be manured with some well-decayed hotbed manure before Christmas, but I do not like the crowns of the plants covered. If the manuring is delayed until after Christmas sometimes a long period of dry weather sets in, and the full benefit of it is not obtained.

Mr. Luckhurst goes a little too far in his opening statement about Strawberries succeeding everywhere. Mr. Rivers, a good authority, says that Eliza does not thrive except on a chalky soil; and Mr. Darwin says, "That splendid fruit the British Queen can be cultivated in few places either in England or France, but this apparently depends more on the nature of the soil than the climate." A famous gardener (Mr. D. Beaton) says that "no mortal could grow the British Queen at Shrubland Park unless the whole nature of the soil was altered." At the same time some sorts are so hardy as to thrive almost anywhere.

Anyone desirous of making a selection for planting could not possibly find a better guide than the report of the Strawberry election for 1872—at least with regard to the older varieties. I have just procured Lucas and Unzer Fritz, the latter highly recommended by Mr. Ferdinand Gloede, and perhaps another day I may report on their behaviour. I am very much pleased with the remarks of "C. P. P.," who is evidently an experienced grower, although I do not follow the same method of cultivation.—AMATEUR, Cirencester.

THE COLORADO BEETLE.

In an article on this unluckily famous insect which appears in the September number of "Science Gossip," and which is from the pen of Mr. Rye, deservedly reputed one of our ablest entomologists, it is recommended in the event of its appear-

ing here to isolate the patches infected by trenches, and then cover the surface with sawdust soaked in benzoyl, which is to be set on fire. After this the land is to be ploughed, again saturated with the oil, and the surface again burnt." If the beetle could survive that it must have indeed a charmed life. But in the event of its having got too far ahead to admit of this effective process, Mr. Rye advises a systematic and unwearied search for the imagos in spring, before the eggs are deposited. It is encouraging to find that this authority is inclined to pronounce against the probability of the beetle's effecting a settlement in Britain.—J. R. S. C.

BATTERSEA PARK.

For varied and attractive scenes produced by its formation, for the diversified character of its ornamentation, and for its excellent keeping, Battersea Park has always been renowned. Every year since its establishment it has been beautiful, but never has it been more greatly and justly admired than during the present season. Its broad, smooth, capital walks, the pleasing seclusion of its quiet nooks and shady groves, its rock and water scenes, its Fern dells and alpine touches, its tropical aspect and the artistic decoration of the beds, combine to render this picturesque place of public resort increasingly popular.

Let us enter the Park by the western gate and note the character of the decorations. Mixed borders are not generally considered as being particularly attractive during the late summer; they are more frequently referred to under the convenient term of "interesting"—a term which may have a wonderful amount of meaning or no meaning at all, according to the fancy of the reader; but the mixed borders here are neither dull nor tame, but are lively and effective as such borders should be. Their effect is probably enhanced by their boldly curving nature and their front marginal lines of golden *Stellaria*, silvery *Gnaphalium*, and blue *Lobelia*. They are brightened also by the introduction of bold masses of the best of the bedding Geraniums. But what renders them especially attractive now are the rows of *Anemone japonica*, and especially its white variety *alba* (syn. *Honorine Jobert*), the flowers of which are shown to great advantage by the background of shrubs and bright scarlet *Dahlias*. *Heliotropes* in profusion impart perfume to these gay mixed borders. Crossing the carriage drive the entrance avenue becomes restricted. On both sides of it are rows of the finest massing *Geranium* in the Park, *Waltham Seedling*, and *Calceolarias*; and especially noticeable bright yet elegant rows of *Pentstemons*, behind which, and partly amongst the shrubs, are fine clumps of *Liliums*, apparently *L. lancifolium*, in variety, with numerous flowers on the eve of expanding.

A short walk across a "bit of real park" and we arrive at the decorations proper. A twisting walk less than 50 yards in length leads to the subtropical enclosure. But short as it is, this walk affords attractions on either hand—a bold dell-like recess formed amongst the shrubs, the turf smooth and clean, the beds of *Cannas* imposing, the overarching foliage of the Tree of Heaven refreshing, the *Geranium* beds affording brightness—Mrs. Turner, lavender pink, being especially fine—and isolated specimens of *Palms* and *Musas*, all commanding admiration.

We are now in the enclosure—an irregularly oval-shaped, undulated, "treeified" lawn on the one side, and high banks of dense foliage on the other, with a narrow strip of lawn next the circular walk. Towering *Cordylines*, rich masses of "tropicals," specimen *Palms*, informal mixed beds, very formal carpet beds, and a few real flower beds constitute the attractions here. A bed of the Coral Plant (*Erythrina*) interspersed with golden *Abutilon* and edged with variegated *Mesembryanthemum* fronts the entrance into the enclosure; it is a raised bed, as are the two mixed beds on either side of it. *Jacaranda mimosaefolia*, here most elegant, *Acacia lophantha*, and such like plants, are supporting mediums for *Thunbergia alata* in variety. Towards the margin a broad silver-leaved *Artemisia* is associated with *Abutilons* and tuberous *Begonias*, the beds being edged with *Alternantheras* and *Mesembryanthemum cordifolium variegatum*. These are charming beds, the *Begonias* in them having a rich yet graceful appearance. Two large S-shaped carpet beds attract the notice of visitors. Being partly under the shade of trees the object has been to render them bright and cheerful. The circular ends of the beds are planted with Golden Bicolor *Geraniums*, the remaining portion of the beds being planted

with twisted panels of Golden Feather, *Leucophyton*, and *Alternantheras*, and edged with *Euonymus radicans variegata*. They are effective, and suitable for the position they occupy. A contiguous bed in striking contrast is a circular one planted with specimen *Buonapartea* in a carpet of golden *Stellaria*. It is both novel and attractive. Besides the *Cannas* some other noticeable beds of stately plants are splendid *Wigandias* and *Aralias*, edged with *Petunias* and *Gazanias*; *Acacia lophantha* and variegated Maize, edged with *Geraniums* and *Salvia argentea*; *Polymnia grandis*, with a charming edging of *Convolvulus mauritanicus*; Variegated *Yuccas*, mixed with *Lantanas* and edged with *Geraniums* and large "rosettes" of *Sempervivums*; also *Ricinus* and *Lantanas*, *Polymnias* and *Heliotropes*, *Grevilleas* and *Vitis heterophylla variegata*, *India-rubber Plants*, and a ground of *Iresine Lindeni* and silvery *Artemisia*. Such are a few of the large beds, to which the same epithets apply—they are luxuriant, attractive, excellent.

Some oblong and round carpet beds in this portion of the Park are quiet in colour, clear in design, and chaste in appearance. One long bed, wider at one end than the other, contains a row of kite-shaped panels of *Alternantheras*, diminishing in size from the wide to the small end of the bed. The panels are banded with golden *Stellaria* and *Cerastium*, and the bed is also margined with the *Stellaria* and *Echeveria*. The angular space between the centre panels and the margin is planted with small *Kleinias* and *Sedum glaucum*. Another bed is of the same character, the panels, however, being filled with small plants of *Echeveria secunda glauca* instead of the *Kleinia*. Two round beds are also noticeable. One of them has a flowing scroll-like tracery of *Leucophyton* and Golden Feather, with panels of *Alternanthera versicolor grandis* and *A. amena*, a groundwork of the now familiar and popular *Mentha*, the centre of the bed and also the margin being planted with *Sedum acre elegans*—a very pleasing bed. Another distinct bed is planted with four pear-shaped panels of *Alternanthera magnifica*, banded with Golden Feather and edged the same as the bed last noted; the interspaces between the *Sedum* and the panels are filled with *Mentha*. A large bed, chiefly planted with the Golden Elder, and another with *Brugmansias*, are in bold contrast with the dainty carpet beds. The arrangements noticed, with a few *Geranium* beds, specimen plants of Pampas Grass, Pomegranates and *Yuccas*, render the decorations of this portion of the Park fully equal, if not superior, to those of any former year.

Passing to that portion of the Park where the picturesque miniature lakes and islands are the chief attractions a few points by the way demand notice. The first is "Fern Hollow." The turf in this has been newly laid, and the specimens of Tree Ferns, Cycade, *Dracenas*, including D. Shepherdii; Palms, *Pritchardia pacifica* being especially fine; a plant of *Pothos acanlis*, with splendid foliage; Stag's-horn Ferns, &c., are arranged with admirable taste. It is a charming "bit," but not more so than the long vista of Ferns, &c., on the opposite side of the walk. The turf here has also been renovated, and the whole "forest scene" greatly improved. At the end of the vista, which is about 50 yards long, is a plant of *Musa ensete*, the irregular sides of the narrow shady grove being decorated with Tree Ferns, *Encephalartos*, Palms, and *Pandanus*. Immediately beyond this point is one of the nooks or grassy recesses in the shrubs which render this Park so delightful. At the end of the nook, which is flanked with fine beds of *Cannas* edged with *Funkias*, is a magnificent plant of *Musa ensete*. There is no more effective and really artistic example of decoration in the Park than this is; there is not much of it, but what there is is excellent, perhaps because so little effort is apparent for producing an "effect."

Another group of carpet beds, two large oblongs and two rounds, arrest attention. They are real carpet beds—that is, the soil has not been raised in one part and elevated in another to produce an irregular surface. The oblongs are very bright, such as a great number of visitors admire. Each bed contains circular patches of *Leucophyton Brownii* surrounded with chains of Golden Feather, *Alternanthera amena*, and *Mentha*. The extreme edge and also the angles between the brighter colours are planted with *Sedum acre elegans*. The large round beds have a star-like pattern of variegated *Geraniums* as the central design, the angles being planted with *Alternantheras* and *Echeverias*. These beds are edged with *Mesembryanthemum cordifolium variegatum*. The decorations in this division of the Park are very effective. Proceeding onwards, "Alpine Point" is reached with its green valleys of *Pyrethrum Tchihatchewi*, a name which a corre-

spondent of the Journal once observed he could not pronounce without sneezing, and *Leptenella scariosa*, hillsides clothed with Cactuses, Aloes, and alpine plants, the higher mounds being planted with *Antennaria tomentosa* to resemble snow-capped mountains. On the opposite side is a contrasting bed of *Ricinus Gibsoni*; another fine tropical bed having an edging of *Geranium anemonifolium*, the large green palmate foliage of which is distinct and attractive. Passing by Ivy-clad banks a pause is made to admire a bright nook planted semicircularly with the Golden Catalpa and *Clematis Jackmanni*, with the yellow Canary Creeper associated with the purple of the *Clematis* on the one hand and a fine bed of *Fuchsias* on the other. Large plants of *Fuchsias* in shaded places grow and flower well, and afford an acceptable change from more gay and formal plants. The bed of them here is admired by all visitors.

There are yet the rockery to admire with its trickling cascades—a long, cool, shady walk, the banks being covered with roots and Ferns, and a bright example of flower and foliage grouping on the side near the Thames—the refreshment garden. The long semicircular border here is extremely gay with groups of *Geraniums*, *Iresines*, and divisional lines of Golden Feather, and a flowing arrangement of *Lobelias*, *Alternantheras*, and *Sedums*. The corners of the borders are treated in a particularly artistic manner, the ground being curved and raised to represent some rich cornice work. The same mode of decoration occurs in other parts of the border. The central beds on the two narrow lawns are planted chiefly with sweet flowers. The carpet beds here—three round beds with a connecting chain, represent what many consider as being the best, as it is the most soft in appearance, carpet bedding in the Park. The ground in the central circle is raised while the end beds are hollowed-out like saucers. The effect is novel, and the concentric lines of *Mesembryanthemum* and *Leucophyton* have a chaste and admirable effect. Intricate patterns are not the most pleasing, and mixing too many varieties in the same bed is not the most effective mode of decoration, as the excellent association of these two plants only in these circular beds clearly proves.

Such is Battersea Park in 1877. Once more the public are more than satisfied, and Mr. Rogers's reputation is well sustained. On leaving the Park a visitor observed, that "if the people have such delightful places provided for them, what must the Queen have?" I will try to tell him.—J. W.

GRAPES SHANKING.

CAN any of the numerous practical gardeners who read the *Journal of Horticulture* state the reason why Grapes grown on the open wall never shank? I simply ask this question to elicit the opinions of practical men. Why is this? I have seen Muscat of Alexandria, Grizzly Frontignan, Royal Muscadine, West's St. Peter's, Black Prince, and Black Hamburgh at various places in Sussex, Surrey, and Hampshire arrive at a sufficient state of ripeness, and have not a trace of shanking on a single bunch; yet in some instances I know the roots were not in the most favourable places to insure success.

My idea is, that the temperature of the night is so much lower than that of the day, that the plant has so far recruited its energies and taken up a stock of food for the forthcoming day. The temperature on a south wall at midday is frequently 130° to 140°, and at night down to 55°, or as low as 50° at times. This is a great range, but it is no more than an ordinary Cabbage or Lettuce endures in the open ground. The low night temperature enables the foliage to be completely charged with food, which has to be digested by the heat and light of the day.—INQUIRER.

OUR BORDER FLOWERS—LEOPARD'S-BANE.

SMALL as are the representatives of the family of Leopard's-bane they are, with the exception of two or three, anything but common. The name of *Doronicum* has been altered from the Arabic name *Doronigi*, and the plant was said to have been employed for the purpose of destroying wild animals, hence its common appellation. In our day and country we are happily free from tigers and the like marauders, yet *Leopard's-bane* deserve more attention than they are at present receiving. Common in appearance they may be, but some of them in half-wild places and shady damp banksides afford us a grand display in the spring and early summer months. When established, all they require is to be left alone; they soon increase

themselves by spreading of the root and seed. To see them in their full beauty they must be seen in quantity. They are not particular as to soil, but in such situations as I have named they are quite at home. They appear to derive much support from decayed leaves which cover them in the autumn. I like to have a patch in the border where variety is required.

There is a beautiful white variety, *Doronicum altaicum*, which is worth looking after; it requires a moderately dry situation and rich light soil. *Doronicum caucasicum* is perhaps the most commonly met with, but is not nearly so common as it deserves to be. As a spring garden plant it is very desirable. For lines, beds, and patches in my estimation it ranks very high. When established in large patches in the early spring it becomes one of the gayest of the flowers of the garden, often giving us flowers also in the autumn and winter. In the spring it sometimes requires protection. Any light material placed over it, or a few spruce branches stuck round it, will ward off the severity of the frost. Slugs are fond of hiding in the crowns of the plants, and if not destroyed they do considerable injury to the leaves and flowers. *D. austriacum*, *D. scorpioides*, *D. Columnæ*, *D. macrophyllum*, and *D. cordifolium* are all desirable border flowers, requiring little attention when once established. They are readily increased by division in the autumn and spring when growth is commencing.—*VERITAS*.

NOTES AND GLEANINGS.

We are informed that the date of the Royal Horticultural Society's PROVINCIAL SHOW AT PRESTON in 1878 will be from Tuesday, July 9th, until Saturday, July 13th, both days inclusive, and that a Schedule Committee has been appointed to draw up a schedule.

Now that England has become so great in the culture of the Rose it behoves that in speaking of our favourite flower we should be correct in our language and literature on the subject. Why do we speak of Provence Roses? There are none such. The *Provins* Rose takes its name from *Provins* in the department of Seine-et-Marne, where the great Rose-culture of France is carried on, and not from Provence, one of the ancient provinces of France. Will "WYLD SAVAGE" take the hint and introduce a more correct orthography?

UNUSUALLY cold nights prevailed during the close of August and beginning of September. A Buckinghamshire correspondent informs us that the grass was crisped with frost on the morning of the 24th ult.: we have heard also that the thermometer has been down to the freezing point in the neighbourhood of London. Low night temperature and bright days are the best possible antidote of the Potato disease. If heat with moisture prevails nothing can prevent the destructive progress of the ubiquitous murrain.

THAT excellent Grapes may be grown without elaborate border preparation many examples prove. A very good one came under our notice the other day near Penge railway station. Mr. Bailey, who had been a successful gentleman's gardener for many years, commenced Grape-growing on his own account a few years ago. Although his soil was a strong clay he did not trouble to obtain turf, bones, or concrete. He simply made a narrow ridge on the surface of the garden (not excavating) of the loamy clay mixed freely with stable manure, and in this planted his Vines, adding to the ridge as they increased in size. The Vines have for some years produced wonderfully heavy crops and no shanked berries. To borders above ground and rich surface-dressings Mr. Bailey attributes his success. Cucumbers are grown in the same manner, hillocks of soil being placed on the floor inside the house, and heavy crops are produced in the clay and manure.

FEW flower garden plants which are readily increased from seed are more varied in colour, rich, and attractive than *DIANTHUSES* Heddeiwigii, *Diadematus laciniatus*, &c., in good varieties. The seed of these is generally sown in spring, but much more satisfactory plants are produced if it is sown in August or early in September, wintering the plants in cold frames. The plants thus managed are more luxuriant, flower earlier, and are altogether more satisfactory than are plants raised in spring. The great German growers, who almost supply the world with seed of these beautiful *Dianthus*es, raise nearly all their plants in the autumn.

AN amateur cultivator, who grows a considerable number of Peaches and Nectarines on glass-covered walls, states that the best Peach is *Grosse Mignonne* and the best Nectarine *Pitmaston Orange*, and if only two trees are required by

any cultivators he recommends those varieties as being good growers and bearers, the fruit being of full average size, handsome appearance, and of excellent quality.

CANNAS are now commencing flowering in the London parks, and will be very ornamental during the present month. One of the finest varieties appears to be *C. Rendatleri*, the flowers being large and of a bright orange colour. A fine bed of it may be seen in Battersea Park by the side of the walk leading from "Alpine Point" to the rockery.

MR. WILLS'S NURSERY at Anerley, under Mr. Bause's management, is always worthy of inspection. Not only are there many thousands of *Dracanas* in wonderful variety and condition, but the ease and extent to which Ferns for decorative purposes are grown is astonishing. *Adiantums* are raised from spores with about as much certainty as Mustard and Cress from seed. There are three thousand plants of *Adiantum gracillimum*; and as to such popular sorts as *A. cuneatum*, *A. seutum*, *A. trapæziforme*, more than a thousand plants a-week, often as many in one day, are required for decorative purposes. On one of the shelves are some hundreds of seedlings of *Tillandsia zebrina*, and in that position the rich marblings of the lower sides of the leaves are very conspicuous; and on another shelf are some thousands of *Anthurium Scherzerianum* in thimble and thumb pots. Another house is almost entirely filled, and attractive it is, with the fine variegated plant *Yucca filamentosa variegata*, in the increase of which Mr. Bause is extremely successful. The outside portion of the nursery is almost wholly planted with Roses for affording cut blooms, of which ten to twelve thousand per week are required during the London decorative season. The Ferns (grown in loam) and fine-foliaged plants are in superb health, which is attributed in a great measure to the "Elixir," or buffalo-horn manure, which Mr. Bause uses to almost everything with the best results. The most valuable roof plants are *Stephanotis*, *Lapageria*, and *Jasminum grandiflorum*.

EVERY spring well-grown plants in 5-inch pots of the charming Everlasting *RHODANTHE MANGLESII* are amongst the most popular plants in Covent Garden Market. In order to produce such plants seed should be sown at the present time in a compost of peat and loam. When large enough the seedlings should be pricked an inch apart in small pots for passing the winter. When established a light shelf in the greenhouse is a suitable place for them. They require to be carefully watered at all times, never wetting the foliage. Shift them into their flowering pots in the spring; and if they are well managed, plants will be produced which few can fail to admire.

HEAT, which is a prolific source of RED SPIDER, is also, says an "OLD MELON-GROWER," an antidote of that pest. Melons, and indeed many plants, he remarks, will endure heat that is fatal to red spider if much moisture at the same time accompanies the heat. However contrary to established notions the matter may seem, our correspondent states that Melons, and plants generally which are grown in a very high temperature with much moisture, are rarely infested with either red spider or thrips. He asks those whose Melons are cut and the foliage infested to close the house or frame with much moisture, and allow the temperature to rise to and remain at 120° for an hour or two, when the plants will be found to have sustained little if any injury, while most of the red spider will be killed.

CLEODENDRON FALLAX is well known as one of the most brilliant and stately of decorative plants, but it is not so generally known that the best mode of raising a stock of it is by sowing seed and treating it as an annual. A fine example of this mode of treatment may be seen at the Crystal Palace, where a number of dwarf sturdy plants not much exceeding 6 inches high are just showing their flower spikes. They were raised from seed sown in the spring of this year. It would be equally satisfactory, probably, to treat the plant as a biennial, sowing the seed at the present time.

THE merit of being the first introducer of *FERNIS* belongs, says Mr. John Smith in his volume on "*Ferns, British and Foreign*," to Mr. John Tradescant the younger, who in early life made a voyage to Virginia; and it is recorded in Parkinson's "*Theatrum Botanicum*," published in 1640, that upon his return from that country in 1628 he brought with him amongst other rare plants the *Cystopteris bulbifera* and *Adiantum pedatum*. These, therefore, remarks Mr. Smith, must be regarded as the nucleus of our present large collections.

"RHODODENDRONS," writes one who has had much experience on the subject, "are generally considered to be the

only shrubs that hares and rabbits will not eat. I find they do nibble the leaves sometimes, especially of newly-planted shrubs, but not to a damaging extent. *Andromeda floribunda* they do not taste, and *Kalmia latifolia* is free from their depredations—in fact, most peat earth or American plants are not liked by them, none of the Heath blooms or *Erica* family being at all relished by those animals.”

— A SPLENDID collection of *CHRYSANTHEMUMS* is being grown in pots in Victoria Park. There are thousands of plants in the finest possible condition, and which will produce a rich display during the autumn months.

— THAT many of our common wild plants become highly attractive under good cultivation many examples have proved, and not many of them more conclusively than the common Harebell, *CAMPANULA ROTUNDIFOLIA*. This plant, which only grows a few inches high in dry places, becomes when grown in pots both stately and elegant, the plants becoming bushes 2 feet high and through, laden with thousands of bells and continuing attractive for many weeks.

— MR. HARDING desires that *SEDUM FABARIA* (SPECTABILE) be added to the list of herbaceous decorative plants that he recommended last week. He describes this *Sedum* as one of the best of hardy border plants, and which will well repay for generous cultivation. We concur; it is valuable alike for pots or borders when it is really cultivated, and not left to exist in a semi-starved state in which it is too often seen.

— A VERY large and successful grower of STRAWBERRIES, one who has tested all the varieties in cultivation, states that two varieties recently recommended by Mr. Luckhurst are very capricious, only doing well in certain seasons and places—namely, *Exquisite* and *Traveller*, and that these cannot be classed as useful and reliable varieties.

DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

HARDY FRUIT GARDEN.

WE recently alluded to the gathering and storing of Apples and Pears, but we have not been able to do much in the way of gathering any fruit since that time. We have a fair crop of Apples, but owing to the dry weather the maggot has spoiled nearly half of them. Further, during the last ten days rain and high winds have shaken many down from the trees. Only the earliest sorts are ready to be gathered, and we can only hope that a spell of better weather will allow the late fruit to remain on the trees until it is ripe. We shall only incur loss by gathering it before the pips are brown. It has been necessary to purchase a few trees this year, and we have already selected them to be sent home as soon as the leaves fall. Those who intend to purchase trees should see to it at once, and it is very advisable to visit the nursery and select them. The reason for this is obvious. If an order is sent the nurseryman will select the best trees he has, no doubt; but of some sorts there may be only inferior trees in stock, and when this is the case it is better to see them, and you can use your own discretion whether it is better to take an inferior tree or select another variety, of which there may be good plants in stock, in preference. The ground ought to be prepared at once for the reception of the trees. If the intention is to plant a border, or quarter, the ground should be trenched at least two spits deep, working in at the same time some decayed manure if the ground is not already sufficiently rich. It is much better to work the ground now than when it is saturated with water; also when planting the trees it is a great advantage to them if some turfy loam can be placed round the roots. It is not always possible to obtain good decayed turfy loam, but where it can be had in quantity there is nothing equal to it for placing round and amongst the roots, and we would use a barrowload for each tree. Some persons dig out the holes and place in the loam before the trees are ready; but we prefer to keep the loam in a dry place, so that if the trees come home, as is not unlikely, when the ground is saturated, they may be planted at once. It is a waste of time, and the trees are not benefited if they are laid-in until a more convenient season.

The growths of Raspberries have been thinned-out, allowing only those to remain that will be required to fruit next season; for this purpose the strongest are selected, and they are fastened loosely to the sticks to prevent their snapping at the base. The rains have just come at the right time for the Strawberry plants recently put out, and they grow apace, being free from red spider. As soon as the ground is a little dry we shall work the Dutch hoe amongst the plants to destroy weeds and prevent their growth.

PINES.

With the cooler atmosphere accompanying the rains it has been necessary to apply artificial heat. In the house where

plants have nearly reached maturity a drier atmosphere is required with as much air as possible, and the water must not be too freely applied to the roots. The plants should be allowed to become dry at the roots before applying any, and then sufficient should be given to saturate the soil to the bottom. Succession plants must not be neglected; very often it is difficult to find room for them at the time of potting the suckers, and they are crowded together into some out-of-the-way corners. Of course where this is really unavoidable the best must be made of the circumstances; but unless the suckers are well treated from the time they are potted little good can be expected from them. We always plunge the suckers in a bottom heat of at least 90°; they are not far from the glass, and are never overcrowded. Pines are seldom attacked by scale or any other insect pests if they are kept in a healthy growing condition throughout the period of their existence. The plants on which are ripening fruit should be fully exposed to light, and the temperature at night should not fall below 65°. No water should be kept in the evaporating troughs in the house, and ventilate as much as possible.

PEACH HOUSE AND ORCHARD HOUSE.

In previous numbers full directions have been given as to the treatment Peach and Nectarine trees should receive after the fruit has been gathered. Where the fruit has not yet been gathered it is desirable to be very careful with it. Our own belief is that it is not desirable to allow it to remain on until it is almost ready to drop, but to gather it carefully when it can be gathered from the trees without putting so much pressure upon it as will injure the fruit. Flat-bottomed baskets should be used in which to carry away the fruit, and it ought not to be removed from those baskets until it is wanted for use. In the bottom of the baskets place first a sheet of cotton wadding and over that a double sheet of tissue paper. In cool weather fruit carefully gathered in this way will keep for a week or ten days, at least some of the varieties will—viz., those with firm flesh; the yellow-fleshed sort *Exquisite* keeps in good condition after being gathered as long as most of the sorts. We are now gathering the midsummer sorts in the orchard house. Peaches are very scarce; owing to the want of artificial heat in the orchard house when the trees were in bloom they did not set well. Nectarines are rather better, and of the yellow-fleshed sorts, especially *Pine Apple*, there is an abundant crop. We have reported all the trees that it is intended to pot this year. This work is best done as soon as the fruit is gathered and when the trees are in full leaf. When this is the case they soon form fresh roots and become well established before the leaves drop. We have frequently taken the trees out of their pots and cut a slice an inch all round from the compact ball of roots, and then returned the tree into a pot the same size in which it had been before. It is necessary to keep the leaves damp with the syringe for a day or two until fresh rootlets are formed.

GREENHOUSE AND CONSERVATORY.

We have potted all the hardwooded plants that require it, and, if the weather continues favourable, they will yet make sufficient roots to become established before the winter. A very large proportion of Cape and New Holland plants require peat or peat and a little loam added to it, and except for such as *Aphelexis* we do not use leaf soil or manure. If the loam and peat is the fibrous top spit of an old pasture it will be quite rich enough without any addition, and it must be understood that only the best fibrous peat from an upland is adapted to grow such plants. Spongy peat, or what is termed bog earth, will not produce satisfactory results. The different species and varieties of *Statice* should not be omitted from any collection of greenhouse plants. *S. profusa* is the best of them, and where only one can be grown this must be it. *Kalosanthes*, too, with the rich crimson and rose-coloured trusses of flowers have a charming effect in collections, and we find that both these and *Statice* do best when potted in rich turfy loam, using a liberal proportion of sand and plenty of clean potsherds for drainage. This must be kept perfect too by placing some turfy loam over it, a precaution that must on no account be neglected, as any sourness in the soil through the water not escaping freely is productive of disastrous results.

Stage *Pelargoniums* have been repotted. This ought always to be done when the growths are fairly started, as if it is left too long the shoots flag and the plant is checked a little in its growth. The potting material is turfy loam five parts, one part decayed manure, one leaf soil, and sufficient silver sand to keep the compost open. The old roots are considerably reduced, and the plants are returned to clean pots not larger than they have been in before, and the balls may even be so much reduced that the plants will go into pots a size smaller. Indeed the large exhibition plants one sees at the metropolitan exhibitions are always treated in that manner. They are exhibited in pots 8½ inches diameter, and it is necessary to reduce the ball of roots sufficiently to admit of their being potted into a 7-inch pot.

The *Cyclamens* are now starting into growth, as also are the different varieties of *Primula amena*. Probably before this appears in print they will be shaken-out of the pots, the balls

will be reduced, and the plants repotted into clean pots. It is a good plan to sow a few seeds of *Cyclamen* annually, and to throw away the large plants which have deteriorated. Many of the plants continue to increase in size, and annually throw up large numbers of fine flowers, others as the corms increase in size fall off in the production of both leaves and flowers. The *Cyclamen* is one of the easiest managed of greenhouse plants, and few others give such good results for the amount of care bestowed upon them. The *Cyclamen* may be sown at any time, but we have had the best plants by sowing about the last week in January or the first in February. As soon as the seedlings can be potted-off we pot one in the centre of a thumb-pot in light soil. When the plants have made some progress they are shifted into small 60's, and onwards into their flowering pots, never permitting them to become pot-bound before repotting them. Place them on shelves near the glass in a temperature of not less than 55° at night, and by the following Christmas each plant will have an average of twenty-four fine flowers on it. After the plants are established they require the shelter of cold frames only in the summer, and a greenhouse temperature in the winter.

Cinerarias have also been potted into their blooming pots. It is necessary to pot them at this time for early blooming, and we find that the flowers are the most valuable when we can have them from Christmas onwards. We are careful not to allow a single trace of green fly or thrips to remain upon them. They require to be potted in the same compost as *Pelargoniums*.

We are now "setting" the blooms on *Chrysanthemums*. Those who are not acquainted with this should look at the strong leading growths at the point. They will find a flower bud with three or four growths starting from each side. If these growths are stopped the buds will swell; if they are allowed to grow the bud will probably perish.—J. DOUGLAS.

TRADE CATALOGUES RECEIVED.

James Carter & Co., High Holborn, London, W.C.—*Catalogue of Fresh Imported Dutch Flower Roots, &c.*

B. S. Williams, Victoria and Paradise Nurseries, Upper Holloway London, N.—Part 1, *General Bulb Catalogue*; Part 2, *Fluit Trees, New Plants, and Roses.*

James W. Mackey, 40, Westmoreland Street, Dublin.—*Catalogue of Dutch Flower Roots, &c.*

Ed. Webb & Sons, Wordsley Nurseries, Stourbridge.—*Autumn Catalogue of Dutch Bulbs and Garden Requisites.*

Louis Van Houtte, The Royal Nursery, Ghent, Belgium.—*Catalogue of Camellias, Azaleas, Rhododendrons, Lilies, &c.*

Dickson & Robinson, 12, Old Millgate, Manchester.—*Catalogue of Dutch Flowering Bulbs, &c.*

John Laing & Co., Stanstead Park and Rutland Park Nurseries, Forest Hill, London, S.E.—*Catalogue of Bulbous-rooted Plants, Roses, Spring-flowering Plants, Vines, &c.*

TO CORRESPONDENTS.

* * All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

HISTORY OF THE ROSE (T. H. G.).—It was not a natural Rose, but an artificial Rose made of gold, that Julius II. sent to Henry VIII.

BLACK ON LEAVES (S. H.).—It is a fungus, the mixture will remove it as well as the scale.

VARIETIES (X. Y. Z.).—If the Committee really mean varieties, then three distinct varieties of *Croton* would be admissible, but you had better ask the Secretary. Species might be intended.

PEAR LEAVES BLOTCHED (J. B.).—The brown blotches are caused by the grubs of the Pear-tree Blister Moth. A description and drawing of the insect is in No. 476 of our Journal.

EUCALYPTUS GLOBULUS (J. Clode).—It will endure the winter planted as you state.

ORANGE FUNGUS ON ROSES (W. A.).—No one could tell you whence the spores which cause it come from. Your only remedy is to dust the leaves and the surface of the soil with flowers of sulphur.

PEACH TREE UNHEALTHY (D. H.).—The shoot sent is much infested with mildew. All growths similarly leafless and decayed should be cut-out at once, and the trees should be syringed with a solution of Gishurst compound or soft soap made by dissolving 2 or 3 ozs. of either in a gallon of water. After syringing them dust the trees with sulphur. The trees may be in bad health in consequence of old age, unsuitable soil, or inclement weather, or all combined. You afford us no data to guide us to a satisfactory conclusion as to the real cause of their ill condition.

CLIMBING DEVONIENSIS (E. F. W.).—I do not consider this a good autumnal Rose, but certainly it is a Perpetual. Anyone who tries such a Rose as *Solfaterre* or *Rève d'Or* by the side of Climbing *Devoniensis* will be struck by the difference in blooming in the autumn. These Roses are growing against my church porch, and while *Solfaterre* is now blooming freely *Devoniensis* has only two poor blooms. Climbing *Devoniensis* requires the same treatment as to pruning as any other Roses. Only the dead wood should be cut out.—WYLD SAVAGE.

ASPHALT WALKS AND ROADS (A Correspondent).—Take two parts of very dry lime rubbish, and one part coal ashes also very dry, and both sifted fine. In a dry place on a dry day mix them, and leave a hole in the middle of the heap as bricklayers do when making mortar. In this pour boiling hot coal tar, mix, and when as stiff as mortar put it down 3 inches thick to form the walk. The ground should be dry, and be beaten smooth. Sprinkle over it coarse sand. When cold pass a light roller over it, and in a few days the walk will be solid and waterproof. A neater appearance is given by sprinkling with spar, yellow or other gravel, which must, of course, be fine, and put on immediately after laying down the asphalt in place of the sand. It will bear horses without breaking-up.

AMARYLLIS LONGIFOLIA AND PANCATIUM MARITIMUM NOT FLOWERING (A. H. S.).—Give them a cool stove temperature and a good supply of water when growing; as they approach the resting period, which is ascertained by the leaves changing yellow, gradually withhold water and keep the plants dry for three months.

WORMS IN SOIL (J. H.).—We cannot give you better advice than to apply clear lime water to the plants. We also advise you to procure different soil if possible. Soot water does good to many softwooded plants and is repugnant to worms.

TREATMENT OF YOUNG VINES (L. H.).—Cut the canes back to within 5 feet of the base of the rafters. It will be better not to plant any fresh Vines this year, but if you have taken up only one rod from each, train up a second rod from each of the Vines. That will give you six rods in the house at 1 foot 3 inches from each end, and 2 feet 6 inches apart. If the Vines grow very strongly five rods will be sufficient at 3 feet apart and 1 foot 6 inches from each end.

EVERGREEN CLIMBER FOR UNHEATED CONSERVATORY (R. M.).—*Berberidopsis corallina* is the best plant for your purpose. It has handsome dark-green foliage and crimson coral-like flowers. Give the roots a plentiful supply of rich soil, water freely, especially during summer; keep the foliage clean by sponging and syringing, and it will make a strong growth, covering a large area of wall quickly, and be gay with flowers in August and September.

GRAPE VINES ON A WALL (J. B. A.).—Let the wires be 1 inch from the wall, the horizontal branches 18 inches apart, the spurs 12 inches apart, and the Vines 8 feet apart.

TENDER BEGONIAS (G. L. Whitby).—Cut off the old growth down to the fresh shoots, to which afford every encouragement, and thus secure a fine late bloom. Liberal doses of liquid manure will materially assist this second growth and prevent exhaustion of the tubers.

BARK-BOUND FRUIT TREES (A. B. G.).—Scoring the bark of fruit trees with a knife is an antiquated way of trying to afford relief to trees that have become bark-bound through imperfect root-action arising from something wrong in the soil, such as a want of nutriment, or that sodden sour condition which is caused by an accumulation of stagnant water. Instead of hacking about the bark we now turn immediately to the roots and the soil in which they are growing, doing all we can to drain, enrich, and sweeten it, knowing that if we can get plenty of healthy roots established in a sound wholesome soil the health of stem and branches will follow in a season or two.

READ'S CHALLENGE BOILER (G. D. Mundy).—From what we know of this boiler we believe it will suit you very well for heating your small greenhouse 12 by 15 feet.

WATER LILIES PLANTING (Colonel M.).—The water is too deep. The Lilies should be planted in about 3 feet depth of water. If there is mud or the pond has a soft bottom we should merely secure a stone to each root with wire and drop in the water at the places desired. If, however, the bottom of the water be gravel or other firm substance, we should plant the plants in strong loamy soil, just covering the root portion of the plants with soil and make the plants secure in position with wire, pushing them into the requisite depth of water. Shallow wicker baskets, as fishing hamper, answer well for placing the plants in. The best time to plant is in spring (March and April) up to May and June; the earlier the better, so that the plants may make some growth—become established before winter. Plants may be procured of most nurserymen, especially those growing herbaceous plants. We cannot recommend anyone in particular. Other desirable aquatics are—*Villarsia nymphaeoides*, *Aponogeton distachyon*, *Iris pseud-acoris*, *Stratiotes aloides*, *Potamogeton oblongus*, *Richardia ethiopica*, *Butomus umbellatus*, *Alisma nutans*, *Hottonia palustris*, *Polygonum amphibium*, and *Ranunculus aquatilis*, all of which succeed in from 18 inches to 2 feet depth of water. They may be planted as described for the Water Lilies. *Nymphaea alba* is the white Water Lily, and *Nuphar lutea* the yellow Water Lily. Propagation is effected by division. On the margin, in water, you may have *Epilobium hirsutum*, *Lobelia Dortmanni*, *Lythrum Salicaria*, *Caltha palustris* (dore-pleno), *Cyperus longus*, *Juncus glomeratus*, and *Acorus Calamus*.

PAINTING WOODEN GARDEN FENCE (Idem).—We should paint the wood when thoroughly dry with thin creosote at a temperature of 180°, and in three weeks or a month paint with anti-corrosion paint stone or oak colour. We have a diamond paling fence done over with thin cold creosote about eleven years ago, afterwards painted oak colour, and the paint is as good apparently as when first put on. See what "OBSERVER" writes respecting this mode of painting at page 119 of the Journal for August 9th. The wood wall would be better wired, but the wires ought not to be more than half an inch from the wood.

STOPPING BUDDED ROSE GROWTHS (St. Edmund).—You did right to stop the growths to prevent the growths flowering; but wrong if you stopped closely, inasmuch as with a moist autumn the eyes at the base of the shoots may start into growth, such growths, from the wood not being ripe, often being killed if the winter prove severe. The plants may be transplanted to their permanent quarters in November, or so soon as the leaves fall, or a majority of them. Merely remove the flower bud from those advancing for bloom.

MARÉCHAL NIEL ROSE CUTTINGS (Idem).—Take up the cuttings now, potting them in pots no larger than will hold the roots easily, and place on ashes in a cold frame, shading from sun until established. The pots should be plunged in ashes to the rim or a little over before severe weather, in which a protection of mats over the lights will be found serviceable. Plant out in late March or early April. We presume you intend to plant against a wall or in a warm situation.

NAMES OF FRUITS (W. Berks).—Early Nonpareil. (A. H.).—We do not recognise the Apple. It is fearfully acid, and is no doubt good in pies. This is an illustration that an Apple which suits a boy does not always suit a

man. (P. E., Fowley).—We do not undertake to name more than six specimens, and they are as follow:—2, Hawthornden; 4, Golden Pippin or Yellow Ingestrie; 5, Scarlet Nonpareil; 10, Trumpington; 12, Sturmer Pippin; 14, Northern Greening. (W. R.).—Whorle Pippin.

NAMES OF PLANTS (F. G.).—1, Filago germanica; 2, Gnaphalium uliginosum. (Rosenkranz).—6, Rhus cotinus; 7, Veratrum viride; 5, Linaria Cymbalaria. Other specimens unsatisfactory. (L. E. L.).—1, Polygonum amphibium; 2, Mentha hirsuta; 3, Verbena officinalis. (E. H. H. S.).—1, Yes; 2 and 3, Both apparently Lastrea spinulosa. (G. E. L.).—Aster Triplicorn. (G. M. V. C.).—Salisburia adiantifolia. (W. H. S.).—1, Polystichum aculeatum; 2, Lastrea dilatata. (R. A. P.).—1, Lastrea Filix-mas; 2, Athyrium Filix-femina; 3 and 4, Lastrea dilatata.

POULTRY, BEE, AND PIGEON CHRONICLE.

THE WESTMINSTER AQUARIUM SCHEDULE.

We had hoped to comment upon this schedule with those of one or two more London shows, but Mr. Nicholls is holding back his bill of fare for the Alexandra Palace, and the Agricultural Hall's has not yet come to hand. We are anxious to notice this schedule, for we were told we were hard upon the Committee last time; but we were not alone in our opinions that things were badly managed at the last Show. Still the Cat Show arrangements were all that could be desired, which makes us certain that this time we shall not have again to complain. The officers once more appear to be the same, and we hope they will find themselves well supported; but there are so many capital schedules of prizes afloat, and hence we conclude the poultry classes are here and there in this schedule a little meagre. The ten rules and regulations are all much as usual, with the modern improvement of double baskets only on this occasion. We read "exhibitors must send birds of the same variety in the double baskets."

The Judges are announced, and comprise for poultry Messrs. Hewitt, Teebay, and Nicholls; while in Pigeons we see some new names, the Judges being Messrs. Betty, Esquilant, Graham, Hawley, Norman, Hill, and Wiltshire, with one blank place to be afterwards settled. Poultry have nineteen cups and Pigeons thirty-three, inclusive of Capt. Norman Hill's challenge cup or vase, value £15 15s.

In our schedule we read that the poultry classes are for birds of any age, but we have seen a schedule with a blue line drawn through the words "of any age," and we have reason to believe that the classes are for birds of the year only. Silver-Grey and White Dorkings compete together, as do Black and White Cochins. Houdans, Crêves, and La Flèche all have to meet in the same class, while the Spangled Hamburgs of both colours, as well as the Pencilled, do the same. Polish have four classes, two we are glad to see being for the Blacks. Brown and White Leghorns compete together in single birds, while Malays, Andalusians, and the Variety class are in pairs of cockerel and pullet. Bantams have six classes, Ducks four, and Geese and Turkeys none at all.

We come next to the Pigeon list, which is most admirable, Pouters having eleven classes, two of which are for Austrians; Carriers having fourteen, one being a champion class for cocks. English Owls have also a similar place allotted to those which have won not less than three first prizes of the value of £1 each. Turbits are well cared for, and we heard a great Turbit fancier speak in the highest terms the other day of the mode of classification. Among their seven classes one is for Shell-crowned and another for birds of the year. The opportunities which Dragon, Barb, Tumbler, and Jacobin fanciers have are manifold, and we can well imagine the display will be grand. We are glad, too, to see Fantails other than Whites have a class; while there are also places for Nuns, Trumpeters, Swallows, Archangels, Magpies (of two colours), and Runts. We must mention the poultry and Pigeon prize money is the same, which is most unusual, and should be heartily welcomed by the Pigeon fanciers. The entrance fees are 7s. 6d. per pen for poultry and 6s. for Pigeons, which we consider high, especially the former, after other shows, as Weymouth, Ipswich, Oxford, &c. The entries closed on September 3rd, and, though we have no reason or instructions to mention it, still we daresay the Hon. Secretaries will accept entries posted to-day, as this notice was unfortunately omitted last week; anyhow exhibitors can but try.—W.

GAINSBOROUGH SHOW OF POULTRY, &c.

For some years Gainsborough has been under a cloud as regards exhibitions of this nature, the last one, in 1873, proving a total failure as regards financial matters, but on Wednesday last one was held which proved a great success in every respect. For poultry and cage birds a capital marquee was provided, and Turner's pens were used. Game headed the list with a rare entry, but many of the birds were deep in moult, others being too young for successful competition, the cup being awarded to a capital Brown Red cock, which was, however, a little out of feather; second a Black Red in nice order. Hens.—First a sub-

stantial Brown Red, second a Black Red, and both in good feather; and here we recognised old acquaintances that would have been higher but for their ragged state. Cocks, any other colour.—First a Duckwing and second a Pile chicken; and in hens first was an uncommon good Willow-legged Pile and second a Duckwing, good in all points but a little dark in eye. Only one pen of Spanish, which won the section cup. The next section of any note was the Bantams, in which were some capital birds, the cup going to a Black Red cockerel in full bloom. Ducks were—first Rouens.

Rabbits had three classes, those in the Variety class being very good. First a Silver-Grey, second Angora, third a Belgian Hare, and extra third a Silver-Grey also.

Cage Birds were very good for the time of year, Parrots being an extraordinary class.

POULTRY.—GAME.—Black-breasted and other Reds.—Cock.—Cup, 1, and 2, W. Rudd. *who*, J. F. Walton. Hen.—1, F. Sales. 2, W. Rudd. *who*, J. F. Walton. Dr. Cameron (2). Any other colour.—Cock.—1, W. Rudd. 2, J. F. Walton. *who*, J. Wright. Hen.—1, W. Rudd. 2, Dr. Cameron. *who*, J. Wright. SPANISH.—Cup and 1, J. Powell. BANTAMS.—1, Miss I. A. Swanson. HAMBURGS.—Spangled.—1, Holmes & Deane. Pencilled.—1, H. Kidger. 2, G. Roberts. ANY OTHER VARIETY.—1, H. Kidger. 2, W. Wrack. ANY VARIETY EXCEPT GAME.—Cock.—1, R. Newbitt. Hen.—1, R. Newbitt. 2, M. Allitt. BANTAMS.—Game, Black-breasted.—Cock.—Cup, 1, and *who*, W. F. Entwistle. 2, E. Walton. Hen.—1, E. Walton. 2 and *who*, W. F. Entwistle. Game, any other colour.—Cock.—1, W. F. Entwistle. 2, E. Walton. *who*, W. F. Entwistle. J. H. Roberts. Hen.—1, W. F. Entwistle. 2, R. Newbitt. Any variety except GAME.—Cock.—1, Ludlow & Rackham. 2, H. Hooper. *who*, C. J. Dadds. Hen.—1, C. J. Dadds. 2, Ludlow & Rackham. DUCKS.—1, J. E. Croft. 2, A. & W. H. Silvester. *who*, W. Bygott (2). SELLING CLASS.—1, R. Newbitt. 2, F. Sales. CAGE BIRDS.—CANARIES.—Yellow.—1 and 2, Mrs. Green. Buff.—1, Mrs. T. Green. 2, W. Hill. Green or Variegated.—1 and 2, Mrs. T. Green. LIZARDS.—Gold or Silver-spangled.—1, Mrs. Green. 2, W. Hill. GOLDFINCH.—1, Mrs. Green. 2, Mrs. Burwell. LINNETS.—1, Mrs. Green. 2, V. P. Palmer. PARROT ON A PEG.—1, J. Gorman. 2, Mrs. A. Hart. 3, J. King. *who*, A. Waterhouse. J. King. ANY OTHER VARIETY.—1, J. May. 2, Mrs. T. Green. Extra Price, J. G. Stockton. *who*, Mrs. T. B. Ward, J. King.

RABBITS.—LOP-EARED.—Buck or Doe.—1, T. & E. J. Fell. 2 and *who*, J. Taylor. HIMALAYAN.—Buck or Doe.—1, G. W. Roberts. 2, A. Brown. ANY OTHER BREED.—1, W. Lunley. 2, J. H. Roberts. 3, T. & E. J. Fell. Extra 3, S. Ostler.

JUDGE.—Mr. E. Hutton.

SKIPTON-IN-CRAVEN POULTRY SHOW.

This Show was held at Skipton in the Park on Friday last. The pens for poultry are of the oldest pattern, and for years some dissatisfaction with them has been expressed by exhibitors, but there can be no doubt that they have proved very useful in this case; the tops being of wood, span-roof style, the birds suffered little or nothing from the wet, and were quite as good to judge after the drenching rain as when newly penned, but one great improvement had been made—viz., canvas had been stretched across the backs, rendering them quite comfortable.

The classes were for young birds, and the entry was the best we have seen this season. Of Game we can say little, as they were but poor except the cup pen of Piles. Buff Cochins were very good, but Partridge were better, a very well-grown pair of the latter variety carrying off the cup for the section. Brahmas of both colours were very good, but not as forward as the above. Spanish were a surprise in quality and condition, and made an easy win for the cup. Dorkings were well grown. In Polish were some good birds, Black, White-crested, and Golden winning respectively. French were a fair lot, the first-prize Crêves standing quite out. Hamburgs were, as usual, a capital section, and in some cases the competition was unusually keen. In Gold-spangles the first-prize pullet was just perfect, the cockerel very good but rather raw, yet the other winners very good also. In Silver-spangles the competition was close, every pen containing one or more good birds, but to our eye many of the pullets had undergone severe manipulations on the rump or tail coverts, and hence the awards were made to the most honestly shown specimens. Gold-pencilled were not as good as a class, but the two first cockerels were most perfect in colour and lacing on tail, but very young, the cream of this section being the first in Silver-pencils, which as a pen surpass any we have seen for some time, and were awarded the cup. Blacks very good and neat in head properties and high in colour. Game Bantams a rare lot and every pen mentioned, and the winners Black Reds. The Selling classes were large, and there were many cheap lots.

Geese, Turkeys, and Ducks were all good classes, the Aylesburies being particularly fine in quality.

Pigeons had but a poor list and were mostly in pairs, and in consequence the entry was poor, but there were some very good birds shown. A good list for Pigeons would pay well here.

POULTRY (YOUNG).—GAME.—Black or Brown Red.—1, J. F. Walton. 2, H. Belden. 3, J. Fortune. Any other variety.—Cup, 1, and 3, J. Walton. 2, G. Ambler. COCHINS.—Buff.—1 and 2, C. Sidgwick. 3, J. H. Jones. Any colour.—Cup and 1, C. Sidgwick. 2, J. Wood. 3, J. H. Jones. BRAHMAS.—Dark.—1, Horace Lingwood. 2, T. Pye. 3, H. Wilkinson. Light.—1, Horace Lingwood. 2, J. H. Jones. 3, H. Belden. Holt. 2, E. Mawson.

JUDGES.—*Poultry*: Mr. E. Hutton, Pudsey. *Pigeons*: Mr. W. Cannon, Bradford.

TODMORDEN POULTRY SHOW.

THE eighth annual Show was held at Todmorden on Saturday last, in Sandholm Fields, a site we cannot look upon as very suitable for the purpose, but no doubt the best to be had. This Society has often suffered from adverse weather, and so severe have been its trials that it was given out as the last to be held had the weather on this occasion proved unfavourable, but a splendid day came to the rescue, and the threatened collapse of the Society was averted. The pens (Turner's) were arranged in the open field, and the attention to the birds by the Stewards very good.

Game were not a good lot—in fact, we do not find good classes of this variety this year, but a nice pair of Piles carried off the cup. *Brahmas* were better, especially the Dark ones. The first containing a nice cockerel though rather raw yet, and the pullet very pretty in her marking. Light *Brahmas* were the only breed that was treated to a class for old birds. *Cochins* were good in both classes, the first-price Partridge especially fine in growth and general quality. *Dorkings* were good and well forward, but the *Spanish* were the cream of the poultry classes, and carried off the cup for poultry except *Game*. *Hamburgs* a nice show, the Silver variety standing out from the others; and in *Bantams* the Black Reds were a head of the rest. *French* had a class, but only three pens were shown. Polish, first White-crested Blacks, second Golden. *Leghorns* and *Sultans* each were provided for with very good results. There was a section for local poultry, and the entries came up pretty well, the medal for the best going to an adult pen of Dark *Brahmas*.

Of *Pigeons* were a good entry, and there were some good birds shown in most of the classes. The cup for the best pen in the Show was awarded to a Black Carrier cock.

Rabbits had a few classes. In Lops, first was a Blue-and-white, and second a Black. *Angoras* were an extraordinary class for quality, the first combining all the grand properties of the breed—viz., quality and amplexness of fur with size and neatness of ear. The second won by very little, being much smaller but quality excessively fine, as also were many others. *Himalayans* also good, the first-price winner a surprise, for ten days before it was quite grey on feet, but here it was grand in colour; the second also very good, and three others also very highly commended. Of *Silver-Greys* there were but four, but these were so even as to puzzle one, all being nearly perfect. In the Variety class first was a Black Dutch, and second a Silver Cream; and in the Selling class a Dutch was first and an *Angora* second.

There was one class for *Cats*, the first being one of the best red Tabby kittens we have seen for some time, and second a White Persian; a very good red Tabby *Angora* was very highly commended.

POULTRY.—*GAME*.—*Black Red*.—*Chickens*.—1, J. F. Walton. 2, T. Dyson. *Brown Red*.—*Chickens*.—1, J. Walton. 2, G. Bell. *Any other variety*.—*Chickens*.—1, J. F. Walton. 2, G. Ambley. *who*, J. Greenhalgh. *BRABRA*.—*ROPER*.—*Dark*.—*Chickens*.—1, R. P. Percival. 2, Fletcher & Hutchinson. *Light*.—1, R. P. Percival. 2, A. Begg. *Chickens*.—1, R. P. Percival. 2, Fletcher & Hutchinson. *COCHIN-CHINA*.—*Partridge or Buff*.—*Chickens*.—1 and 2, C. Sedgwick. *Any other colour*.—*Chickens*.—1, C. Sedgwick. 2, H. Beldon. *DORKINGS*.—*Chickens*.—1 and 2, T. Briden. *who*, J. Walker. *SPANISH*.—*Chickens*.—Cup, 1, and 2, J. Powell. *HAMBURG*.—*Gold-pencilled*.—*Chickens*.—1, H. Fickles. 2, J. WARMINSTER POULTRY SHOW.

THIS excellent little meeting was held on the 30th ult., and the greatest credit is due to Mr. Hinton for having worked-up the Show to so satisfactory a stage. Birds from long distances competed and the quality was extremely good. Mr. Sainsbury awarded the prizes, and the pens were Billet's of Southampton.

In *Dorkings* the first-price pen were good square birds but out of feather. We were, however, pleased to see Miss Milward exhibiting here. The *Dorking* chickens were not of much account save the first-price pen. In the next class, which was for *Asiaties* of any age, a good pen of Buifs came in first; but we fancy Mr. C. Bloodworth was lucky to obtain the extra prize for the best pen in the Show with them, as the cock was much ticked on the wings, and our own choice for this honour would probably have been the first-price adult *Spanish*, which were most excellent in combs and faces, and came from Mr. Jones of Bristol. In the next class, for *Asiatic* chickens, the first prize went to good *Whites* (Woodgate), while third went to nice *Light Brahmas* (Scannell), which changed hands during the Show. *Game* and *Malays* were good, the latter breed especially well represented by Mr. Hinton, one of whose pullets we thought very grand in shape and bone. *Spanish* won first in the mixed collection of *Spanish, Leghorns*, and *Andalusians*, as they did, too, in chickens, and both were good pens. In *Polands* Mr. Burrell had a fine pair of *Gold*s, but the cock's tail was much broken. The class, however, was an interesting one. In *Bantams* good *Black-booted* won first, a really excellent pair belonging to Mrs. Holmes; and *Silver-laced* were second, but too large and coarse. Next followed two very nice *Variety* classes, the one for adults and the other for chickens. Here Mr. Woodgate won both the first prizes. He was, however, in chickens closely pressed by Mrs. Holmes. Both classes afforded a very good display of this breed. The cottagers' class was less good than we hoped to find, only a moderate pair of *Andalusians* were first.

The Carriers and Pouters of Mr. Holmes and the Baldheads and Fans of Mr. Hinton, jun., were most praiseworthy; and the collection of *Cage Birds* attracted much admiration. We were quite pleased to see them so well represented, and one talking Parrot was most amusing, though he delighted in damaging his prize card.

Now that Mr. Hinton has placed his Show on so good a footing we hope it will continue to progress, and that the classes another year will be even further increased.

COTTINGHAM POULTRY SHOW.

THE annual Show took place at Cottingham on Wednesday, the 29th, in Mrs. Gee's grand Park, which is unsurpassed with its splendid foliage for such a purpose. A capital marquee was provided for the poultry in consequence of its two days' duration, which latter arrangement we consider a mistake for the amount offered in prizes, and yet the entries were good. In poultry there were some good birds, particularly among the *Hamburgs*, *Bantams*, and *Ornamental Ducks*.

Pigeons were good in all classes; the Pouters, as usual, a capital lot; the Carriers in both classes also well represented, and some capital birds were shown in the class for young ones—first a *Black Pouter*, second *White*, and third a *Carrier*.

Rabbits were not a large show, but there were some good ones, especially among the *Silver-Greys* and the *Variety* class.

JUDGES.—Mr. E. Hutton, Pudsey.

APIARIAN EXPERIENCE IN 1877.—No. 3.

It remains for me now briefly to describe what I found on my return home, after five weeks' absence, on the 13th of August. First I observed an utter absence of drones, of which there were considerable numbers in some of my hives on the 9th of

July. I think I never remember so absolute a destruction at this time of year. Of course the population of my various hives was much diminished, and it became apparent that very little comb—in some hives none whatever—had been constructed in hive or super in the interval of my absence. Not only so, the honey visible in the cells was greatly short in every case of what it had been, while some populous hives appeared to have no honey at all. One of the supers contained 7 lbs. of honey-comb, which is the total amount of my harvest this year. Another was completely rified of the honey it had contained even in sealed cells. The same was the case with the sectional supers, so that I have nothing to report as to my trial of them, save only that in one case the bees had carefully followed the artificially made guide combs attached to the sections, and in the other had as carefully ignored them, building irregularly curved combs and preferring to build combs at lesser distances than the furnished guides. I cannot doubt, however, but that the bees would have accurately followed the guide comb in every case if only honey had abounded as in ordinary seasons. This year the white clover harvest, as to honey, has proved a total failure in these parts. No visible addition has been made to their stores by the bees in all my hives since about the 12th or 15th of June, when scarcely any of it was in bloom this very late season.

Since my return home I have been diligently feeding more or less copiously eight out of eleven hives, only two of which appear to have sufficient stores to last till spring. The two weakest have since been joined into one, after removing (by driving) the queen of that which had the least distinctly marked Italians. Sixty pounds of food have thus far been consumed, and they are still quietly storing away from 1 to 2 lbs. each hive. Of course while this is going on the queens in every case are laying eggs, and a good deal of pollen is being carried in.

Being one of those who greatly admire the Italian sort I have introduced two queens in place of two degenerate ones. The reception in both cases was very welcome, and both hives took the queens through a hole in the crown-board within eight hours of the removal of their own queens. One of them is breeding largely, the other not so evidently yet.

Altogether I think my bees are strong in numbers, vigorous in health, and in a week or two will be so well supplied with stores that I am trustful for the future; and as all have young queens under two years old at most, and all are well housed in good sized and clean hives, I am content.

I may add that two or three sorts of contrivances for feeding are in use, but I find none simpler than a wide-mouthed bottle with one or two caps of lino tied over them and inverted upon perforated zinc over a hole at the top of the hive. I find that most of the hives will take down from 2 to 3 lbs. a-day. In the open air I am careful to cover the bottles, so that robbers are nowhere.—B. & W.

BEE-KEEPING IN 1877.

FROM all quarters comes a doleful cry from bee-keepers of a poor honey harvest, not only in England but on the continents of Europe and America; indeed in California, the paradise of the honey bee, from where last year the principal bee-keeper, Mr. Harbison, sent to market 100 tons of honey, has not now honey enough to keep the bees over the winter. Many persons in California follow bee-keeping as a trade, and, being generally men of no capital, the total loss of harvest threatens them with ruin from their inability to provide food for their workers. A writer in the American "Bee Journal" states that he has not had a square foot of new comb built in his apiary this year, when a year ago an ordinary swarm would fill its hive in ten days; and at the present time more than half the bees in his county are in a starving condition, without an ounce of honey or cell of brood. We may console ourselves in England that things are not so bad as that, but yet in many instances food must now be given for storage if we would save our bees. In my own apiary not a single one of ten swarms has given me any surplus, and more than half have been storing an artificial supply for these three weeks past. The remainder have also been slowly fed to stimulate breeding, the result being that I have an abundance of young bees to winter with—an item of the utmost importance for spring success, as bees born before September, queens excepted, will never live till April.

From the very general tales of failure it is pleasant to turn to a case of success, more especially as the result may be fairly ascribed to the intelligent appreciation and earnest desire for advancement of a working man whom I may claim in some measure as a pupil of my own. This man, whom a contemporary styles "the Buckinghamshire Champion," came to me in 1874 to enter as an exhibitor at the Crystal Palace Show. He told me he had about forty stocks, from which he cleared between £5 and £10 a-year, keeping his bees in the old-fashioned style of his neighbours. He was fairly successful with his exhibits, and has been more to the fore every year since, thanks to the numberless bees he has rescued from the brimstone pit of his neighbours to strengthen his own stocks with, timely help to

his favourites when needed, and an ever-readiness to adopt anything in the way of mechanical assistance to his bees. At Weston-super-Mare Show last month his prize awards in various classes were five firsts, two seconds, one third, and silver and bronze medals of the British Bee-keepers' Association; at Sherborne five firsts, two seconds, and bronze medal; and at Dorchester two firsts, silver and bronze medals, and three extra prizes; and doubtless he will be heard of at other provincial shows yet to come off. In such a season as this it is no little to the credit of a working man that he is able to show over twenty fine supers of honey, beating both gentle and simple wherever he has competed.

The American comb foundation has this year been tried by most of our leading bee-keepers who use frame hives; and if I except Mr. Cheshire, who has a rival arrangement of his own, everyone pronounces it an unqualified success. With these wax sheets there need be no more crooked combs nor undue quantity of drone comb. These two things are under the absolute control of the bee-master, and the start the bees get at a time when most needed is wonderful. I have just sent to America for another 100 lbs. of the prepared sheets and a machine to make them with here, although I doubt if they can be produced in England so cheaply as they can be imported, which is under 2s. 6d. per lb.—little more than the price of wax. The season closes without the great metropolitan meeting of bee-keepers that has taken place each of the three previous years. Many persons regret this, and we hope the Association will be enabled next year to announce a great bee and honey show at the Crystal Palace once again.—JOHN HUNTER, *Eaton Rise, Ealing.*

REMARKS.

29th.—Fair but rather dull morning, but fine bright day afterwards throughout.
30th.—Fair and fresh, but rather windy morning; rain before noon, but fine afternoon and evening.
31st.—Fine fresh morning, some showers, but on the whole a pleasant day.
1st.—Very bright fresh day throughout.
2nd.—Very bright and fine, but rather cool in the morning, and so continued all day, except a few drops of rain about 4 p.m.
3rd.—A very showery day, the showers at times very heavy, and the air very cool all day.
4th.—Beautifully bright and fine all day, with nice fresh breeze.
Moderately fine autumnal week. The rain here has not been heavy.—G. J. SYMONS.

COVENT GARDEN MARKET.—SEPTEMBER 5.

TRADE remains as before—quiet.

From observations taken near London during forty-three years, the average day temperature of the week is 67.9°; and its night temperature 45.6°.

SUMMER-FLOWERING HARDY HEATHS.

IN August the number of hardy plants in flower is sensibly diminished; those of former months have no attraction, or interest except for seed; few new ones succeed. True this is of herbaceous and ligneous plants, wild or cultivated, indigenous or exotic. The moors, however, are then in their chief beauty from the different kinds of Heathblooms with which they are clothed—clad in the choicest garb of purple hue. Matchless, indeed, for softness of purple colouring is a wide expanse of moor in August, the multitudinous blossoms—tiny bells—chime a welcome that no one knows so well how to appreciate as the wearers of “purple.” I confess to knowing no spot so fitted for a ramble in August as an upland moor. The bright glow of the Heather, its aged growths silvered by Lichen; the monotony broken by patches of Bracken, with here and there, stunted or closely cropped by mountain sheep, grouped or isolated Gorse in glaucous freshness; Rowan tree gladdening with its clustered coral-red fruit; finding at your feet the golden green of the Bilberry and its refreshing purple berry with a bloom upon it that no black Grape may equal; bathing the feet in sphagnum to gain access to a patch of Sundew, which seen between the eye and the sun at rising, mid-day, or setting, its marvellous hairs and carnivorous teeth of crimson velvet arrayed in hundreds of pretty little pearly stars, the whole plant studded with dewdrops or their likeness; the mind not enraptured beholding in amazement and lifted in adoration will see no grace in the agile creeping of the adder, the perfection of serpentine form in its swimming, and its inimitable colours bright and gaudy as those of its foe the peacock, the two not living in company any more than the lock of Nature can see beauty in plants cut, clipped, and trained into form anything but natural.

Everyone may not be privileged to take moor air; distance may be an object, and right to view if there a deterrent; but there is no reason in the world why there should not be beds of Heather in every garden. Few American grounds have clumps of Heath; they have place probably as a border or hedge, and occasionally Heaths are employed as rock plants. In any form they are desirable; but there are few pleasure grounds in which suitable positions could not be found for a mass or masses of these highly decorative plants, for they bloom at a time when most shrubs have passed flowering, having nothing beyond the foliage of interest. The foliage of the Heath is fittingly contrasting with bolder foliage; indeed nothing is so monotonous as an American ground composed of Rhododendrons only, there being little or no variety in form or tint of foliage, it being only when in blossom that the monotony is varied by different shades of colour; but if we introduce Heaths, Ledums, Gaultherias, and Andromeda we obtain variety in form in time of flowering, and harmonising contrast both of foliage and flower.

Many are kept from growing Heathblooms from the supposed necessity for peat soil. Naturally they are found growing in peat, but it is by no means apparent that peat soil is the cause of our moors being covered with Heather, the evidence is all the other way; the substance known as heath-mould being the *débris* of successive generations of the decayed plants. Either Heathblooms have the power of changing the soil in which they have for any length of time been established into peat by the decay of their fibres, a progressive addition being made to the surface by the decay of the fallen foliage, and an hypothesis supported by the fact that where there is any depth of peat with a growth of Heather the surface is devoid of silicious substances, whilst only a little from the surface the soil contains often considerable silicious particles—sand or flint, according to the formation; the upper stratum is a result of the *débris* of the foliage or part above ground, and the under of that of the decayed fibres. Or we must arrive at the contrary hypothesis, that the peaty formation is due to prehistoric vegetation—*débris* of a vegetable character, which may have been that resulting of a forest—an accumulation of leaves converted into mould by decomposition, which, however, do not contain much silicious matter, and if lying high is brown in colour and mostly occupied with Bracken—not being peat at all, but vegetable soil, for which all the Heathblooms have a decided preference, providing sand be liberally added, though some brown peats are found supporting a good growth of Heath, and the soil full of its decayed stems; yet it is mostly associated with a growth more or less of Bracken, as is testified by its rhizomes in the soil. Decomposing vegetable matter is incontestably the life of Heaths, either their own or that of prior vegetation. I know an extensive establishment in whose pleasure grounds the Rhododendron could not be induced to grow in other than prepared soil—peat had from a considerable distance, and they in the course of a few years even in peat became very unhealthy. The soil was light and sandy, and though trees and shrubs succeeded, the Heathblooms did not, neither there nor in adjacent grounds. Nevertheless in the same formation of soil the vicarage garden had its healthy groups of Rhododendron and upon the lawn a luxuriant mass of Heather; those very subjects in the grounds of the squire, baronet, and lord were very bare of foliage, unsightly objects. The success of the vicar was due to peat. By no means, for the only peat used was that brought with the Heather 2 or 3 inches thick from a moor a dozen miles distant. The whole secret was in the vicar having taken the *débris* from a wood of the squire, and mixed with it about a sixth of sand. The leaf soil, for it was nothing less or more, was put on about a foot thick, and mixed with that depth of the soil of the grounds. This raised the beds or groups considerably, adding immensely to their appearance. The wood from which the vicar had the soil that made his grounds resplendent with Heathblooms was thirty years after planted with Rhododendrons beneath Oaks of, judging from a felled tree, two hundred or more years' growth, harbouring a great

number of rooks, which at the former date were kept from increasing by the wanton destruction of the young; rook-shooting days being greatly in vogue at that time—the time when the Potato disease first became so prevalent in this country; but now not a rook is allowed to be shot in that wood, a great one, with no better cover for pheasants than is formed by Rhododendrons. The ground where was a mass of Daffodils in spring, and a blaze of colour of deeper hue in early summer, to wander through which with the rooks cawing overhead must be cheering to the proprietor—a satisfaction that he is preserving for the good of himself, his tenants, and country the most useful of British birds. But for our land-owners the rook would long ago have become extinct. I mention this because of the dread some appear to entertain of the introduction of the Colorado beetle. Only encourage the rook, and with its aid and our climate between them not a single beetle will survive the year of its advent. The starling, too, would no doubt help to rid the ground of the larvæ; but there is little to be expected from him with the insect upon the plant, as the food of the starling is always sought for in the open; he must see all around.

But I will return to the Heathblooms, for which peat is not essential; indeed most peats, so called, are slow but sure poison for a majority of hardwooded plants. I write this guardedly, for though I have access to miles of moor, high and low, I find it very unsuitable for this particular class of plants: hence the supply of peat *alias* leaf soil; brown and light is procured from a distance. Our home-made leaf soil is black when rotten, but that bought is brown—no more like moor peat than rock is like clay. It resembles cocoa refuse more than anything else, and that material when about half decayed and highly compressed is a very similar material.

Setting peats aside for the present, for which not a necessity arises, to successfully cultivate the various kinds of hardy Heaths, they thriving in most good garden soils, all that is wanted is an open airy situation and the soil freed of stagnant water. If a clump is to be formed on grass the only thing we do is to turn in the turf about 4 inches, and upon this the Heather is placed, it being cut with about 2 inches of soil, selecting the Heather where about 6 inches high. The bed or clump is simply turfed over, and we have a miniature moor at once which for beauty and sweetness is in its season unrivalled. Any time in autumn, winter, and spring in mild weather a group of Heather may be formed. I would advise those contemplating growing Heather to procure it in the turf state, and it grows as surely as grass turf upon a lawn; but I have seen the Heather planted in a sort of inoculation form patches of Heath about 9 to 12 inches square at that or greater distances apart, in which case it is necessary to let them into the ground to the extent of the thickness of the Heath turves. We have several clumps formed in that manner, they in a few years covering the whole surface, but it has, as compared with a clump wholly planted at first, a lumpy appearance. There is that in its favour, that it requires less Heather.

In forming a clump of Heaths where there is no turf I have found it desirable after digging the ground, after pegging out the form, to give it a coat of turfy loam, adding a third of cocoa refuse and a sixth of sand, a 3-inch thickness of which will secure the growth of all the Heathblooms. We can plant according to taste, either having isolated groups of one kind or variety in one; yet it is advisable not to fritter material away by isolation, which grouped or massed is most distinct and effective. The different varieties of *Erica* (*Calluna*) *vulgaris* afford material for a group, the body being the common Heather, and the varieties irregularly disposed on the margin, but always divided by the species from another variety; or a large clump may be formed of the species and smaller detached ones of the varieties, but with some connecting link between them. The species is more tall-growing than the varieties except *E. vulgaris* Alporti, and should therefore form the centre, whether of a group if all in one, or of groups if the species and varieties are detached. There is some variety in colour of flower as also of foliage with diversity of form of plant, so that we have with a similarity of plant great diversity. The species *E. vulgaris*, pale purple; the red, *rubra*; scarlet, *coccinea*; white, *alba*, both in the tall and dwarf (minor) form. Then we have gold, *aureo-variegata*; silver, *argenteo-variegata*; and the downy in tomentosa, the bush form in *dumosa*, and the upright in *stricta*, with dwarfness in *nana*, and a mere pigmy in *pygmaea*.

The Grey Heath (*E. cinerea*) with its white, dark purple, red, and flesh-coloured varieties are subjects for another group

or groups. *E. tetralix alba*, vars. *carnea* and *rubra*, are desirable as forming another group, and the Cornish (*E. vagans*) with its varieties *alba* and *rubra*, giving us the fourth group of natives, to which we can add *E. Mackayana* and its var. *carnea*; the French *E. multiflora*, vars. *alba* and *rubra*, and make up a seventh group with the Portugal (*E. ciliaris*).

With the preceding plants very effective heatheries may be made, either in groups of a species and its varieties, or separate beds of the varieties themselves. They are to be recommended for country residences when there is little in shrubs that is effective, and not a great deal in herbaceous plants but what is at any time liable to be washed out by heavy rains. Heaths require little care. Weeds must of course be kept under, and a little pruning will occasionally be required to keep them in form, which should be done before they commence growing.

Omission must not be made of the very beautiful Irish Heath, the most lovely of all; the white (*Menziesia polifolia alba*); its dwarf form (*M. pumila stricta alba*) forms a fine mass; also the purple (*atro-purpurea*).

Heaths are natives of Europe—*i.e.*, the hardy kinds, though generally classed with American from the supposition that they, being associated with peat soil, thrive under similar conditions. The American plants proper do not thrive in bleak exposed situations, but Heaths delight in mountain air. There is one similarity, however, between them—*viz.*, they all succeed in the atmosphere of towns.—G. ABBEY.

VARIORUM—AUTUMN ROSES, PLANTING, &c.

THERE is a world of wisdom in the trite proverb, "*Qui s'ex-cuse s'accuse*," so I will not deprecate like "WYLD SAVAGE" (although in his case always needlessly) the trial I am about to inflict upon my possible readers, but I will at once say that the sight of my old friend's initials, "C. P. P.," in his useful paper in a recent Journal has been to me as "ointment to sore eyes"—in a highly personal sense, too, having a severe influenza cold—and nerved me to send you a few lines generally under the same heading, "Autumn Roses."

It must, I believe, be generally confessed that La France easily would gain the pride of place if Mr. Hinton were ever to make an election of autumn Roses; but in addition to this indispensable variety I mention a list of other Roses almost certain to give me good blooms in September:—H.P. Exposition de Brie (I include this Rose's three brethren), Sénateur Vaisse, Baronne de Rothschild, Alfred Colomb, Horace Vernet, Xavier Olibo, Mdle. Victor Verdier, Emilie Hausburg, Lyon-naise, Jules Margottin, Duchesse de Morny, Louis Van Houtte. Among these Xavier Olibo and Horace Vernet have been superb, while among Noisettes and Teas Triomphe de Rennes, Céline Forestier, Niphetos, Madame Berard, Alba Rosea, and Catherine Mermet have given me second blooms more glorious than I ever remember before.

I hope few, if any, of my brother rosarians have been hit so hard as I have been by over-manuring this year. Of course so unusually wet a year might upset the very best calculations; but I must come to the conclusion, after the experience of two or three decades, that no stimulating materials can be given with perfect safety except in a liquid state or as top-dressing after the plants are once placed *in situ*, and even there applications must never be given without due consideration as to time and other circumstances.

I should just like to say a word also about that important subject of planting Roses. I may be wrong, of course, but I believe most of us plant our Roses too soon. There are many reasons which prompt to early planting, especially taking the first advantage of the ground working well to get one's plants properly established before the winter, and a still more feasible reason is that unless Roses are secured early from the leading nurserymen the chances are all the best varieties will be sold out. Of course this difficulty will remain to those who like myself advocate, whatever may be the soil or climate, late planting. The Rose I believe entirely ceases from all growth—hibernates (if I may use thus the word) but for a very few weeks, and so if the weather permit I recommend the week after Christmas or thereabouts—the first open season afterwards in fact—to plant out, as giving hardly if any check to the constitution; a very important fact, especially as Roses are grown now-a-days so precociously gross and large that it oftener takes three than two years for the plants to recover moving. Among new Hybrid Perpetual Roses La Rosière, Madame Prosper Langier, Abel Carrière, and Monsieur Tout-nier are alone to be recommended as real tried acquisitions.

Among Teas Madame Léon de St. Jean is most probably a great addition, but new good Teas are still *rare aves*.—HEREFORDSHIRE INCUMBENT.

POTATOES ON A LIGHT SOIL.

ONCE upon a time, not many years ago, I found an old man planting kidney Potatoes. "How do you plant your Potatoes, my friend?" I said. "I plants 'em whole, sir, with a little bit off the end," said he. Rather Irish I thought, but believe he was right in his practice, for sometimes the old Potato does not decay, and if so the produce is not so good. Considerable difficulty has been experienced by the grower of Potatoes on light soils here of late years. If you plant early you encounter Charybdis in the shape of frost; on the other hand, if you plant late you run against the Scylla of drought; or, if you manage to steer your bark clear of both those obstacles you are very likely landed in the Styx of disease. In 1872 and 1873 Potatoes here were very much injured by frost in the early spring, so much so that many persons were induced to plant later than usual in 1874, but it did not answer. In that year drought set in early, and the crop of early Potatoes was consequently very poor.

I thought this year I would try a few experiments to endeavour to find out a way of producing better results. In the middle of February I had a small plot of land planted with the Morning Star Potato (an early kidney). The sets were not shot out at all, and were planted 5 inches deep. In the middle of March I had another plot planted with the same kind of Potato, with sprouts about an inch long, also 5 inches deep. At the end of March another lot was planted at same depth; at the beginning of April another only 3 inches deep; the last lot was planted at the end of April 3 inches deep.

My man prophesied that the first lot would never come up, but they did with the exception of two. All the plots came up very well. The second was the most forward, and the Potatoes were protected from the frost early in May by some straw spread along the rows directly they could be seen. They may be protected by earthing-up the soil, but that does not answer if the land is wet at the time.

All the plots looked very well in the early summer, and were all the better for the little manure which was put in with the previous crop; but the weather in June was very dry, and if rain had not come in the early part of July the later-planted would not have been worth much.

The second plot was the most forward at digging-up time, the first and third were about ready together. The crop was good, and they were dug-up before the appearance of disease. The fourth and fifth lots did not come until all danger of frost was over, but were overtaken by disease. The fourth was consumed before many were lost, but the fifth lot was badly diseased. An attempt was made to save them by removing the tops. The operator sets a foot on each side of the haulm and it is drawn out. In this case it was not successful, and ought, perhaps, to have been done earlier; and the quality of the Potatoes suffered so much from the removal of the tops that they were almost uneatable, but improved by remaining in the ground. When dug-up at the end of August about half of the last plot were lost by disease. Perhaps we ought not to draw conclusions from a single experiment, but try again over a series of years.

There are, however, one or two things which are confirmed by previous observation. It is by no means desirable to plant late in this district. The middle or end of March is the best time, and more care and thought must be given to protection in May than has been hitherto done. If you carry out this and put in a good breadth of early sorts the loss by disease is much curtailed.

I think the early Potatoes here are planted too near the surface, particularly when planted in good time, and I think the deeper have the following advantages:—They do not come-up so soon, they are more sheltered from the rays of the sun, and as the diseased Potatoes are generally nearest the top not so liable to disease, but this latter part requires further observation.

It is certainly rather singular that the disease should have prevailed for more than thirty years, and that no one should have discovered any remedy, and that differences of opinion should still exist as to what was the origin of the disease. The experiment has been tried of importing Potatoes from Peru, thinking that the cultivated varieties were rendered delicate and that others would escape, but the Peruvians were as bad as any.

I am inclined to the view that the Potato disease is very much the same as the zymotic disease in the human subject, and more care ought to be taken to prevent the spread of it by contagion. The rotten Potatoes, I think, ought not to be left on the land to taint the atmosphere as they usually are, but collected and boiled for pigs or burnt. Not long ago I sent you a short review of an essay in the Royal Agricultural Society's Journal by Professor de Bary on the Potato fungus, in which I recommended the experiment to be tried of planting Potatoes, which were perfectly free from disease when dug up, in a field away from any human habitation. If any of your correspondents have done so this year I should be glad to hear the result.—AMATEUR, Cirencester.

CARLISLE INTERNATIONAL SHOW.

SEPTEMBER 6TH, 7TH, AND 8TH.

CARLISLE may fairly be said to be a city of contests. Almost from time immemorial it has been the scene of contention in turn by Roman, Dane, Saxon, Norman, Scot, and its own brave burghers. Fire, and sword, and famine, and capitulation have all in turn had the ascendancy; triumph and humiliation have in turn prevailed. Yet notwithstanding the strife of centuries no city in the realm is more peaceful, more industrious, than Carlisle is now, for neatness, thrift, and cleanliness prevail everywhere; the storm of contending passions has spent itself, and the calm of reason, contentment, and prosperity rules. But not the calm of inactivity. No, Carlisle—contestant Carlisle—must have its tournament of peace as it has had its struggles of war. The last contest has been worthy of the border city, a contest if not so exciting yet immeasurably more commendable than others which are chronicled in history—a contest of peace, industry, skill, and refinement, where old friends have met in honest rivalry and remain friends still; where new acquaintances have been made, latent effort stimulated, and another impetus has been given to horticultural work.

The last contest has demanded the same qualities which were exercised so remarkably in the past—energy, resource, and endurance. Was not energy required when a small city of thirty thousand inhabitants essayed to provide a gathering equal to any similar gathering of the past—an International Horticultural Show? Was not resource necessary in making the arrangements so complete? Was not endurance needed to have the immense display arranged and judged two hours after sunrise on the first day of the Show? Let those answer who saw the work being done. It was a work of day and night continually to do so much as was done in the preparations for and conduct of this great Show. Projected only a year ago, it has been carried-out successfully. All who could do so have aided in the work: The Corporation, by placing the fine site at the disposal of the Committee and providing other facilities; the affluent of the district and the tradesmen of the town, by contributing in a liberal, in some instances a spirited manner, towards the Show fund; and the Executive Committee, by arduous and well-directed labour.

The site of the Show was admirable. On the one hand the frowning warlike Castle, on the other the peaceful and beautiful river Eden. There are the natural boundaries of the pasturage known as the Sawceries. About thirty-five acres were enclosed. The great industry of horticulture was exemplified in its various phases—mechanically by glass structures, boilers, machines, manures, tools, and requisites; culturally by the splendid examples of skill displayed in the tents. The tents, yes, these demand a passing notice both on account of their extent and manner of arrangement. A finer display of canvas was never seen at any horticultural show. Its cost alone, independent of its fittings of gas and hot-water pipes, was £600. Its extent was approximately as follows:—A covered way of considerable length conducted to the specimen-plant marquee, which was 300 feet long by 50 feet wide. This terminated in a central pavilion-like marquee, lofty and circular, and nearly 100 feet in diameter. From this central point other branches radiated—one to the north about 100 feet in length for cut flowers, another to the west 300 feet long for fruit, and a third to the south 450 feet long by 50 feet wide, chiefly for the nursery-men's collections of plants; in addition, yet isolated, was a large marquee for the display of vegetables. Such was the extent and disposition of the tents, we will now refer to their contents and to the honours won by the several competitors.

But were the tents filled? Yes, fairly well. At one time it appeared impossible to fill them, as so many who had entered failed to occupy their space. Was the Show a success? Doubtful, extremely so. Writing on the opening day and before the opening hour, the prospects look gloomy enough. Everything under control had been done to bring the undertaking to a satisfactory issue, but an element beyond control asserted its power

in a forcible, almost a violent manner. Immediately the judging commenced the rain commenced too, and continued pouring incessantly—a perfect torrent for hour after hour, making the ground a quagmire, penetrating the tents, converting the sawdust into mortar, and rendering planks necessary at and within the entrance of the marquees. Those who were present will not soon forget the baptism of the International Show at Carlisle on the eventful morning of September 6th. In referring to the classes we may follow somewhat the order of the schedule, and commence with

FRUIT.

While many good collections and excellent examples of culture were staged, the display was not on the whole equal to those provided either at Dundee last year nor at Edinburgh in 1875, nor yet, except perhaps in the classes for Grapes, to exhibitions we have seen at South Kensington and at the two Palaces at Sydenham and Muswell Hill. A season of extraordinary inclemency has prevailed in the north: rain, and cloud, and cold have ruled supreme, and the wonder is that the ordeal has been passed through so well as it has been; but even that is not a sufficient reason for the staging of much fruit, especially Grapes, which were at once the strong and the weak feature of the Show, and which compelled the Judges, stern men and competent—Mr. David Thomson of Drumlanrig, and Mr. Barron of Chiswick—to withhold some of the prizes. They did right, and have set a wholesome example, for a prize should never be given unless to a subject of intrinsic merit.

COLLECTIONS OF FRUIT.—In the premier class of sixteen sorts prizes of £20, £15, £10, and £5 were provided, but only three collections were staged; Mr. Hunter of Lambton, who had entered, not competing. The prizes were awarded in the following order:—First to Mr. Coleman, gardener to Earl Somers, Eastnor Castle; second to Mr. Johnstone, gardener to the Earl of Strathmore, Glamis Castle; and third to Mr. Ingram, gardener to the Duke of Northumberland, Alnwick Castle. At the first glance Mr. Johnstone's fruit looked the more imposing owing to the superiority, at any rate in size, of the Grapes, but a more careful examination satisfied that Mr. Coleman's fruit throughout was of the greatest general excellence. His collection included two fine and perfectly ripe Pine Apples (Smooth Cayenne and Black Jamaica, excellent Black Morocco Grapes and rather small but well-finished Black Hamburgs, also Alicantes and Madresfield Courts; splendid Golden Gem and a fine Eastnor Castle Melon, Bellegarde and Crimson Gaiety Peaches, Pitmaston Orange and Elrude Nectarines, Brown Turkey Figs, Diamond Plums, and Morello Cherries, all of superior quality. Mr. Johnstone had splendid Grapes—Muscats of Alexandria, Alicante, Black Hamburg, and Gros Guillaume; but his Pines were not ripe, and Peaches, Nectarines, Plums, and Figs were rather small. Mr. Ingram had capital Trebbiano, Muscat of Alexandria, and Black Hamburg Grapes, and rather small Lady Downe's; excellent Pines, an unripe cluster of Bananas, two fine Melons, Peaches, Nectarines, Oranges, and Cherries.

In the class for twelve sorts of fruit there were seven entries, Mr. Wallis, gardener to Sir Henry Thompson, Bart., Kirkby Hall, York, winning the premier place with Muscat of Alexandria, Black Hamburg, Muscat Hamburg, and Buckland Sweetwater Grapes, all of excellent table quality; two Melons, Gilbert's Green-flesh being very fine; and excellent Royal George and Barrington Peaches, Nectarines, Figs, and Apricots. Mr. McKelvie, gardener to the Duke of Roxburgh, Broxmouth Park, Dunbar, was second with splendid Muscat of Alexandria and other fine Grapes, rather coarse Melons, and smaller fruits generally good. Mr. Upjohn, gardener to the Earl of Ellesmere, Worsley Hall, Manchester, was third with very good Grapes and Melons, but his other fruits were not quite ripe; and Mr. Dickson, gardener to J. Whyte-Melville, Esq., Mount Melville, St. Andrews, fourth, his most noticeable dishes being fine Buckland Sweetwater Grapes and good Peaches and Oranges. For ten sorts of fruit, Grapes and Pines excluded, there were only two competitors—Mr. Shand, gardener to the Earl of Lonsdale, Lowther Castle, Penrith, and Mr. Graham, gardener to J. Allan, Esq., Craigburn, Moffat, who were placed as named. Mr. Shand had excellent Peaches and Nectarines, very fine Apricots, and excellent Plums, Gooseberries, and Cherries, all ripe and in capital condition; Mr. Graham's fruit was also good, but some of it was not fully ripe.

PINES.—These were not numerous, nor, except the winners, good. Mr. Ingram won first honours in the class for two Queens with well-ripened fruits weighing about 5 lbs. each; Mr. Sandford, gardener to the Earl of Beattie, being placed second; and Mr. Halliday, gardener to Mrs. Wemyss, Wemyss Court, Dysart, third with smaller fruit. In the class for any other sort Mr. Coleman won with Black Jamaica; and for the heaviest fruits Mr. Sandford was placed first with unripe Smooth Cayennes weighing about 6 lbs.

GRAPES.—There were four entries in the class for eight varieties. Mr. Reid, gardener to A. H. Moncur, Esq., Rockfield, Dundee, worthily won the first position with a medium-sized bunch of Alicante in splendid condition; Lady Downe's with

extra fine berries; Muscat Hamburg, very full and well finished; Gros Guillaume, weighing 8 or 9 lbs. and nearly black; Muscat of Alexandria, very superior; Mrs. Pince, fine but not well coloured; medium-sized and good Black Hamburgs and Gros Colman, fine in berry but not quite ripe—an admirable collection. Messrs. Lane & Son, Great Berkhamstead, were placed second with superior Muscats of Alexandria, very good Golden Queen, Alicante, Trebbiano, Bowood Muscat (very compact), and excellent Black Hamburgs. The third prize appeared to have been withheld, and a fourth was awarded to Mr. Halliday, whose bunches had been much injured in transit.

In the class for four varieties there were fourteen competitors. Mr. Hammond, gardener to Sir Wilfred Lawson, Bart., Brayton Hall, Carlisle, won with very finely finished but unnamed examples of Black Hamburg, Buckland Sweetwater, Golden Champion (splendid), and Alicante. Mr. Coleman was second with Black Hamburgs in the true Eastnor style; Black Morocco, full and fine but not quite ripe; and excellent Buckland Sweetwater and Madresfield Court. Mr. Kirk, gardener to Mrs. Mackie, Enspil House, Castle Douglas, was placed third with very good examples of Duke of Buccleuch, Black Hamburg, Buckland Sweetwater, and Alicante—large bunches, but much rubbed in transit; and Mr. Curror, gardener to G. Douglas, Esq., Eskbank, Dalkeith, fourth with fine bunches but not fully ripe.

In the class for two bunches of Black Hamburg Mr. Coleman won the silver cup offered by Messrs. James Boyd & Son, Paisley, with splendid examples, fine in size of berry and of excellent finish, the bunches weighing about 3 lbs.; Mr. Upjohn being second with fine full bunches, but not quite jet black. Mr. Fraser, Stobbo Castle, Peebleshire, third with capital fruit, but a trifle deficient in colour; and Mr. Harrison, Knowsley, fourth, with large bunches but rather small berries. There were twelve competitors. In the class for two bunches of Muscat Hamburg five competed. Messrs. Lane & Son were first for very full and finely finished bunches; Mr. Smith, gardener to the Countess of Stair, Bargany, Girvan, second with excellent produce; and Mr. Bloxham, gardener to Sir P. Duncombe, Brickhill Manor, Bletchley, third with capital bunches but not fully ripe. Mr. Fraser, Stobbo, won in the Madresfield Court class with medium-sized bunches of remarkable finish, and which had been thinned by a master hand. The second award had no exhibitor's name attached, and the third went to Mr. Bruce, gardener to J. Fildes, Esq., Chorlton-cum-Hardy, Manchester, good in bunch and berry but not quite ripe. Some very inferior produce was exhibited in this class. Mr. Hammond worthily won the first place with Alicantes—splendid in bunch, berry, and bloom; indeed, finer examples have rarely been seen. Mr. Curror was second with compact well-finished bunches, but rather small berries; and Mr. Ferguson, gardener to B. Shaw, Esq., Carrick Hall, Selby, third with large bunches and black berries, but rubbed in transit. There were ten competitors. Mr. Hammond, who exhibited well throughout the Show, was first with Lady Downe's, bunches medium size and berries extremely fine, but not at their best—not quite ripe; Mr. Fraser, Stobbo, who is evidently a first-rate cultivator, was second with excellent examples; and Mr. Ferguson third with large but rather loose bunches, which had been somewhat injured in transmission to the Show. Mr. Reid won with Mrs. Pince—thus securing the silver tea service, value £6 6s., offered by Messrs. Mackenzie and Moncur—good and admirably thinned bunches, and nearly black; Mr. Hammond was second with good bunches, Mr. Bruce third, and Mr. Ingram fourth, but none of them were well coloured. In the class for any other variety of Black Grapes Mr. Hammond won with extra fine Gros Colmans; Mr. Ferguson being second with the same variety, but not quite black; and Mr. Leyden, gardener to R. B. Wardlaw-Ramsay, Esq., Whitehill, Edinburgh, third with capital examples of Black Prince, about 4 lbs. in weight and well finished; they almost merited a higher position.

We now come to the white varieties, and have to note some of the best and worst Grapes in the Exhibition. The class for Muscat of Alexandria (two bunches) was an excellent one. There were eighteen competitors. Mr. McKelvie won the premier place with handsomely-formed bunches of 5 or 6 lbs. weight, with fine and highly finished berries without spot or blemish; Mr. Ferguson was second with excellent examples, regular and full; and Mr. Coleman third with capital bunches, clear and well finished. Messrs. W. Thomson & Son, Tweed Vineyard, Clovenfords, won in the Duke of Buccleuch class with medium-sized bunches and very fine, regular, and clear berries; and Mr. Curror was second with still finer berries, but slightly spotted. The third prize was very properly withheld. In the class for any other white variety Mr. Curror won with capital examples of Buckland Sweetwater; Mr. Anderson, gardener to the Earl of Stair, Oxenford Castle, Dalkeith, was second with Pearson's Golden Queen, regular and fine, but slightly rusted and rather dull; and Mr. Upjohn was third with large bunches of Trebbiano, but the berries were not clear.

Single bunches, Black Hamburgs, seven competitors. The first prize of £3 3s. was offered by Mr. David Lowe, Edinburgh,

but it was rightly withheld. Third and fourth awards were made to Mr. Reid, gardener to D. Barrie, Esq., Elmbank, Dumfries, and Mr. Kirk, Ernsapie House, Castle Douglas. A wretchedly poor class. Alicantes.—First Mr. Masson, Marchmont, Dumfries; bunch medium, berries good. Second Mr. Paterson, Dryfeholme, Lockerbie; poor bunch, very fine berries. Third Mr. Peel, gardener to E. P. Sheldon, Esq., Carlisle. Lady Downe's.—First Mr. Reid, Rockfield; fairly good. Third, Mr. Dickson, Arkleton; not ripe. Gros Guillaume.—First Mr. Ferguson; bunch large, berries small but well coloured. Third Mr. Bruce. Muscat Hamburgh.—First withheld; second Mr. Paterson; third Mr. Reid, Elmbank—a poor class. In the next four classes for one bunch of any black Grapes, one of Muscat of Alexandria, one of Golden Champion, and one of Canon Hall Muscat, the Judges knew their business too well to award any prizes. In the class for any other sort of white Grapes Mr. Kirk won with a remarkably fine forked bunch of Buckland Sweetwater weighing 6 or 7 lbs., full and clean, and well worthy of its prize. Mr. Miles, Wycombe Abbey, was second with a good tapering bunch of Trebbiano weighing 4½ lbs., and Mr. Paterson third with Buckland Sweetwater.

In the heaviest-bunch class we have nothing sensational to record. Mr. Dickson, gardener to J. Jardine, Esq., Arkleton, who during a series of years has exhibited so remarkably in this class, won with to him a small bunch of Syrian weighing 9 lbs. 23 ozs.; and in the corresponding class for black Grapes he won with a Black Alicante weighing 6 lbs. 13 ozs.

In the next class, for one bunch not less than 1 lb. in weight having the finest bloom, there were seventeen competitors. A few of the bunches were indifferent, but others, especially the prizewinners, were excellent. The premier prize was won by Mr. Lees, gardener to the Marquis of Downshire, Hillsborough Castle, Co. Down, with a well-shaped medium-sized bunch of Cooper's Black. The berries were faultless in appearance, carrying a fine bluish-black bloom of great intensity. Mr. Curror, Eskbank, was second with a densely coloured bunch of Alicante, and Mr. Masson was third with the same variety.

MELONS.—About two dozen of fruits were staged. They were not of extraordinary excellence, but were generally superior to Melons which have been exhibited in the south during the past two years. In the green-fleshed class Mr. Coleman was first with a handsome and excellent fruit of Eastnor Castle; Mr. Kinnaid, gardener to T. H. Graham, Esq., Edmond Castle, second; and Mr. Sandford third. In the scarlet-fleshed section Mr. Halliday, Wemyss Castle, was first with a seedling of extra rich flavour; Mr. Sandford second; and Mr. Leslie, gardener to W. Maxwell, Esq., Dalbeattie, third. Mr. Kemp, gardener to J. Dalrymple, Esq., Langlee, Galashiels, exhibited an oval-shaped deeply ribbed fruit weighing 14 lbs. 11 ozs., which was highly commended; and Mr. O. Tyler, Hassobury, Bishop Stortford, Herts, exhibited a new variety named President, one of the most promising Melons that has lately been submitted for public adjudication. The fruit is round, medium-sized, and handsomely netted; flesh rather firm yet melting, very juicy, and of remarkable richness. It was awarded a first-class certificate.

In the class for Figs Mr. Halliday, gardener to the Earl of Mansfield, won with an excellent dish of the White Genoa, Mr. Coleman being second with capital examples of Brown Turkey, and Mr. Paterson third.

PEACHES.—The show of this fruit was only of moderate extent, but some capital dishes were staged. In the class for twelve fruits in two varieties Mr. Leydon won with Barrington and Noblesse, fine both in size and colour. Mr. Fox, Carnforth, was second with Bellegarde and Royal George, and Mr. Dickson, Arkleton, third with Royal George and Noblesse. For dishes of six fruits there were ten competitors. Mr. McFarlane, gardener to T. Pilkington, Esq., Knowsley Cottage, Prescot, won with a very fine dish of Barrington. Mr. Fox was second, and Mr. Lees, Hillsborough Castle, third with the same variety.

NECTARINES.—The principal prizetakers were Mr. Hannagan, Hooton Hall, Chester, Mr. Dickson, Arkleton, and Mr. Craig, Wykeham Abbey, York, who were placed in the order of their names with creditable dishes.

PEARS AND APPLES, with the exception of the Royal and the foreign collections, were not noteworthy. For twenty varieties, two fruits each, ripe or unripe, Mr. Jones, gardener to Her Majesty the Queen, Frogmore, was far in advance of the other competitors. He staged admirable examples of Beurré Bachelier, Madame Trevey, British Queen, Vicar of Winkfield, Chancellor, Beurré Bose, Victoria, Beurré Rance, Kingessing, Beurré Clairgeau, Beurré Benoit, Marie Louise, Conseiller de la Cour, Williams' Duchesse, Autumn Nelis, Williams' Bon Chrétien, Van Mons Léon Leclerc, Doyenné Boussoch, Beurré Diel, Brockworth Park. Messrs. Gellender & Sons, Newcastle, had the second, and Mr. Miles the third prize. In the corresponding collection of Apples Mr. Jones was similarly in advance of his rivals with the following good varieties:—Flower of Herts, Ecklinville, Braddick's Nonpareil, Hawthornden, Boston Russet, Wellington, Blenheim Pippin, Old Orange Pippin, Ribston

Pippin, Rosemary Russet, King of the Pippins, Cox's Pomona, Hollandbury, Waltham Abbey Seedling, Hoary Morning, Duke of Gloucester, Frogmore Prolific, Brown's Seedling, Betty Geeson, Frogmore Seedling (No. 1). Mr. Miles had the second prize for a capital collection. The first prize of £15 for a collection of Apples and Pears of foreign growth was won by Mr. Adolphe D. Heine of Ghent with upwards of fifty varieties of Pears and thirty of Apples. These collections prevented the title of the Show, "International," from being a misnomer. They were good, but not equal to the Frogmore collections. Plums were very scantily exhibited. The chief prizewinners were Mr. Dickson, Arkleton, and Mr. McKelvie, who staged good dishes. Gooseberries and Currants were good, a dish of the Red Currant La Versailles from Mr. Wallis, Kirkby Hall, being very fine.

The special prizes of £5, £3, and £2, offered by J. Jardine, Esq., of Arkleton, for eight varieties of hardy fruit, brought out seven admirable collections. The first prize was won by Mr. Sandford, gardener to the Earl of Bective, with Plums (two varieties), Pears, Apples, Peaches, Gooseberries, Currants, and Cherries. Messrs. Turner Bros., Liverpool, were second, and Mr. Yonds, Scotby, third.

Only one other collection of fruit demands notice—namely, a collection of British-grown fruit of the Orange tribe. This was contributed by Mr. Muir, gardener to C. R. M. Talbot, Esq., M.P., Margam Park, Glamorganshire. Ten varieties were staged—Citrons, Shaddocks, Lemons in two and Oranges in six varieties, the largest exhibit we remember seeing of this character, and an extra prize was worthily awarded.

PLANTS.

Although the spread of fruit was not equal to that of former northern displays known as international, yet the collections of plants at Carlisle far surpassed those of either Dundee or Edinburgh. Many grand specimens were staged in competition, and remarkably good and extensive miscellaneous groups were arranged by the nurserymen.

In the nurserymen's class for twenty stove and greenhouse plants the £20 prize was won by Mr. Troughton, manager to the Preston Nursery and Pleasure Garden Company, with an excellent and admirably arranged group. In the centre were three Tree Ferns, on each side of which were capital specimens of *Lapageria rosea* on a 5-feet globe, *Cycas circinalis*, a splendid plant; *Dion edule*; *Eurya latifolia variegata*, oval-shaped, 5 feet high, effective; *Areca amula*, &c. The second prize of £15 went to Messrs. J. & R. Thyne, Glasgow, who also arranged a capital collection, including a very fine *Areca Baweri*, *Cyathia Burkei*, *Astrocaryum mexicanum*, *Latania borbonica*, *Cycas revoluta*, brightened with such plants as *Croton Johannis* in splendid colour, *Pancratium grandiflorum*, and *Heaths*; a remarkably fine specimen of *Adiantum cuneatum* was included in this group. Messrs. Clark, Bros., Carlisle, were awarded the remaining prize for a creditable collection.

In the class for six Orchids in bloom Mr. B. S. Williams, Victoria and Paradise Nurseries, Holloway, was easily first. He staged a very good and remarkably attractive specimen of *Oncidium Marshallii* with six fine spikes, *Odontoglossum Alexandræ fimbriatum*, an exceedingly fine variety of this fine Orchid; *Cypripedium Sedeni*, *Vanda suavis*, and *Odontoglossum Reicheneitii*. Mr. Pattinson, St. Ann's Hill, Carlisle, was awarded the second prize. In the class for ten exotic Ferns the prizes went to the Preston Nursery Company, Messrs. J. & R. Thyne, and Mr. James Service, Maxwelltown, Dumfries, in the order named, who each exhibited good collections, which were arranged in circular groups in the central pavilion tent. The Tree Ferns were also placed in this tent between the other groups. The chief prizes went to Messrs. James Dickson & Sons, Newton Nurseries, Chester, with very tall *Dicksonias*, and Messrs. J. & R. Thyne with *Cyathia medularis*.

In the class for twelve new plants not in commerce the first prize was awarded to Mr. William Bull, King's Road, Chelsea, and second to Mr. B. S. Williams. These collections were much discussed by the visitors, and were generally considered to be of equal excellence; both of them were good. Mr. Bull's plants consisted of *Zamia princeps*, very elegant; *Croton formosum* and *C. triumphans*, stately and bright; *Dieffenbachia Shuttleworthii*, *Alocasia Johnstonii*, *Aralia splendens*, *Bowenia spectabilis serrulata*, *Curmeria Wallisii*, and *Dracena Goldiana*. The Holloway plants were *Croton Prince of Wales*, a fine drooping spiral-leaved variety of good colour; *C. lancifolium* and *C. imperator*, bold and finely coloured; *Dracenas Scottæ*, *superba*, and the beautiful *Banseii*; *Nepenthes phyllamphora variegata*, *Thrinax gracillima*, *Jambosa acida*, *Adiantum Williamsii*, *Cibotium nigrescens*, and *Aralia nobilis*.

CONIFERS.—These were arranged in the open air. Very fine collections were shown by Messrs. W. Barron & Son, The Nurseries, Borrowash, who had the first honours for fifteen varieties; Messrs. Dickson & Turnbull, Perth, who were second; and Messrs. Little & Ballantyne, Carlisle, who had the remaining prize. The last-named firm also exhibited a valuable miscellaneous collection. Messrs. Clark, Bros., also contributed

worthily. For six hardy Conifers introduced during the last six years the awards went to Messrs. Barron & Son, who staged (in the pavilion tent), attractive but necessarily small examples of *Podocarpus alpina*, *Retinospora tetragona aurea* and *R. pisifera aurea*, *Wellingtonia gigantea lutea*, *Picea concolor*, and *Cupressus Lawsoniana elegantissima*. Messrs. Barron also exhibited a large miscellaneous collection of new and rare Conifers, and Mr. G. J. Alberts, Boscoop, Netherlands, a collection of Hollies.

The prizes offered for the best "new Conifer of real merit" was won by Messrs. Little & Ballantyne, with their new weeping *Wellingtonia*, which is well worthy of the distinction. The illustrations which have appeared of this variety do not do justice to it. By no mere manipulation could its branches be tied down so elegantly at the same time the growth is free, almost vigorous. As a graceful columnar specimen for lawn ornamentation this distinct variety is admirably adapted, and can hardly fail to become very popular. This firm and Mr. James Service secured the prizes for collections of alpine plants.

AMATEURS AND GARDENERS.—In this section of the Show there were many plants exhibited of little or no merit, but at the same time there were others which have never been surpassed at any show held at the same period of the year. Where Mr. Shuttleworth the prince of amateur cultivators exhibits, marvellously fine specimens are certain. That gentleman's collection of twelve stove and greenhouse plants, six of them in bloom, which won the £20 prize, was splendid. *Gleichenia diacarpa* and *dichotoma* were 8 to 9 feet in diameter, and in superb health; *Cordylus indivisa* was in remarkable vigour, as was also *Phormium Colensoi variegata*; *Croton majesticum* was 5 feet through and in rich colour; and *Cycas circinalis* was grandly exhibited. Amongst the flowering plants were *Allamanda nobilis*, good; *Dipladenia amabilis*, *Ixora coccinea*, and *Lagerflora alba*, the last-named plant, which covered a 3-foot globe trellis, being not more remarkable for its fine wax-like flowers than for its exuberant foliage; *Statisia imbricata*, 6 feet; and *S. profusa*, 5 feet in diameter, were conspicuous in this fine collection. The second prize, £15, was well won by that excellent cultivator Mr. Todd, gardener to A. B. Stewart, Esq., Rawcliffe, Glasgow; and Mr. Kinnaird, Edmond Castle, was awarded the third prize of £10. In the class for six plants, three of them in bloom, Mr. Hammond (who exhibited as well in the plant as he did in the fruit classes), won with excellent examples of *Vallota purpurea* with thirty spikes, *Allamanda Hendersoni*, *Rondeletia speciosa major*, a *Dasylium*, *Croton*, and very fine *Cocos Weddelliana*. Mr. Shand, The Gardens, Lowther Castle, had the second prize, the notable specimen in the collection being *Lilium lancifolium rubrum* trained much in the way of a specimen *Pelargonium*. This fine example of *Lilium* culture was fully 6 feet in diameter, it had about eighty spikes and quite three hundred expanded and opening flowers. In the class for nine plants in 12-inch pots the prizes went in the following order—to Mr. McIntyre, gardener to A. A. Richardson, Esq., Lisburn, Mr. Hammond, and Mr. Blackwood, Edenhill, Penrith, for good collections. Messrs. Hammond and Todd secured the prizes in the class for six fine-foliaged plants, *Adiantum farleyense* of the first-named exhibitor being in grand condition, and the remainder good. In the next class, for six plants in bloom, some excellent specimens were staged. Mr. Shuttleworth won with *Eucharis amazonica*, 5 feet in diameter and thirty spikes; *Erica Jacksonii*, 2½ feet through; *Ixora coccinea*, *Statisia intermedia* and *profusa*, and *Anthurium Scherzerianum*. Mr. Hammond was second, his *Vallota* being especially fine; and Mr. Shand third, *Lilium lancifolium* again being conspicuous by its excellence. Mr. Shuttleworth won in the class for three Palms with *Cocos Weddelliana*, *Chamærops humilis elegans*, and *Pritchardia pacifica* remarkably fresh. He also won first for the specimen *Todea (Leptopteris) superba* and for eight plants for table decoration, Mr. Todd being second in these classes. Mr. Pratt, gardener to Viscount Hill, Hawkstone Park, Shrewsbury, being third in the table-plant class. All the collections were very good.

Crotons were splendidly shown by Mr. Scott, gardener to G. Steele, Esq., Hill Park, Bothwell, who had the first prize for four varieties, with *C. irregulare* 5 feet in diameter and 6 feet high, probably the best plant in Europe; *C. angustifolium*, a handsome pyramid about 7 to 8 feet high; *C. Weismanni*, a golden globe of 5 feet, and *C. variegata*, a fine pyramid, all in splendid health and colour. Mr. Hammond was second with *C. pictum*, *undulatum*, *Johannis*, and *Weismanni* in admirable colour and condition. Mr. Hammond won first with *Adranas*, which were good, followed by Mr. Blackwood and Mr. Todd; and Messrs. Scott and Todd secured the prizes for hardy Heaths. Ferns were very well exhibited in this section, but *Fuchsias* and *Geraniums* were not of remarkable quality, while *Cockscombs* were rough and *Balsams* poor. In the class for *Liliums* Mr. Shand was well in the ascendant, and Mr. Pattison, Baxter Park, Dundee, staged a choice and well-cultivated collection of Alpine plants. Most of the specimen plants were arranged on a low stage in the centre of the entrance tent, the new plants

and table plants occupying the sides of the great marquee, which was heated for the choice miscellaneous collections of the chief nurserymen. It is fortunate that this marquee was so well heated, or much injury must have resulted during the first cold, wet, and miserable day of the Show. The heating was done by Mr. Corbett, Carlisle, with one of Hartley & Sugden's climax boilers.

The collections of plants in this tent were extensive and rich. The first group, a grand one, one of their very best, was arranged by Messrs. Veitch of London. Pitchers, Orchids, Ferns, Crotons, Aroids, insectivorous plants, &c., were arranged with consummate taste, and were greatly admired; it occupied staging about 40 feet in length by 10 feet wide. Messrs. J. & R. Thyne arranged the next group, which was also about 40 feet in length, then came Mr. Williams's (of Holloway) extensive and fine collection. Here *Croton Queen Victoria* asserted its great decorative power; *C. volutum* and other bright varieties were also represented, associated with Palms, Ferns, Orchids, *Liliums*, *Darlingtonias*, &c., and *Dipladenia Brearleyana* attracted much notice. Messrs. R. P. Kerr & Sons, Aigburth Nursery, Liverpool, arranged a collection of considerable extent and merit, as also did Messrs. Pattinson, St. Ann's Street, Carlisle. Messrs. Ireland & Thomson, Craigleith Nurseries, Edinburgh, arranged an extensive and meritorious collection, including most of the newest and most popular decorative plants in a bright clean state. Noticeable in this group was the dark *St. Martin's Blue Lobelia* with bronze foliage, also two Ferns, *Gymnogramma nævium*, a dwarf and densely powdered variety of *G. peruviana*, and *Adiantum Flemingii*, a fine variety of *A. concinnum*. This is a Fern of great merit; its fronds possess a certain massiveness on account of the closely arranged pinne, while they are elegant by their gracefully arching character. The colour of the fronds is a rich deep green. It appears to be a free grower, and likely to be useful for both exhibition and decorative purposes, also for cutting for bouquets. Messrs. James Dickson and Sons, Newton Nurseries, Chester, staged a large collection of Palms and other decorative plants, also a new seedling form of *Cupressus Lawsoniana*, very compact in habit and silvery in appearance. It was awarded a certificate of merit, and if it goes on improving it will prove a great acquisition.

The above collections were honoured by awards of recognition, and the following plants in the collection of Messrs. Veitch were awarded first-class certificates:—*Cattleya Sedeni*; *Nepenthes hybrida maculata major*, a grand variety; *N. Rafflesiana pallida*, extremely compact; and *Athyrium Goringianum farinosum*, an elegant Fern and very silvery.

In the pavilion tent Messrs. Little & Ballantyne arranged a large central group, and round the sides were collections of market plants from the nurseries of Messrs. Clark, Bros., and Mr. Armstrong—a grand tent, but not artistically arranged. A small adjoining marquee contained some cut flowers, excellent examples of skeletonised leaves from Messrs. Cusson, Southampton, and Hodgkins, Manchester; also a standard *Fuchsia*, the head having been grafted with six different varieties, all flowering well. It was exhibited by Mr. McMillan, Broadmeadows, Berwick-on-Tweed. In the fruit tent was an exhibition of bees, large separate tents being provided for the table decorations and vegetables. Of the cut flowers and decorations a "specialist" must write. Also as yet demanding notice are the

VEGETABLES.—Of these the display was a capital one, but on the whole the examples were fully too large to be considered of the first London quality. Cabbages were immense, Leeks remarkably fine, some being blanched a length of nearly 2 feet; Turnips and Carrots clear and excellent; Cucumbers large, Tender-and-True winning every prize; Curled Kale first-rate, Celery second-rate, Onions third-rate, and Potatoes fourth-rate, or many of them, a few dishes and collections being excellent. The finest round Potato in the Show was Turner's Schoolmaster. The best collection of vegetables was the first-prize tray of Mr. Bloxham, gardener to Sir P. Duncombe. It consisted of Cucumbers, Cauliflowers, Carrots, Potatoes, Onions, Celery, Globe Artichokes, Turnips, Peas, and Kidney Beans, all good. The premier prize for twenty varieties was won by Mr. Sandford, gardener to the Earl of Bective, who had Broad Beans, Vegetable Marrows, Tomatoes, Parsnips, Savoys, Leeks, Cabbages, Brussels Sprouts, Kohl Rabi, and Kale, in addition to the ten varieties above named. Other successful exhibitors of collections were Messrs. Nicholl, gardener to J. A. Corry, Esq., Botcherby; Craig, Wykeham Abbey; Bell, Shand, Younds, and Culton.

Special prizes offered by Mr. Wm. Bull.—First prize, a silver cup, value fifteen guineas, second ten guineas, third six guineas, for twelve new plants introduced and sent out for the first time since the commencement of 1874. First, T. M. Shuttleworth, Esq., Preston, with a splendid collection. Second, Mr. J. Hammond, Brayton, Carlisle. Third, Mr. J. McIntyre, gardener to A. A. Richardson, Esq., Lisburn, Ireland.

In the open-air exhibits we noticed useful greenhouses and serviceable frames from Messrs. Boulton & Paul, Norwich; a capital lean-to house with rafter ventilation from Messrs. Rich-

ardson & Co., Darlington; a fine octagonal house from Messrs. Mackenzie & Moncur, Edinburgh (sold on the ground for £170); garden seats from Messrs. Haughton & Thompson, Carlisle; boilers and lawn mowers from Messrs. Hartley & Sugden, Halifax; also lawn mowers from Mr. Parkinson, Ripon; summer houses and wirework from Messrs. Gibson & Sons, Edinburgh. Also wirework from Messrs. Bramhall; an imposing stand from Messrs. Goulding, manure manufacturers, Dublin and Cork; and an extensive seed stand, &c., from Messrs. Little and Ballantyne.

Such was the Show—a great Show unquestionably; but it is to be feared that the fine weather following the opening day, with the counter-attractions of the agricultural show, cannot render it a great success. One thing is clear, the officials—Mr. Baxter Smith, Mr. Thomson, Mr. Mounsey, and the Committee—have worked hard, and their assistants have been zealous—almost too zealous at times, carrying out their instructions in the unbending inflexible style savouring of military police.

Although the opening day was so disastrous the two following days were fine, and the railways brought thousands of visitors to the city and Exhibition. On the first day (Thursday) the receipts were £133 14s. 6d., the second day £494 6s., and on the third day £402, making a total of £1030 0s. 6d.; and this with the contributions and the rent of marquees for refreshments will, it is hoped, result in what the promoters so richly merit—a financial success. The prize-money was paid on Monday the 10th inst., the day on which the exhibits were removed.

At the luncheon in the marquee Lord Muncaster presiding, the guests had to approach the banquet through a puddle, sit on wet seats, eat soaked bread, wear their hats at table, and unfurl umbrellas.

NOTES AND GLEANINGS.

MONDAY, the 3rd, was a very wintery day, the thermometer never rising above 44°, and at night it descended to 35° at 2 feet above ground. Rain commenced on the evening of the 2nd, and continued incessantly for more than twenty-four hours. On the night of the 4th, after a bright day, the mercury at 2 feet from the ground fell to 33°. The grass was frozen stiff on the mornings of the 4th and 5th, but nothing seems to have suffered excepting the points of *Coleus* a little, and the flowers of *Commelina cœlestis*.—WILLIAM TAYLOR.

—We recommend cultivators of the *PETUNIA* to add to their collections some of Messrs. Carter & Co.'s "green-edged." The flowers are the finest and most varied we have seen.

—THE Water Lily tank and the fine Tree and other Ferns associated with it afford one of the most pleasing features of the CRYSTAL PALACE. *Nymphaea dentata* major and *Devoniana* contain many fine flowers, but *N. coerulea* has not flowered freely this year. It is noteworthy that these fine plants are treated as biennials. Seed is sown at the present time, and the plants are kept growing in small pots in a small aquatic house throughout the winter, and are transferred to the flowering tank in the spring. Seed has just been gathered from them and sown, and the flowering plants will be eventually removed. It is a little singular that these plants will not grow if much water is permitted to fall on the leaves. In the centre of the tank is a large fountain, which plays for a short time daily; near this fountain the Water Lilies will not grow—indeed, scarcely exist, but beyond the radius of its falling spray they grow luxuriantly.

—ONE of the most attractive of variegated plants for growing in pots for general decorative purposes is the VARI-GATED *HEMEROCALLIS*, *H. flava* variegata. We recently saw a good stock of it in Mr. Laing's Nursery at Forest Hill, and Mr. Thomson also grows it at the Crystal Palace. The leaves arch over in a most graceful manner, and their variegation is very pure and clear. It appears to come in the best condition when grown in an intermediate house or a warm greenhouse.

—A YORKSHIREMAN writes to us that he has seen it recommended by a great "authority" that *CEANOTHUS AZUREUS* should be grown in every garden having a sunny south wall. Our correspondent thinks the writer's experience of the plant must be limited, or he would have known that there are hundreds of gardens where, if planted, it would be cut down by the severity of the winter. It is a beautiful wall plant in the southern counties, but is too tender for cold districts.

—It is gratifying to notice that the valuable collections of plants employed in the decoration of the Agricultural Hall, and where they remained for more than a week, sustained little or no injury. The ventilation of the immense building appears to be excellent, and it has proved itself well adapted for the purpose to which it was devoted last week. The spikes

of *Gladioli* continued attractive throughout the period, and even such choice and tender flowers as those of *Dipladenia Brearleyana*, which were inserted in the moist carpet of *Lycopods*, continued fresh and bright for nearly a week. The decorations attracted large numbers of visitors, and we are informed that the great "floral concerts" have been very successful.

—Two cultivators from different districts inform us that Crawford's EARLY PEACH has resisted the inclement weather of the past spring better than most other varieties, and that this handsome-looking American sort is bearing good crop on the open wall.

—In July and August, writes a Yorkshire correspondent, our shrubberies exhibit too much green, too little colour. *Deutzia crenata* flore-pleno forms a fine upright bush 6 feet or more high, bearing profusely its fine, depending, double pinkish flowers, and is very fine; *D. scabra* is also fine. The ligneous Meadow-Sweet *Spiræa* are grand summer-flowering shrubs, especially *S. grandiflora*, white; *S. arifolia*, very graceful; *S. callosa*, rose, and var. *alba*; *S. eximia*, red; *S. bella*, rose; *S. argentea*, with silvery leaves; *S. Douglasi*, pink; *S. opulæfolia* *lutea* and *S. salicifolia* *carnea*, with many others. They grow freely and flower profusely in any free soil.

—ABUTILONS appear to be increasing in popularity for decorative purposes. The dwarf-growing free-flowering varieties, such as *A. Darwinii*, *A. roseiflorum*, &c., recently introduced appear to be great acquisitions, and the new yellow variety *A. Lemoinei* *syn. La Boule d'Or* is a plant of considerable promise. But perhaps the most useful for winter flowering is the white variety *Boule de Neige*, which should be grown largely where cut flowers are in great demand. It is not known by everyone that that sort forms a capital stock on which the pendulous mottled *A. vexillarium* may be worked. Mr. Spinks of Aston Park, Birmingham, thus grows *A. vexillarium*, as also does Mr. Thomson of the Crystal Palace, and the bright weeping standards are ornamental even when not flowering, and when in bloom are handsome dinner-table plants.

—Now that wild flowers are so scarce, what few we have at this time of year being completely obliterated by the long-continued rains, it is pleasing to see amid so much green something that will fix the eye. Few subjects can vie with the bright coral-red berries of the ROWAN TREE OR MOUNTAIN ASH (*Pyrus Aucuparia*), its fine umbrageous head of Fern-like foliage, from the points of its shoots bearing its clusters of berries, are far more enduring than flowers, attractive objects in shrubbery, park, and forest scenery, such as ought not to be neglected in making provision for when planting time arrives. It will grow anywhere; its upright and weeping forms, with the yellow-berried, deserving a place in the most select arrangements of trees of moderate growth. Also very conspicuous just now, as they have been for many weeks, are the bright scarlet berries in massive bunches of the scarlet-berried Elder, which, seen at any distance among green foliage, are very showy and effective, especially if in front be a good breadth of Darwin's Barberry; its clusters of shining deep purple berries having in contrast with the scarlet of the Elder a fine effect.

—LIMNOCHARIS HUMBOLDTI.—It is a pity this lovely and most floriferous aquatic is not more employed for outdoor work. It is one of the most effective plants for a tank or quiet bit of water. The small outdoor tank near the Victoria house at Glasnevin is nearly monopolised by this plant, and at this season few features of the garden are more attractive to the visitors. The tank is only about 10 feet in length and 3 feet in breadth, and in this circumscribed space we counted the other day over 160 flowers floating on the surface. —(Irish Farmers' Gazette.)

WINDSOR CASTLE.

LAST week a princely garden in the north was described and the masterly practice of its manager was noticed. Such a record cannot fail to stimulate other persevering and ambitious workers (for if a gardener is not ambitious he cannot excel) in a kindred but lesser field, and to urge them on in the path of duty, which sooner or later brings a reward. This week a garden in the south may be fittingly noticed—a garden which will always command attention—the garden of our Queen.

Windsor Castle is a majestic pile, and the view from the celebrated terrace, which is shown in the accompanying illustra-

tion, is one of dignity and grandeur. The chief residence of a long line of British monarchs is typical of the kingdoms which owe allegiance to the British crown—strong yet peaceful, and varied in elements of fertility and beauty. The views both from the terrace and on it are such as to command admiration, such too as are enjoyed not by the Royal Family alone, but also by thousands of Her Majesty's subjects, for the terrace is open to the public on the afternoons of Saturdays and Sundays, a privilege which again typifies the most cherished treasure of the nation—freedom.

From the commanding eminence is seen on the one hand the Crystal Palace at Sydenham and the Box Hills, and on the other the distant woods of Stanmore and Cliveden. The great schools of Eton and Harrow are still nearer, embowered in the foliage of a boldly undulated and richly wooded district. Towards the south the Broad Walk with its noble avenue of magnificent Elms stretches away into the distance, and to the north the precipitous side of the hill on which the Castle stands forms one of Nature's bold terraces, which the one on which we stand, grand as it is as a work of art, is puny by comparison. This, the eastern terrace, the Royal flower garden, is about 3 acres in extent, and is semicircular in form. The Broad Walk, which next the Castle is of course straight, is continued round the enclosure and close to the embattlements. From this elevated walk flights of steps conduct to the level of the garden—the plateau of flowers below. The slope of the terrace between the flights is of turf, as is the general level of the garden, soft and fine, and in the highest condition of keeping; two broad gravel walks also intersect the enclosure. In the centre of the garden is a fountain, but not a majestic one; by the sides of the walks are several examples of statuary; on the lawn are specimen shrubs and Conifers, and on the north side near one of the entrances is an orangery; the other entrance is at the corresponding corner of the Castle, the south side. The orangery is placed on the lowermost ground of the terrace, and towards this structure the lawn has rather a bold slope, on which are beds planted wholly with hardy Heaths. Mr. Jones some time ago suggested the erection of another structure near the orangery for the display of ornamental plants, and it is a little singular that when his plan of the proposed alteration was being considered and compared with some old plans of the terrace, it was found that a similar addition had been proposed eighty years ago, so similar that there was only 6 inches difference between the widths of the houses which had been suggested in the two instances. A want of time for consideration of the matter cannot therefore be urged as an excuse that a structure suitable for beautiful plants worthy of being associated with this beautiful terrace is not yet erected.

The floral decorations of the terrace are varied, and on that account are the more enjoyable. A long narrow border near the western boundary wall contains old-fashioned plants—garden (not exhibition) Roses, Antirrhinums, Phloxes, Mignonette, &c. The flower beds on the lawn are of considerable size and appropriately plain in shape; they are extremely attractive. Most of the beds contain shrubs and Conifers, Yews in variety, Retinosporas, Thujas, Euonymuses, &c. Between the shrubs are planted such rather tall-growing plants as Ageratums, Pentstemons, and Petunias, surrounded with Geraniums and edged with dwarfier plants of contrasting colours. The most effective Geranium on the terrace is Waltham Seedling; its profusion of crimson trusses are rich and glowing. Trentham Rose is also well and worthily grown, for its soft yet cheerful colour is very pleasing. As a scarlet Vesuvius is employed, and as a rosy pink Mrs. William Paul. Some of the most effective combinations in the terrace garden were centres of Ageratums interspersed with shrubs, with a broad and brilliant band of Waltham Seedling Geranium and an edging of Geranium Manglesii mixed with Lobelias. A centre of Cineraria maritima, band of Iresine, and edgings of Golden Feather and Lobelias had a fine effect. In one portion of the terrace are examples of carpet bedding, which looks attractive enough when closely examined, but it is not nearly so well adapted for the position as is the grouping of flowers in large masses and distinct colours. The many shrubs in the beds and specimens on the lawn require more supporting power than carpet bedding affords, and they also at the same time effectively prevent the bold masses of flowers from being in any degree overpowering. Near Her Majesty's apartments Mignonette is growing freely, a sweet simple flower which is now absent from many flower gardens of lesser note than this. The effect produced by the skilful grouping of trees and shrubs

is quite worthy of the fine terrace on which they are disposed, while the perfume from the older flowers—Roses, Phloxes, and Mignonette, render this beautiful flower garden additionally delightful.

From the terrace a broad drive leads through the Home Park, leaving Frogmore House on the right and the Royal dairy on the left, and conducts to the gardens. Near the Castle several acres of the park are kept as a lawn. The drive for a short distance is near the edge of the great natural terrace, where glimpses are obtained of the slopes below. For quiet, secluded, romantic scenery the slopes of Windsor are pre-eminent. At the bottom of the great dell a cool stream-meanders, reached by a series of twisting walks on the otherwise precipitous side of the declivity, which is probably 200 to 300 feet deep. The trees in this dell are thick and luxuriant, and Ferns flourish in their congenial home. A rockery of considerable extent is also formed, and from amidst the boulders dwarf Pinuses, Ferns, and other plants spring, while a streamlet trickles down its rugged bed.

The park, between the slopes and the gardens, contains some magnificent trees. Elms predominate. There are also old Oaks—historical trees, and thriving Wellingtonias. The drives through the park are many miles in extent; they are smooth, clean, and in excellent order, and the grass is kept as a lawn for 4 or 5 feet from the gravel. The labour incurred in the keeping of these extensive drives and their smooth green margins led Mr. Jones to devise a means of expediting the work, or in other words in having it better done and at less cost than could be effected by mere animal and manual labour, and he has succeeded admirably. The rolling of the gravel and the mowing of the side lawns is done by steam power. A combined engine of eight-horse power was designed by Mr. Jones, and constructed by Messrs. T. Green & Sons of Leeds. This rolls the gravel better than any horse roller could do it, and draws the mowing machine at the same time. It is also constructed to act as a fire engine and to work at the saw table. It is found very valuable, and is a credit to the designer and manufacturer.

The kitchen gardens at Frogmore are very extensive; the forcing houses and pits are also on a scale of considerable magnitude. The chief range of glass is 1132 feet long and 20 feet wide. The houses are neat, light, and durable. They were constructed for use rather than ornament, yet their very utility and good condition have a pleasing appearance. Every house, too, is occupied. There is not an inch of glass too much at Frogmore; indeed not nearly enough considering the enormous demands for fruit, flowers, and vegetables, and a large addition of glass is projected—something worthy of Royalty, and which it is hoped will be carried out. Formerly much of the Castle decorations were done by professionals, but now all the plants employed are grown in the Royal gardens, and everything is done under Mr. Jones's supervision. All the fruit and vegetables and flowers required by the Royal household, whether that be established at Windsor, Osborne, or Balmoral, have to be grown at and sent from Frogmore. That demand is enormous. Fruit has to be sent by the hundredweight, and vegetables by the truckload, and flowers in the same proportion. The great establishment is taxed to the utmost, and the best of management is required to sustain the supply. Every corner of every house and pit is occupied in the most profitable manner possible, and every inch of ground is closely cropped.

It is not necessary to refer in detail to the contents of the several houses. The structure at the east end, which is higher than the general range, is a tropical plant house, containing Bananas in a fruiting state and many ornamental-foliaged and flowering plants. At the other end of the range is the Camellia house; and it is noteworthy that although the aspect is south and the glass not shaded, that there is scarcely a scorched leaf to be seen, but on the contrary the foliage is of the richest green. That the plants receive the best of attention is undeniable. The remaining houses in the range are devoted to fruit culture—Vines, Peaches, and Plums. The fruit from many of them has been cut and gathered. The Peach crop has been good, as a remnant of it proves, a few remaining Barrington Peaches weighing 10 ozs., and some have been gathered of the extraordinary weight of 13 ozs.—right royal Peaches as none can deny. The trees are in admirable condition and contain not a semblance of red spider. Some of the vineries are planted with young Vines, which are in an excellent and highly promising state; others are older, yet bear valuable crops of useful fruit—valuable at least until the

younger Vines are established to sustain the supply, when the older will be removed by degrees, for some of them are beyond renovation. It is necessary to proceed cautiously in this matter, for there must not be any failure in the supply during any day in the year. Neither is there likely to be; for it is certain, judging from what has been already accomplished and the soundness of the preparations for the future, that the supply of Grapes at Frogmore, ample as it may have been in the past, will be still greater and better in the future. The young Vines which have been planted are making excellent growth, and some of them are bearing wonderful crops. Late Grapes continue until the 1st of April, when the first house of fruit from Vines in pots are ripe: and so the work goes on in one continual round. On the back walls of some of the houses Tomatoes are grown and in others Guavas, and even the little porches between the houses are filled with Grapes. Behind

this range of glass (in the centre of which is the gardener's commodious residence, in which Her Majesty has private rooms) are the young men's living rooms, reading room, fruit stores, Mushroom houses, packing sheds, and other offices requisite for the conduct of the establishment.

Between this chief range and the boundary wall is a large enclosed space filled with smaller houses for Vines, Cherries, Cucumbers, Melons, Strawberries, Kidney Beans and plants together with a great extent of pits for Pines, Potatoes, and general purposes. Pines are grown in deep brick pits, no path inside. The bottom heat is afforded wholly by leaves, and the plants are all planted out. Their number is great and their quality still more striking. Nowhere in the Queen's dominions are finer Pines grown than in the Royal Gardens. They are Smooth Cayennes, and it is not now and then only that a fruit of 8 and 9 lbs. weight is cut, but such fruits are

Fig. 45.—WINDSOR CASTLE—VIEW FROM THE TERRACE.

the rule. The simplicity of culture adopted, and the uniform and great success achieved, is something that the manager and his assistants may justly be proud of. They may be equally proud, too, of some houses of Grapes. They are half-span-roofed houses. The Vines are in splendid condition, the crop enormous and excellent, and the roots a network of feeders close to the surface of the ground. They afford a remarkable instance of the power of mulching, and these Vines afford altogether a fine example of Grape-growing.

Houses are devoted to Azaleas, ornamental-foliaged plants, flowering plants, and Ferns. There are also a few Orchids, and it is clear that everything receives skilled attention. Strawberry and Kidney Bean forcing is a great affair at Frogmore. Upwards of nine thousand pots of Strawberries are forced yearly, and many plants are now being planted out in pits to produce a supply during the time immediately preceding the ripening of the outdoor crops. Pits of Strawberries thus grown last year proved very valuable. Pit after pit are filled with Kidney Beans, and hundreds are also grown in pots for ensuring a supply from October until July, when the outdoor crops are in use. Mohawk and Fulmer's Forcing are the most popular varieties. Cucumbers are always in season, the most esteemed variety for summer and winter use being Hedsor Prolific. It is of medium size, a great bearer, handsome, and of superior quality. Other pits are devoted to salads and

other vegetables, and every favourable wall space is covered with Tomatoes. Asparagus is forced in beds, hot-water pipes being laid between the beds and shutters placed above them. The beds are forced every alternate year. On the borders in this enclosure are hundreds of Bouvardias, Salvias, Habrothamnuses, Solanums, Spiræas, and similar plants, which are potted in the autumn for winter and spring. They are much better when thus grown than when kept in pots during the summer. There are beds also of Stocks, Asters, Zinnias, &c., for affording cut flowers. These are extremely fine, some of the Asters being extremely rich in colour and well sustain the credit of the seedsmen—Messrs. Veitch.

On the boundary wall facing the south is to be seen what is a rarity this season. Scarcely ever was the crop of Peaches and Nectarines on walls so scant as during the present year, and trees really well furnished with fruit are few and far between. By far the finest crop we have seen is on this wall. The trees are heavily laden with fruit—in fact, the crop is a full and fine one. This is to be attributed to efficient protection and a sufficient yet intelligent use of canvas blinds. Mr. Jones has great cause to be proud of this splendid wall of Peaches. It is the reward of protecting thoroughly. Half protection, which was only within the means of many gardeners, was quite inadequate during the extremely inclement spring to save the crop of this tender and much-valued fruit. The wall

is upwards of 1000 feet in length, and a commencement has been made towards covering it with glass. Behind this wall is the garden stabling, and near it has existed for a long time an eyesore—a blotch on the fair face of this fine park. It was a corner of rubbish and a sluggish pond. The rubbish has been removed, the pond is being filled up, and the ground made preparatory to planting a "standard" orchard; not an orchard of standard trees, but of dwarfs of every known sort of Apples correctly named as a "standard" collection. Many trees have already been planted, and they are thriving admirably. The same plan is projected with other fruits—Pears, Plums, and Cherries. This is quite independent of the fruit supply for ordinary purposes. The object is somewhat of a national one, and if Mr. Jones is able to carry it out on the complete scale he has projected it will be worthy of the Royal garden and of the nation.

The kitchen gardens yet remain to be noticed—necessarily briefly. They are upwards of 30 acres in extent in five or six walled enclosures. Originally each garden had its separate fruit and name. Thus there was the Strawberry garden, the Cherry garden, the Plum and Pear garden, and so on. The plan is now undergoing a change, or rather the system of planting. Many of the wall trees are old and decrepid, and young trees have not flourished well. In the renewal the borders which have supported stone fruits, as Cherries and Plums, are to be planted with Pears, and *vice versa*; and the Strawberries are being removed—a wise arrangement, which is already proving its worth. On the north sides of the walls are Currants and Gooseberries for late use—full and valuable crops.

Vegetable culture is carried out on a great scale. The system resembles that adopted in the London market gardens—that is, not an inch of ground is wasted, but the best that is possible is made of every crop. The soil is heavy, costly, and hard to work; but by taking advantage of its peculiarity and the weather the supply of vegetables is maintained, and the walks and quarters are kept clean and free from weeds. Down the central walk are rows of dwarf trees trained as low arches. They have a novel appearance, but are not profitable. A few arches trained over the walk would enhance the appearance of this part of the garden, and fruit would probably be produced on them.

In the management of this great garden—together with the supervision of the Home Park—unremitting attention and well-directed skill are requisite. Special and substantial marks of recognition conferred on the chief manager afford the best evidence that these are forthcoming, and that Mr. Jones is equal to his great and arduous task. The staff of men is about 150. The established departmental foremen have comfortable lodges, and every attention is paid to the welfare of all. Her Majesty takes much interest in her garden, and her thoughtfulness and appreciation render the work of all pleasant—a labour of love.—J. WRIGHT.

AUTUMN FLOWER SHOWS.

WHAT a pity it is that many societies give horticultural exhibitions at all! Numbers of places hold what they call flower shows, which may be so in name, but are not so in reality. There is a tentful of some sort of plants and flowers, a good band, a refreshment tent, and fireworks to end up with. This is the bill of fare; but supposing the flowers were left out altogether, would it not be far better? They are entirely secondary, or tertiary, or anything else you like to call them, to the band and fireworks.
